observing the image on the ground-glass of the camera-back; some arrangement, therefore, for operating the fine adjustment from a distance is necessary. A very simple contrivance for this purpose, which has always answered with perfect satisfaction, consists of a piece of thin twine, which passes over the milled head of the fine adjustment (the latter being grooved to receive the cord) down to the edge of the board on either side of the microscope, one end passing through a screw-eye towards the floor, while the other is carried from the instrument by an occasional screw-eye along the further side of the board to any convenient distance, where it passes towards the floor; on either end of the cord are suitable balancing weights—fishing dipsies answer well—when by the slightest movement of the twine the fine adjustment is turned. The arrangement, when properly adjusted, is all that can be desired, by which a one-twelfth or one-fifteenth can readily and delicately be focused, and possesses the advantage over the much more complicated mechanical arrangements of but a nominal cost, and of being out of the way of the operator, and little likely to disturbance by an accidental knock.

A proper illumination forms an essential part of the apparatus. A good kerosene lamp with a flat wick should be used, the flame being turned with the edge towards the microscope, and being on a level with the axis of the stand; between the flame and the stage a large bull's-eye condenser is interposed about five inches in front of the stage, with the plane surface towards the flame, the latter being three or four inches further removed. Care should be taken to have the centre of the condensing lens and flame to correspond to the axis of the instrument.

For low powers, say from three inch to the half inch objective, no further condensation of light is necessary, but with higher powers the addition of an achromatic condenser is of decided advantage, being the most convenient means of obtaining powerful, as well as *graded* illumination. Especial attention should be given to having the light well centred and equally distributed over the field, the intensity being adjusted by the condenser to meet the requirements of the preparation to be photographed.

With an illumination arranged as suggested, the range of objectives which may be employed is, contrary to a seemingly prevalent idea, practically unlimited, as we have photographed with objectives ranging from three inches to one-fifteenth of an inch, giving from twelve to thirteen hundred diameters, with very satisfactory results.

The illumination is sufficient to allow the use of a cell of copper ammonio-sulphate; experience has shown us that the blue-cell is unnecessary with lamplight, as no trouble is found from discrepancy between the foci of the visual and actinic rays, since in the yellow light they are, probably, practically identical. With the two or three inch objective, the image is perfectly in focus, with all blue-cell or glass discarded. Similar conclusions have been taught by the observations of a number of others.

The plates which have seemed the most satisfactory are those known commercially as Eastman's "Rapid." With these the length of exposure will vary, with illumination, lens, and preparation, from three to twelve minutes; with medium powers, four-tenths to one-fifth, about six minutes will usually be satisfactory; with one-twelfth or one-fifteenth, a somewhat longer exposure is necessary.

Probably the greatest difficulty in photo-micrography is in obtaining an accurate focus. In order to conveniently see the image on the ground-glass when stationed at the microscope, a mirror should be placed at the end of the table opposite to the focusing screen, when the image will be conveniently reflected while working at the microscope. On finding the approximate focus, the operator takes his position at the ground-glass, and, by means of the arrangement already suggested, secures the exact focus. For many preparations the ordinary ground-glass answers perfectly; for very delicate structures, however, the plate-holder, with a piece of plain glass occupying the position of the sensitized plate, should be substituted for the ground-glass of the camera-back, when, by the aid of a focusing glass, the accurate adjustment is readily obtained. While by no means essential, yet a large, firm stand, with mechanical and rotating stage, will be found exceedingly convenient for work with the higher powers.

To insure satisfactory results, certain conditions should be fulfilled. Objectives with unquestionable definition are, of course, indispensable; flatness of field and sufficient angle to admit plenty of light being likewise important. The character of the preparation is also a vital condition of success, since not a little of the disappointment from unsatisfactory work is due to the attempted use of specimens totally unfit for photography. When sections, they should be as *thin* as possible, care being taken that they lie flat when mounted; but whatever the form of the tissue, whether section or not, it should be deeply stained and *well differentiated*, the last being especially important.

Regarding the purely photographic manipulations, it is beyond the province of these notes to speak, since efficient assistance may be obtained from many sources. While it is desirable that the plate should be developed soon after the exposure, in order to ascertain its quality, yet printing and finishing, and indeed all manipulations, may be left for the professional photographer. Such, however, being questions for each worker to decide according to circumstances.

While lamp-light by no means replaces sunlight for photo-micrography when much time is devoted to such work, or where the very highest amplifications are required, yet the simple method described offers pleasant and profitable employment for many an evening, and may be made the means of recording much that is interesting and instructive. By lamplight, at a very moderate cost, with the simple additions to the microscope described, any one may have the satisfaction of producing really good work, which, we know from experience, may equal that by the more complicated method by sunlight.

Were photography more generally utilized for illustration, microscopical science would be the gainer: the favorite diagramatic clearness of our drawings might be lost, but things would be represented more as they really appear.

MURMURS IN THE ABDOMINAL AORTA.

BY DR. EDWARD T. BRUEN,

DEMONSTRATOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

WHEN cases are reported it is desirable that they should be accompanied by post-mortem examinations, or, if not, they should claim notice by their rarity. The following does not conform to either of the above standards, but as it represents phases of clinical diagnosis in which serious disease is suggested, its contents may still claim some general interest.

All physicians have probably met with a class of cases in which abdominal murmur is combined with symptoms of abdominal aneurism more or less conclusive, and yet the diagnosis of aneurism would be erroneous. The intricacy of these cases varies in proportion to the character of the combined clinical ensemble.

My case-book records the history of a gentleman, aged thirty, with a family history free from inherited tendencies to pulmonary or arterial disease, and with a personal record positively excluding the possibilities of syphilis or abuse of alcohol. He was apparently suffering from nervous dyspepsia attended with the voiding of urine containing an excess of urea, oxalic and uric acids, and oxalates. Upon examination a murmur was heard midway between the ensiform cartilage and umbilicus. The murmur was peculiar in that it was removed on full inspiration and complete expiration, and, therefore, was audible only during the interval between these acts. The quality of the murmur lacked the hollow echo distinguishing a bruit, but corresponded with the blowing murmur induced by pressure of the stethoscope over the superficial arteries. There was severe pain on assuming the upright posture, accompanied by pulsation in the epigastric region.

These facts rendered the suspicion of abdominal aneurism tangible. The diagnosis became a question of exclusion by probabilities. The age and habits of the patient were adverse to aneurism by an etiological survey. The absence of positive tumor, of transmitted murmur, of thrill, and the want of constancy in the intensity of the murmur, all combined to place the question of aneurism among the remote possibilities of the case.

A close analysis of the prior history of the patient disclosed the fact that some years before he had suffered from an indistinct form of peritonitis complicating typhoid fever. This suggested enlargement of the mesenteric lymphatics as a possible cause of pressure, the excessively violent aortic pulsation being referred to serious vaso-motor disturbance, and presumably the pain was due to the throbbing of the aorta against the vertebra, as happens in aneurism.

Instance second: A young man of twenty-three years of age presented himself to me, complaining of a severe dull pain in his back, a pain more severe when he resumed the sitting posture to write or when walking than when lying down. There were also some sharp darting pains down the limbs. The pain had troubled him for six months before he applied for medical advice. Disease of the spinal chord, caries of the vertebræ, renal or pulmonary disease could be set aside. The examination of the arterial system was also negative, and there was no history of rheumatism in any form. Six months later the pain persisted as at first, although at times it had been decidedly mitigated. On auscultation, just below the ensiform cartilage, a short puff was audible, not unlike a dull systolic cardiac sound. This murmur increased in intensity during expiration; it was not transmitted into the femorals, but it was suggested on auscultation posteriorly over the last dorsal vertebra. There was no thrill, nor could any tumor be felt on abdominal palpation.

From the standpoint of diagnosis, the consideration of the personal history disclosed habits of perfect temperance, and the freedom from specific taint. His youth, and the family history (his father having died of old age, mother having died of phthisis), the local character of the murmur, and the absence of thrill or tumor, all negatived aneurism. Yet that a local lesion existed was clearly probable, and the query arose, could a local atheroma occur from a local inflammation due to strain or injury? Or might such injury have occasioned inflammatory changes in the tissues adjacent to the aorta distinct from the arterial, and yet sufficient to induce pressure upon the aorta, and thus produce a murmur? The patient had been a cricketer, and fond of outdoor exercise, and this rendered the hypothesis of a local injury more plausible. This case may be said to be incomplete, since so far no conclusion has been reached. It is useful, because it shows the shade of difference in the symptomatology between murmur in the abdominal aorta having a possible organic genesis, contrasted with the evidently functional.

The third example presents to us a similar murmur in the aorta in the epigastric region. The patient, a male, aged between thirty and forty, was admitted to the hospital suffering from chronic malaria, with congestion of the abdominal vessels and viscera. No other striking symptoms were noted, and the murmur vanished after a six month's course of treatment.

In example fourth, a murmur occurred in a patient in whom the etiological probabilities, considered with the age (which was over fifty-five years), rendered the diagnosis, by election, a local patch of atheroma.

These cases are representative of a number of a similar character which have come under my notice. Certainly, they establish an important clinical fact, that murmurs in the abdominal aorta are not infrequent, and that they are associated with quite various conditions, often specially obscure. It is preëminently important to make a guarded diagnosis, because very often the symptom is transient,

or associated with more or less remediable forms of pathological process, distinct from lesion of the aorta. Pain, one of the fundamental symptoms of aneurism, is often a positive element in these fictitious aneurisms.

To unravel these complicated cases in the absence of a recognizable tumor and characteristic murmur, the marked influence of etiological factors which predispose to arterial disease is probably a most useful ally. In 34 cases in Netley barracks, 17 had a distinct, and 5 a probable syphilitic history, 3 of associated syphilis with alcoholism, 2 with well-marked rheumatic diathesis associated with acute manifestations, and only 6 without report as to systemic condition. The same writer states that out of 117 cases, 46.1 per cent. of the cases gave undoubted syphilitic history, 6.8 per cent. a probable history of syphilis, 21.3 per cent. occurred in phthisical subjects, 5.9 per cent. with heart disease, 5.7 per cent. with various diseases, 14.2 per cent. without record as to constitutional state.[1]

Ziemssen states that aneurism is eleven times more frequent in the English army than in civil life. We must, then, admit that the ensemble of aneurism must nucleate a sufficient number of the characteristic symptoms, such as pain, tumor, pressure-symptoms, and characteristic bruit, or thrill, before we can convert the diagnosis of election into the diagnosis of demonstration. In instance third, the murmur was associated with hepatic congestion and venous repletion of the mesenteric circulation. Murmurs in such cases must be distinguished from venous murmurs, due to narrowing of the portal vein by pressure, or disease of its coats. This is readily accomplished by observing that venous murmurs are continuous, and are not synchronous either with the systole or diastole of the heart. It is posssible that in some of these cases enlarged mesenteric glands in the vicinity of the pancreas, or indeed that organ itself, might produce the pressure. The etiology, however, of abdominal murmurs is very obscure, and one must be content to recognize their occurrence, since the absence of an autopsy has frequently prevented ultimate study. The murmurs usually disappear after appropriate alterative and tonic treatment. The case instancing a patch of local atheroma has been cited, because murmurs having this etiology occur, and the pathology has been demonstrated by post-mortem examination.

January 10, 1883.

HOSPITAL NOTES.

CITY HOSPITAL OF EVANSVILLE, INDIANA.

FRACTURED PELVIS.

(Reported by L. D. Brose, M.D., Ph.D., demonstrator of anatomy in the evansville medical college.)

S. V., German, æt. 58 years, single, fell through a hatchway on the first floor in a furniture factory, striking the cellar floor with his left hip. He was unable either to rise or walk after the fall, and was brought to the city hospital suffering great pain. Here the physician in charge examined him and administered an opiate to alleviate his suffering. The accident happened about eight o'clock in the morning, and I did not see the case until about four o'clock in the afternoon, when the patient presented the following condition: pulse rapid and feeble; surface cold, and the system laboring under shock.

He complained of pain about the left hip; was unable to lift the leg or rotate the limb. There was considerable bruising of the tissues in the region between the great trochanter and the crest of the ilium, pressure here causing acute pain. There was no eversion of the foot, and on rotating and extending the thigh, I failed to elicit crepitus. On measuring from the anterior superior iliac spine to the internal malleolus, and from the upper edge of the great trochanter to the median line of the abdomen, no shortening could be detected either in the shaft or neck of the femur of the injured side. Acute pain was also produced by pressure over the symphysis pubis and on exerting pressure over the two iliac crests, but no distinct crepitus was thus elicited. Crepitus and much pain, both deep-seated in character, were produced by flexing the thigh at right angles with the body and strongly abducting the limb. A catheter had not been passed into the bladder, and on inquiry I learned that he had passed his urine an hour previous, but that the attendant had thrown it away without examination. From the nature of the injury, the seat and character of the pain, and the absence of any shortening or eversion of the thigh, I diagnosed a fracture of the pelvis running into the acetabulum. A broad bandage was applied around the pelvis, sand bags placed along the thigh, and a lotion of lead water and laudanum ordered for the contused region. His evening temperature was 98.2°, pulse still rapid and feeble, but his general condition was comparatively that of comfort. The following morning the abdomen was much distended, very tympanitic, tender on pressure, and the patient complained of pain in the left breast. Auscultation disclosed a localized dry pleuritic friction murmur, and the cardiac apex beat displaced towards the right. There was no increased dulness on percussion, and on inquiry from the patient I learned that several years previous he had had an attack of pleurisy.

A turpentine stupe relieved the pain in the left breast, and a large one over the belly also lessened the abdominal tympanitis. The circulation continuing poor and the extremities cold, a mixture of tr. opii, tr. belladonnæ, and carb. ammoniæ was ordered, together with hot bottles to the feet. The evening temperature was between 99° and 100°, pulse continued feeble; ordered milk punch twice daily, and the turpentine stupe to the belly to be repeated. Examination of the urine by the resident, Dr. Gudgel, disclosed no albumen. Next morning I found the patient much improved, having rested well during the night; tympanitis less, and some return of the appetite. On the fourth day an enema of castor oil and turpentine was administered, which moved the bowels freely. The patient continued to improve, and on the seventh day of his admission, the tongue being heavily coated and the bowels constipated, ordered ol. ricini and syr. rhei aromat., each half an ounce. This produced free evacuation, the tongue cleaning in the course of a few days, while his appetite and general condition improved very much. The swelling over the seat of the injury being now much diminished, the lead water was discontinued, and a simple broad bandage retained around the pelvis.

On the thirteenth day of his injury, Dr. E. Linthicum being in the house during my visit, I asked him to see and examine the case with me, as the diagnosis prior to my taking charge of the case had been that of impacted intracapsular fracture of the femur, and my

[1] Med.-Chirurg. Trans. for 1876.

own diagnosis had since been questioned. On measurement we detected about a quarter of an inch of shortening in the length of the limb, but no shortening in the neck of the femur. Requesting Dr. Linthicum to place his hands over the great trochanter, I rotated the limb, but only caused the man pain without eliciting distinct crepitus. At the Doctor's request, I exchanged places with him while he rotated the thigh, but I could detect no crepitus, and our examination producing great pain, the patient sitting up in bed saying he could not breathe, we discontinued our manipulation. The seemingly asthmatic attack continuing and the face becoming livid, I gave him a drachm of Hoffman's anodyne. This failed to mitigate his dyspnœa and substernal pain. I next prepared a solution of morphia and atropia, but before I could inject it he asked for the bed-pan, had an evacuation from the bladder and rectum, became pulseless at the wrist, and death ensued in a few minutes, the intellect remaining clear with no signs of palsy up to the last.

Necroscopy.—Extensive old pleuritic adhesions over the left lung, the lower lobe of which was highly emphysematous, exhibiting several large blebs on its anterior surface near the base. The lung tissue was otherwise healthy. Over the right lung there were also adhesions, but of minor extent, and the lung substance itself was normal. Pericardium normal. Heart in diastole softened, but not enlarged. Cavity of the right ventricle contained two small clots, soft in consistency, of dark color, and post mortem in character. Valves normal. Left ventricle normal in size and without valvular lesions. Abdominal cavity free from hemorrhage. Spleen enlarged. Liver and kidneys normal. Dotted over the small intestines were flakes of yellowish lymph. Exarticulation of the hip-joint; neck of femur unfractured, and head of bone normal. Running from the acetabulum upwards to the sacro-iliac junction was a large simple fracture of the ilium, without any displacement of the fragments.

The case is one of great interest from the occurrence of sudden death whilst the patient had been daily improving and gave every promise of a good recovery. During the entire time he was in my charge I noticed that his extremities became cold after the slightest exposure; that the pulse was easily compressed, in fact, that his nutrition was poor and that he had a very weak heart. Part of his treatment consisted in the daily use of hot bottles to the extremities, to keep up their warmth. The cause of his death was most probably due to cardiac failure, arising either from the acute pain experienced whilst we abducted the thigh, or from his suddenly rising in bed and thus overstraining an already weakened heart, or both causes operated together.

The case illustrates an important point in the treatment of such subjects, that we make use of stimulants from the beginning; that we guard against sudden changes in position, such as suddenly assuming the sitting posture after having been in the supine position for a number of days, and that we take especial care how we inflict pain by unnecessary and repeated examinations of the injured parts.

MEDICAL PROGRESS.

CYST OF THE SPLEEN.—A case is reported in the *Deutsche Med. Zeit.* of a man who received an injury from a falling brick in the region of the spleen ten years ago, which caused the patient considerable pain for five or six days. One year before the operation, or nine years after the injury, a tumor about the size of a fist made its appearance in the left lumbar region, increasing in size very slowly at first, but at the end of a year the growth assumed the dimensions of a child's head. The tumor was slightly movable and presented a certain amount of fluctuation. The author made an explorative laparotomy and, when seeing he had a cyst of the spleen to deal with, concluded to make a radical operation. The cyst was punctured and a large quantity (1300 grammes) of straw-colored liquid escaped. The walls of the cyst were very much attenuated, and at a point or two it was adherent to the peritoneum. All the vessels connected with the growth were carefully ligated with catgut in two places, and the tumor was removed. Very little bleeding followed, the pedicle was returned, abdominal wall sewed up and wound treated antiseptically (no drainage). Patient recovered without any untoward symptoms, and was able to walk around in two weeks. Four weeks after the operation patient complained of pain and weakness, and presented a peculiar sallow appearance, but at the expiration of four and one-half months he had recovered sufficiently to follow his occupation. Shortly after the operation (about eight days), the author examined a specimen of the patient's blood, finding an increase of the white blood corpuscles and a diminution of the red. The condition of things gradually changed, as the patient was improving, and at the end of four months blood was perfectly normal. Ten months after the operation patient is healthy, and no sensitiveness over the region of the spleen.

The observations in this case are of great importance to the physiologist. They prove, in the first place, that the spleen can be removed from the animal organism without any special danger; second, the removal of this organ causes a temporary disturbance in the formation and relative proportion of the blood corpuscles; and third, its function is to change the white blood corpuscles to red ones. The observations in this case correspond exactly with the experiments made on animals.—*Cincinnati Lancet and Clinic*, March 10, 1883.

BASILYSIS FOR DYSTOCIA FROM HYPERTROPHIC ELONGATION OF THE CERVIX UTERI.—Three years ago PROF. SIMPSON described an instrument for breaking up the fœtal head, and he has just reported a case in which it was used with success on account of dystocia from cervical elongation. After anæsthetization the uterus was kept fixed by pressure on its fundus with one hand, while the other fixed the head by pressure above the pubes. The vault having been perforated on the side next the anterior wall of the cervix, the point of the basilyst was guided to the anterior part of the base, in front of the sella turcica, and screwed in to the shoulder. When the blades had been separated it was felt that the structures were broken up. To effect more complete comminution the instrument was again applied just behind the sella turcica, and on its withdrawal the base of the skull felt relaxed. No blood escaped during this proceeding, showing that the child was dead, and the maternal structures were not injured. Some brain matter escaped during the operation, and the rest was evacuated by douching. Traction on the head was made by the fingers, support and counter-pressure being applied to the lips of the cervix during its extraction. The head was delivered easily, but difficulty was experienced with the shoulders, the circle of the os fissuring in different directions, especially at the left side, where the parts were somewhat thin. The distention by the shoulders also wounded the left nympha and adjacent portion of the vestibule anteriorly and the right posteriorly. The cervix was well douched with carbolized water, and digital pressure applied to the wound of the left nympha in order to stop the bleeding. The placenta was expelled in about

twenty minutes, and shortly after some (post-partum) hemorrhage occurred. Ergotin was injected freely into the buttocks. The patient's pulse was now very feeble, and her condition critical, from the loss of blood with her previous weak state. Ether was administered intramuscularly, and stimulants and digitalis by the mouth. Bandages were applied firmly to the legs from below upwards, and combined external and vaginal pressure to the uterus maintained for about two hours.

The patient gradually rallied, and the passages having been again carefully douched with carbolized water, the lacerated surfaces were dusted with iodoform before the patient was put to rest. The child was born at 1.20 P. M., thirteen hours and twenty minutes after commencement of labor; third stage, twenty minutes.—*Edinburgh Med. Journal*, March, 1883.

Prolonged Diphtheria.—Dr. de Gassicourt (*Rev. Mens. des Mal. de l'Enfance*, Jan. 1883) contributes a paper with the above title, by which term he does not mean either the chronic or the subacute form of the disease, but he would thus describe a class of cases which (in their early history) have nothing to distinguish them from ordinary cases, but which, instead of terminating either in death or recovery within a period fixed in the paper at a month, continue longer, as evidenced by the "incessant reproduction" of false membranes. In other words, by prolonged diphtheria he means diphtheria "prolonged beyond the ordinary limits. To the question of why such cases should occur, he finds no answer. Attention is drawn to the fact that in the reported cases there was no evidence of systemic poisoning during the period of reproduction of false membranes, and this is explained on the supposition that the membrane is merely a product of the disease, and that in no case does it either primarily or secondarily cause systemic poisoning. Two cases are detailed, in one of which, after an ordinary attack lasting twenty-seven days, the child completely recovered its health, but false membranes continued to form for nineteen days; and, in the other, a hospital interne was compelled to travel for nine months after his convalescence before the formation of false membranes ceased. Several cases are then considered under the designation of croup, but which were, the author states, instances of diphtheria of the air-passages, as evidenced by their clinical history—the occurrence of albuminuria, etc. He holds that cases may be prolonged, 1st, where tracheotomy is unnecessary; 2d, before tracheotomy becomes necessary; and 3d, after its performance. Instances are given where the disease was prolonged from fifty-five to one hundred and fifty-one days. In all such cases the author states that any danger which may arise will be of a mechanical, and never of a toxic, nature.—*Edinburgh Med. Journal*, March, 1882.

Nephrectomy.—At the meeting of the Academy of Medicine in Ireland, held December 8, 1882, Mr. Stokes, Secretary of the Surgical Section, on behalf of Mr. F. J. O'Reilly, exhibited a kidney, which Mr. O'Reilly had removed by lumbar section from a patient, aged 26, in the Trim Union Infirmary, who suffered from symptoms of disease in the right kidney and pus in her urine, together with a constant desire to pass urine. The quantity passed daily was fairly normal, and the specific gravity ranged from 1015 to 1020. A favorable opinion was thus entertained of the capabilities of the left organ to discharge the increased functions with which it was about to be taxed. The operation was by the vertical lumbar, or postperitoneal method, and was performed antiseptically. The vessels and ureter were secured by a whipcord ligature. The external wound was closed with interrupted sutures, and antiseptic dressing was applied. The patient suffered from vomiting during the late stages of the operation. The gland weighed eight ounces, and an abscess-cavity at its superior extremity contained about two ounces of pus. The vomiting and depression, which manifested themselves during the operation, continued, and the patient sank and died forty hours after the operation. About an ounce of urine was drawn off with the catheter previously to death, and did not contain a trace of pus. The kidney was a specimen of primary tubercular disease. A *post-mortem* examination was not obtained, but the wound was investigated, and found free from blood-clot and perfectly aseptic.—*British Med. Journ.*, January 6, 1883.

The Action of Muscarin.—Franz Högyes, in a paper on the action of muscarin on the circulatory system, shows that muscarin lowers the functional activity of the central nervous system, and after a short time paralyzes it, whilst it at the same time slowly lowers the excitability of the peripheric nervous system. He demonstrates that the dilatation of the vessels after injection of the muscarin is an immediate consequence of the paralyzing action of this poison on the vasomotor centre. At a later period there appears to be diminution in the excitability of the smooth muscular tissue of the body. Muscarin inhibits the action of the heart, because it lowers the excitability of the automatic nerve centres in the organ, and in fact abolishes it; and with this action it causes a gradual diminution in the excitability of the muscular tissue of the heart itself.—*Lancet*, February 24, 1883.

The Production of Monstrosities.—The recent studies of M. Camille Dareste have confirmed his earlier views as to the production of monstrosities. He shows that the eggs may preserve their vitality and develop in a perfectly normal manner even if the temperature of the incubator falls several degrees below the temperature which is usually regarded as essential to normal development. Abnormal deviations in development are much more likely to be produced when the temperature becomes elevated over the normal degree, and when some time is allowed to elapse between the laying and incubation of the egg.—*Revue Scientifique*, February 24, 1883.

Epithelium of the Cervix removed during Pregnancy without causing Abortion.—At the meeting of the Obstetrical Society of London held February 7, 1883. an account of this case was read by Dr. Godson. The patient, aged 35, had suffered for twelve months from yellowor watery fetid discharge, latterly from hemorrhage and occasional pain. Till then she had been healthy. The cervix was enlarged and ulcerated; the uterus was mobile. The cervix was removed by the écraseur four days after the cessation of hemorrhage believed by the patient to be menstrual; no bad symptoms followed. Nine days after the operation a sound was passed into the uterus, and four days after this a fœtus of about eight weeks' development was expelled. The author remarked that he believed the abortion was due to the use of the sound, and not to the operation. He advocated the removal of cancerous growths, if possible, at any stage of pregnancy. His case supported the view that cancer favored the occurrence of pregnancy, the patient not having been pregnant for six years previously. He remarked on the patient's previous good health, the late onset of pain, and the importance of not pulling down the cervix when using the écraseur.—*The Lancet*, Feb. 24, 1883.

TRANSFERABILITY OF ALOPECIA PREMATURA.—LASSAR and BISHOP (*Monats. f. prakt. Derm.*, July, 1882) relate some experiments which seem to point to the contagious nature of alopecia prematura. A young man of twenty-five, himself healthy and of a family not predisposed to baldness, had become bald over the front part of the head within five or six years. The hair near the bald part was lustreless, and came easily out when pulled, while numerous fine scales were clustered over the surface. The hair and scales which were brushed off were mixed with vaseline to form an ointment, and this applied to the skins of a healthy rabbit and guinea-pig. These, in the course of rather more than three weeks, became bald over the parts on which the ointment had been applied, and an abundant scaliness was produced. The scales and hairs from these animals were likewise made into an ointment, and this caused marked baldness in a rabbit to whose skin it was applied. From it, again, a third was infected, and it became the baldest of all. In the meantime the head of the young man was treated by washing with tar soap, and application of corrosive sublimate lotion, solution of naphtol, and carbolic oil. This was continued eight weeks, when a new and stronger growth in the bald and partially denuded parts was plainly visible. An ointment made from the fallen hairs, now only $\frac{1}{60}$ part in weight than before treatment was begun, when applied to a rabbit, caused no morbid symptoms.—*Edinb. Med. Journ.*, March, 1883.

THE VENOM OF THE COPPERHEAD.—DR. ISAAC OTT draws the following conclusions from an experimental study of this subject:

1. The venom of the copperhead is weaker in toxic activity than that of the rattlesnake.
2. The heart, with both kinds of venom, becomes greatly prostrated, and in rapid deaths is their main cause.
3. The venom of either snake does not affect the sensory nerves.
4. The sensory centres are affected by both venoms.
5. The muscular excitability continues to be little affected at the time of death by the poison of the copperhead.
6. The two venoms greatly resemble each other in physiological activity.
7. The cardiac force, rhythm, and frequency are lowered by both venoms.
8. The arterial tension is greatly lowered by both venoms.
9. The blood, after copperhead poisoning, shows no microscopic changes of its globules, or any difference in its spectrum.—*Virginia Medical Monthly*, February, 1883.

EXTERNAL ŒSOPHAGOTOMY FOR DYSPHAGIA.—H. HADLICH reports the case of a man in whom dysphagia was caused by lordosis of the cervical vertebræ and enlargement of the cricoid cartilage. The œsophagus was opened in the neck, and stitched to the edges of the wound. No disease existed in the walls of the œsophagus. Feeding was carried on through the opening in the neck for a while, when the patient learned to swallow in the normal way, and the fistula into the œsophagus was closed. For a time all went well, but in about six months the dysphagia again appeared, but could be overcome by repeated dilatation. Death finally occurred when away from the hospital. No post-mortem could be obtained.—*Centralb. f. Chirurg.*, October 28, 1882.

BOROGLYCERIDE IN THE TREATMENT OF PURULENT OPHTHALMIA.—MR. HARTRIDGE, of London, has for several weeks tried the effect of boroglyceride in a few cases of purulent ophthalmia which have come under his care at the Central Ophthalmic Hospital. The way in which he has employed it in purulent cases has been to evert the lids, and, after cleaning away all pus and secretion with cotton-wool, to brush the mucous membrane over with a 1 in 10 solution of the boroglyceride, taking care to introduce it well under the upper lid. This has been repeated daily, and in the interval the mother has been instructed to bathe and clean the eyes and lids every hour with a 1 in 40 solution. No other treatment was used, and the cases began to improve at once, being usually well in from eight to ten days. Where one eye only was affected, he has, after brushing over the lids, applied a piece of lint soaked in 1 in 20, covered with a pad of cotton-wool, and bandaged the eye, with the result of preventing the sound eye from becoming attacked. In all the cases the cornea was unimplicated.

Boroglyceride is an antiseptic introduced by Prof. Barff, and has been used considerably in Germany in surgical cases, and also for domestic purposes, the preservation of meats, etc. It is made by the chemical combination of boracic acid and glycerine in certain proportions, whereby a new compound, boroglyceride, is formed.

The following are some of the advantages of this antiseptic: It is readily soluble in cold or hot water; it is odorless, tasteless, and unirritating; a 1 in 10 solution dropped into the eye causes scarcely any smarting; and, according to its introducer, it is innocuous. —*Lancet*, February 17, 1883.

SPECIFIC VULVO-VAGINITIS IN INFANCY.—Simple vulvo-vaginitis is not rare in children, and is most frequent before the fifth year, and then again at the time of puberty. Out of 3,921 girls treated at DR. RICHARD POTT'S (*Jahrbuch für Kinderheilkunde*) clinic, from 1876 to 1882, there were 44 cases of obstinate, long-continued, more or less profuse, purulent or muco-purulent discharge. These cases, which continue so long, and are so severe, the author claims are, almost without exception, specific and contagious. The author emphasizes this point, and was able to demonstrate, in nearly all of his cases, that the mother either had gonorrhœa or syphilis. That the membrane of the vagina is not affected as often as that of the eyes, is explained by its more protected situation and shorter exposure during delivery. In fact, contagion, in most cases, takes place after delivery, from fingers, towels, sleeping in the same bed with parents who have gonorrhœa, or directly from one child to another. These are by far the most frequent methods. In only two of the above cases could direct contagion from the male penis be proved, in both of which the fact was explained by the superstition among the peasantry that connection with a virgin instantaneously cures clap. In six of the forty-four cases, the children had congenital syphilis with marked manifestations. It was found, however, that general treatment was not sufficient to cure the discharge, even though it entirely removed the other manifestations.

The author's method of examination is very thorough, including speculum and microscope, but there is not great difficulty in making the diagnosis.

His treatment, for a long time, has been about what is generally recommended, and has been very unsatisfactory. He now recommends two things. The first is the rupture or complete removal of the hymen, in very obstinate cases. This usually brings about a rapid cure. But lately he has found a remedy which he thinks will make even this unnecessary. It is iodoform. He used it first in powder form, but that being too troublesome, he now uses it in the form of bougies, five to eight cm. long, and as thick as a small lead-

pencil. These are passed in till the lower end is just within the hymen. No intoxication ever occurred, and the effect is "eclatant." In only two cases has he had to put in more than one bougie.—*American Journal of Obstetrics*, March, 1883.

Gastrostomy for Impermeable Carcinomatous Stricture of the Œsophagus.—O. Kappeler performed gastrostomy on a man sixty-nine years of age, who was almost at the point of death from starvation, on account of stricture of the œsophagus. After opening the peritoneum the stomach was stitched to the edges of the wound, and Lister's dressing applied for four days; union was then firm, and the stomach was opened. No febrile reaction followed the operation, and the patient's general condition greatly improved. Death occurred in four weeks from the appearance of the disease in the lungs.—*Centralb. f. Chirurg.*, October 28, 1882.

The Treatment of Cholera Infantum by Koumiss.—A. Krasin (*Aerzt. Nacht. aus St. Petersb.*) in this paper repeats numerous published observations; and, having regard to them and to his own experience, the writer warmly recommends the employment of koumiss in the above disease. In cases of collapse, he uses the ordinary koumiss on account of its great stimulating power, but as a rule he has recourse to the variety which has been allowed to ferment for one day only. *Edinburgh Medical Journal*, March, 1883.

Tri-chlorated Phenol as a Disinfectant in Gangrenous Wounds.—Dianin (*St. Petersb. Med. Woch.*, No. 38, 1882) states that the compound which he describes under the above name is made by mixing carbolic acid and chloride of lime. He summarizes its properties and clinical uses as follows:

1. Tri-chlorated phenol is twenty-five times more powerful as a disinfectant than carbolic acid.
2. Even very small quantities prevent fermentation entirely.
3. It is a very powerful antiseptic—more powerful, indeed, than any of those in common use at present, such as the permanganates, solutions of chloride of calcium, carbolic acid, thymol, salicylic acid, and boracic acid.
4. It is not only a powerful disinfectant, but it destroys evil odors as well; the peculiar odor of the compound itself can be masked by mixing it with oil of lavender (five drops to the grain).
5. When applied in substance to a wound or ulcer, it is slightly irritating, but the solution has no irritating properties.
6. It is undoubtedly useful in the treatment of soft chancres, and in diphtheria.
7. The salts of tri-chlorated phenol possess the same disinfectant properties that the phenol itself does, and its soda salt is free from odor.
8. The lime salt of tri-chlorated phenol is cheaper than carbolic acid.—*Virginia Medical Monthly*, February, 1883.

The Age of Puberty in Women in Finland.—From the histories of 3,500 women in Helsingfors, Dr. G. Heinricius states that the average age at which menstruation commences is 15 years 9 months and 25 days.—*Centralb. f. Gynäkol.*, February 3, 1883.

Iodoform in Diabetes Mellitus.—Prof. Bozzolo (*Gazetta degli Ospitali*, Feb. 4, 1883), following up Moleschott's researches, has tested the action of iodoform in the treatment of diabetes, and with good results. He has given as much as thirty grains daily. In one slight case glycosuria was almost completely suspended; in a very severe case the quantity of sugar was reduced; in both patients diminution in the amount of urine was noted. Balp and Negro, investigating the subject in Bozzolo's clinique, have come to the conclusion that the administration of iodoform in diabetes, in doses of from fifteen to thirty grains, diminishes the amount of urine and the elimination of sugar, the number of red globules and of hæmoglobin, and likewise reduces the arterial tension.—*Lancet*, February 17, 1883.

Gastrostomy for Carcinoma of the Cardia.—E. Rochelt reports the case of a man aged 70 years, who had for a year and a half suffered from difficulty in swallowing, and in whom finally it became impossible even to swallow liquids. A gastrostomy was therefore performed through an incision five centimetres long, parallel to the lower border of the ribs. The stomach, which was very much contracted, was drawn through this opening, incised, and then stitched to the edges of the wound with thirty-five catgut sutures. Death occurred three days after the operation, from weakness. It should be stated that for five days before the operation the patient was unable to swallow liquids. No autopsy was permitted.—*Centralb. f. Chirurg.*, October 28, 1882.

An Improved Method of Circumcision for Congenital Phimosis.—Dr. Neil Macleod recently operated on a child of two years in whom the orifice of the prepuce scarcely admitted the point of a probe, but by dilating this orifice forcibly with "sinus forceps," and the addition of a few tiny snips with scissors round the margin of the orifice thus dilated, the foreskin could be drawn back until the point of the glans showed itself. Further retraction was prevented by the adhesions referred to, but these were easily broken down by means of a probe passed between the prepuce and the glans, and this done until the corona glandis was exposed in its whole extent. The prepuce was next replaced forwards, and the amount to be cut off was marked by a clip arrangement made by tying two ordinary directors, groove to groove, at one end and slipping the prepuce into the clip formed by the untied ends. Three carbolized silk threads were then passed through the prepuce at equal intervals close to the clip on its proximal side, the glans being guarded as the needle was passed, and each thread being of sufficient length to form *two* sutures. The prepuce in front of the clip was then cut close off, the clip separated, the penis released, vessels twisted, the threads fished up with a blunt hook from the now enlarged preputial slit, cut and then tied on each side. The orifice in the inner or mucous layer of the prepuce can then be slit with scissors down to the corona, but this is unnecessary if the clip is put on so that the line of section runs in the direction from the corona to the orifice of the urethra.

The surface of the glans being anointed with vaseline, a plug of absorbent cotton dipped in one to twenty solution of boroglyceride made an excellent dressing, and was kept applied by a bandage passed round the abdomen, knotted behind, and the two ends brought forward between the legs over a piece of light macintosh or oiled silk, the bandage ends diverging so as to include the genitals, then converging and being looped through the bandage crossing the abdomen. The absorbent pad was changed every time that urine was passed. Healing took place by first intention, and not a trace of odor was detected from first to last. Carbolized catgut sutures would have been better than silk, as they do not need to be removed.—*Edinburgh Med. Journal*, March, 1883.

THE SYMPTOMATOLOGY OF PERICARDITIS.—This paper by ROSENBACH (*Deutsche Med. Wochen.*, Nos. 44–46, 1882), is founded on a consideration of five cases of pericarditis, in all of which, besides friction sounds at the base, there was a murmur at the apex apparently of mitral origin. In the first two cases mitral insufficiency was diagnosed, but was not found on post-mortem examination. The succeeding cases were then more carefully studied. The grounds for considering that in none of them was there insufficiency were, that one came to the post-mortem table, and that in the other two the murmur gradually became fainter and ultimately vanished as the pericarditis improved, while no symptoms of valve lesion showed themselves. In character the murmur in those cases was long and very distinct; the first part of it was blowing, and it invariably ended in a whistle. The heart sounds were distinctly audible. Usually the point of maximum intensity was outside the apex beat, and the line of propagation more marked towards the axilla than towards the base of the heart. Pressure on the intercostal space, where it was best heard, caused no alteration in contrast with endocardial murmurs, which, as a rule, become weaker on firm pressure being applied. In one case the murmur disappeared when the patient lay on the right side. The writer suggests that the presence of this murmur may prove useful in diagnosing between pericarditis and pericardial pleurisy, and also that it may account for some of those cases in adults where a systolic apex murmur exists without any other indication of valvular disease.—*Edinburgh Med. Journal*, March, 1883.

PERCHLORIDE OF IRON IN SKIN DISEASE.—DR. CARSARINI (*Rev. Clin. di Bologna*) gives the following results:

1. Perchloride of iron is a most efficacious remedy in purpura hæmorrhagica.
2. In the chloro-anæmia accompanying certain skin diseases—as rupia, eczema, impetigo, etc.
3. Its external use is very favorable in scrofulous and syphilitic ulcers.
4. Squamous affections are markedly modified by applications of a liniment of perchloride of iron.
5. It may be used as a lotion, dissolved in two or three parts of water, or as an ointment—one, two, or three grains of perchloride of iron to thirty grains of vaseline [cosmoline] or lard. The author has used it in psoriasis, in the form of a pomade—ten grains of iron, thirty grains of lard or glycerine.—*Virginia Med. Monthly*, February, 1883.

THE RELATIONS BETWEEN THE TIMES OF OVULATION, FECUNDATION, AND COPULATION.—PROF. PANUM reports a case which seems to prove that the human spermatazoa may preserve their vitality in the genital tract of the female for as long a time as three weeks. A woman, aged 43 years, menstruated from April 3d to 5th, had connection with her husband on April 10th, and did not menstruate or copulate again until June 8th, when a slight hemorrhage occurred, followed by abortion on June 10th: the fœtus was perfectly fresh, and is stated by Prof. Panum to have been from four and a half to five weeks old.—*Nordiskt Med. Arkiv*, 1882, Bb. xiv. m. 26.

A NEW FORM OF POSTERIOR LUXATION OF THE SHOULDER.—F. BOTTEY reports the case of a woman, aged 78 years, who fell and dislocated her right shoulder. The head of the humerus could not be detected, either under the acromion, or in the infraspinous fossa, but was found two fingers' breadth below the acromion, behind the outer border of the scapula, lying in the wall of the axilla, so that a deep depression was formed between the head of the bone and the acromion. The author describes this variety of luxation as downwards and inwards, or retro-axillary. It is also worthy of note, that the arm was about half an inch shortened, that it did not stand off from the body, and that it was in a position of moderate supination with the elbow directed forwards. Reduction was readily accomplished by direct pressure on the head of the humerus.—*Centralb. f. Chirurg.*, Jan. 6, 1883.

CHALAZION.—Those foreign bodies which accumulate in the orifices of the Meibomian ducts must be removed either by skilfully pressing them out through the excretory orifices or by laying open the duct and removing them. Saline aperients and a course of the iodide of iron with occasional doses of quinine, usually put an end to the disposition to the formation of these bodies. A good plan is to dilute ten minims of strong commercial acetic acid with one ounce of distilled water, and apply to the closed lids by saturating small pieces of sheet lint and laying them over the lids. These applications may be kept up for an hour at a time every day until perceptible relief is manifest, when the duration of the treatment may be diminished gradually every day until it is no longer demanded. This is an especially efficacious method of dealing with the calcareous or chalky degeneration of accumulated Meibomian matters.—*Medical Herald*, March, 1883.

TANNATE OF CANNABINE.—By distillation with water Indian hemp yields an ethereal oil consisting of cannabine and cannabine hydrate. It is a golden-yellow liquid with a disagreeable odor and taste, and very poisonous. A small quantity when subcutaneously injected causes very great local irritation, and produces an inflammatory swelling similar to that of an immense abscess, the swelling being accompanied by a high degree of fever. The hydrate of cannabine is moreover easily decomposed and is therefore unfit for use in medicine. When combined with tannin it forms a stable compound which does not appear to possess any poisonous properties, but when given internally acts as an excellent hypnotic.

Dr. Fronmueller, of Fürth, has recently described in the *Zeitschrift fur Rati. Prackt. Aerzte*, 1882, p. 257, the results obtained from its use in the treatment of various diseases. He finds that it possesses the advantage over extract of Indian hemp of not passing through the intestines without being absorbed. He considers that it is also preferable to the extract on account of its more equal strength. He has remarked that the extract of Indian hemp now met with in commerce is much stronger than it used to be. Thirty years ago he found eight grains were required as a dose; twenty years ago four grains proved effectual, but two grains are now usually sufficient.

Dr. Fronmueller experimented with the tannate on 73 patients, 21 of whom were men and 42 women, and most of them had previously been tried with opiates, or with a subcutaneous injection of morphia. The doses given were usually 0.1 to 0.3 gramme, but in cases of maniacal insomnia as much as 1½ gramme was given. In no case was vomiting or constipation produced. It appeared to be especially useful in cases in which opium caused excitement, or in which it was desirable that an hypnotic should not cause constipation. Only in exceptional cases was any sign of intoxication produced.

A small quantity of alkali renders the tannate soluble in water.—*Midland Medical Miscellany*, February, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,
PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MARCH 17, 1883.

LEGAL PROTECTION OF THE INSANE.

THE time is ripe for legislation as to the insane. Some time since we commented on the utterly insufficient safeguards as to commitment of the alleged insane. We do not believe, as we have plainly said, that the Rev. Mr. Newton's views are correct. Few, very few of the sane, are ever confined in insane hospitals. To picture the horrors going on "behind the bars" will do for sensational novelists and sensational preachers, but the pictures are over-wrought, and rarely true. Yet we all want to make sure that they shall *never* be true. And further, if the lunatic becomes of sound mind, we want to be certain that liberty shall go hand-in-hand with restored mental capacity. Further than this the public perhaps do not go, but the profession do. They desire that the insane shall have thorough scientific investigation and treatment, and that post-mortem examinations and pathological studies shall add constantly to the sum total of our knowledge of psychiatry.

We are led to these reflections especially by a perusal of the report of the commission lately appointed by the Governor of Pennsylvania to investigate the existing lunacy laws, and to suggest improvements in them. Among the eminent gentlemen of the commission are such well-known medical men as Drs. S. Weir Mitchell, J. A. Reed, and J. T. Rothrock, names which in themselves are a guarantee that the bill which they propose is, in general outline at least, wise and proper. This bill is now before the Legislature, and we hope most earnestly that it will pass, with some amendments which we shall suggest, and which we regard as important.

It provides for a Lunacy Committee connected with the State Board of Charities, of which one member shall be a physician, and one a lawyer, each of at least ten years' practice. This Committee shall issue licenses to all hospitals for the insane, whether public or private, and with the Attorney-General and the Chief-Justice of the Supreme Court, make general regulations for their conduct. They shall appoint Boards of Visitors, of which women may be members, who with the Committee shall constantly inspect and investigate all such institutions, and at frequent stated intervals examine into the condition of the patients. After due notice to the hospital authorities and to the persons committing any alleged lunatic, they may discharge any such whom they believe to be improperly detained in custody. The physicians upon whose affidavit any person is so committed, whether to public or private insane hospitals, may not be graduates of yesterday, but must be practitioners of at least five years' standing, not related by blood or marriage to the lunatic, nor connected with the hospital to which he is to be committed. Correspondence is not only to be inviolate, but is to be stamped and forwarded daily, and any desired communication is to be written at dictation and forwarded, and any person whom the lunatic may desire to see is to be sent for. Case-books are to be kept for recording each case in proper detail. The criminal insane are also properly to be cared for.

It is also suggested, though not included in the bill, that the chronic and incurable insane shall be simply and cheaply cared for separately from those requiring active remedial measures, in economical small detached buildings connected with the larger hospitals; that convalescent wards be established to separate those returning to reason from the seriously insane; that employment by farm labor, teaching each other, and other modes of occupation shall be provided; and that restraint be but sparingly employed, if at all.

Our readers will see that this is a most excellent bill, and far in advance of our present imperfect and inadequate laws.

The objectionable features as we look at them are not many, and, in general, are of minor importance. In guarding the rights of the insane we must be careful not to trench upon the rights of their proper and necessary custodians. That provision which makes the medical attendant responsible for costs in cases of habeas corpus, unless the judge shall certify that there was sufficient ground to warrant the detention, is certainly objectionable. Insanity is a disease from which recovery is slow, and the exact period when reason is restored and competency to act for one's self returns, can only be fixed

with difficulty, and often after weeks of careful observation and repeated tests. To leave this question to the decision of a judge, a non-medical man, and perhaps prejudiced against the respondent on general grounds is unwise. If it must be so left, it should be put negatively, and more strongly, that he should certify that there was "clearly *no* sufficient ground for the detention."

Moreover, to empower a Committee of five, of whom only one is a medical man, to discharge any alleged lunatic is perilous. They should only do so on a favorable report from a board of competent alienists, whom they should be authorized to appoint for the investigation of every doubtful case.

Again, the medical officer is required to enter his opinion, *i. e.*, make a diagnosis, in his case-book, within twenty-four hours after the patient's admission. Surely a week would be none too long a time in many of the complicated cases. Sometimes they require even a much longer time and intimate study to furnish sufficient data for an exact diagnosis which may at any moment be made the subject of a legal inquisition. Snap diagnoses are most of all out of place here.

The family or other physician designated by the friends is allowed to prescribe for the patient for all other ailments than insanity—a dangerous privilege, involving many a possible conflict. That he should always be allowed to visit the patient and investigate his condition, is evidently just and right; but not to treat him. Nay, we would go further; with Clark Bell, we would give the lunatic or his friends the right at their own cost to have his mental condition investigated at any time by experts unconnected with the hospital.

One very good provision of the bill is that persons may sign away their liberty, and voluntarily enter an insane hospital and be kept under restraint. Many cases of drunkards and opium eaters could thus be satisfactorily treated. But the time allowed by the bill—seven days, with privilege of repeated renewals for a like period—is too short! Thirty days should be fixed as a maximum. Less than that will do but little good.

Finally, in the matter of correspondence there ought to be some surveillance, lest serious evil be done. Suppose that a young lady while insane writes an indecent letter, it may be to an indiscreet friend or to an enemy. The bill allows no discretion. The letter must be sent. After her recovery shall that letter ever stare her in the face, and compromise her good name? and shall the sane be daily annoyed by receiving voluminous and disturbing epistles? No letter should ever be retained or destroyed lest, under the guise of protection, the patient be wronged, but let the bill be amended after the English law. By it every letter must be forwarded to the person addressed, unless the Superintendent deems it an improper communication. If so, he endorses his opinion on the letter and it is forwarded to the Commissioners of Lunacy, who dispose of it properly.

CLIMATE IN THE TREATMENT OF CHRONIC ALBUMINURIA.

IN reply to the queries of our correspondent as to the relative advantages of a warm and dry climate, as compared with a warm and moist one, in the treatment of chronic albuminuria, we would state that the chief advantage of the former lies in the fact that in such a climate the surface of the body is less apt to be bathed with moisture than in the latter; consequently there is less danger from exposure to draughts of air, which always operate more seriously in chilling the body of which the surface is moist than that which is dry. It is well known that exhalation from the skin is greater in a dry atmosphere than in a moist one, although it is less apparent. In the latter, the perspiration becomes more sensible because its evaporation is less rapid. For these reasons we prefer a warm and dry to a warm and moist climate; although the latter is, of course, to be preferred to a cold climate.

It is of advantage, also, if such a climate include a section of country in which aperient mineral waters are natural. Hence it is, that southern Germany is so suitable, the waters of Marienbad, Franzenbad, Carlsbad, and Püllna fulfilling this indication. All of these places are in Bohemia, and within a short distance of Prague. Marienbad, beautifully situated two thousand feet above the level of the sea, probably fulfils the requirements best of all. In this country we know of no places which afford both of these advantages; but of warm and dry climates, that of southern California (Santa Barbara and Monterey), and the west or Gulf coast of Florida are recommended. For warm climates, regardless of dryness, the places of usual resort in Florida and the Gulf States generally, fulfil the indications. Mobile, Alabama, in consequence of the beauty of its situation, as well as several hamlets in its vicinity, and San Antonia, Texas, may be mentioned, as well as Aiken, South Carolina, and Augusta and Thomasville, Georgia. Nor should Bermuda be omitted, for although not in our own country, it is quite accessible, and its climate scarcely surpassed.

Our attention has recently been called to the climate of Sabinas Hidalgo, in the State of Nuevo Leon, in Mexico, one hundred and twenty miles from Laredo Texas, as peculiarly dry and equable. It is said to be easily reached by trains with sleeping cars from St. Louis *via* San Antonio to Laredo

and the Mexican National Railway. Doubtless the recently established railway communication with Mexico will open to us numerous other localities in which the elements of a dry and warm climate are furnished.

LATHYRISMUS.

As this term may be new to our readers, it is, probably, desirable to enter into some explanatory details. *Lathyrus* is a genus of leguminous plants, and *lathyrismus* is a condition of the system induced by the consumption of a bread composed, in part, of the flour of *Lathyrus cicera* (everlasting pea). As ergotism results from the long-continued consumption of ergotized rye, so lathyrismus is produced by the persistent use of a bread composed in part of a flour of lathyrus. Quite independently of its economic aspect, the use of a flour producing such effects, has an importance determined by the character of the attendant phenomena.

In 1873, lathyrismus was reported on by Prof. Cantani, after an investigation made of the disease as it appears in certain parts of Italy. It is not limited to Italy, however, since Bourlier, in 1882, described, in a clinical lecture, the same malady as it appeared in Algiers. Last year, also, Dr. Giorgieri, of Parma, gave an account of two new cases which had occurred under his observation. The accounts thus far published agree in the character of the nervous disturbances produced by this substance. The effects of lathyrus, or the condition called *lathyrismus*, correspond closely to the symptoms belonging to antero-lateral sclerosis. The same gait; the same spastic rigidity of the muscles; and the accompanying nervous disturbances characteristic of this disease, are reproduced in the affection caused by lathyrus. These results may be due to the presence of an alkaloid in lathyrus, or they may be the product of changes effected in the intestinal tube. The former view has no novelty, but the latter opens up a wide range of speculation, and is suggestive both from the physiological and from the chemical side. As from amygdalin and emulsin, both without toxic action, hydrocyanic acid, the most powerful of poisons is produced, so it is possible, under conditions not now comprehended, for other innocuous agents to become the means of generating morbific principles. In the acute infectious diseases, alkaloidal substances are formed in the intestinal canal, and in dead bodies ptomaines are elaborated. It may be, that under some circumstances, articles of food, in themselves harmless, become the agencies for the formation of disease-producing materials. In the search for an explanation of morbid actions occurring in the nervous system, such agencies should have due recognition, in the absence of more specific causes.

TEMPERATURE OF THE LIMB AFTER NERVE-STRETCHING.

M. Redard has ascertained, by the use of a thermo-electric apparatus, that in animals after elongation of the sciatic, the temperature of the limb operated on notably declines, and this reduction persists for two or three months. He also observed that the temperature on the sound side falls, but to a less extent and for a shorter time. Several conclusions may be deduced from these observations, if they are true as stated. M. Redard does not allude to any experiments of control. As a marked reduction of temperature takes place in certain animals—rabbits notably—by mere confinement and arrest of all muscular action, we need to know in respect to these experiments, what were the conditions of the animal during and subsequent to them, and whether any control observations were made?

If it be clearly established that by the stretching of a nerve such wide-spread effects follow, this operation can no longer be regarded as local. If, when the sciatic is stretched, the temperature of corresponding areas on the opposite side is distinctly affected, we cannot avoid the conclusion that the results of nerve-stretching include an impression on the trophic centres. We have in this result, then, an explanation of the influence exerted on locomotor ataxia by the operation of pulling on a sciatic nerve.

If Redard's experiment be supported by subsequent experience, Voit's opinion that the effects of nerve-stretching are local in result, will no longer be tenable, but the opposite view must then be maintained, that nerve-stretching affects the central nervous system.

Another conclusion to which these experiments conducts us is, that heat production is not wholly a chemical process, but is under the control of the nervous system. It would be absurd to state this as a novel view; nevertheless every fact conclusively showing this effect of nervous influence has importance. In respect to this, as the other point above discussed, we need to know how far Redard's observations were suitably controlled. Temperature is so decidedly a result of physiological activity of muscular tissue, that when it is affirmed that nerve-stretching affects the body-heat, we wish to know how far other conditions may have interfered in the results in this direction also.

VENTILATION OF SEWERS.

M. Wurtz, of Paris, has recently made a series of analytical tests with the object of determining the effects produced by the free admission of air into sewers, or, in other words, by thorough ventila-

tion. The results of these experiments are important, inasmuch as they reveal the fact that the free circulation of air in sewers acts beneficially, not only by diluting and dispersing sewer gases, but also by destroying them chemically.

Mr. Eassie has described the manner in which these changes take place in the sewers, as demonstrated by M. Wurtz. He says that when the motion of the waters renews the surfaces, bringing them incessantly in contact with oxygen, when there is a free current of air in the sewers, the sulphuretted hydrogen becomes readily oxidized, and inodorous, non-volatile sulphates of ammonia are formed. This reaction is rendered still more energetic by moisture, which is always present in the air of sewers and is deposited by the condensation of steam against the brickwork and the walls of the water-mains, as well as of all the other pipes which are placed inside the Paris sewers. These large humid surfaces hold in a state of solution such portions of the highly soluble gases as may not have undergone a chemical change, and thereby prevent their expulsion into the outer air. On the other hand, however, when the ingress of air into the sewers was stopped; when the water, on becoming stagnant, discontinued the process of multiplying its surfaces of contact with the oxygen; not only did the sulphuretted hydrogen cease taking up oxygen to transform itself into sulphates, but the sulphates themselves, which had previously been formed, would be resolved by the organic matter in course of decomposition. This organic matter, depriving the sulphates of their oxygen, would reduce them to sulphites or sulphuretted hydrogen, and then would follow a black settlement, an evolution of bubbles, and layers of slimy froth.

As to the effect of free ventilation upon the minute morbific organisms which are supposed to infest sewer-air, and which all efforts have thus far failed to isolate, little can be said from the standpoint of experimental knowledge: but it seems reasonable to believe that these subtle organic elements, as well as the gaseous constituents of sewer-air, are oxidized in part and dispersed by the free admission of atmospheric air; and that there is less chance for their development, concentration, and transportation into the apartments of our dwellings, through the channels of sewer connections, under the conditions of free ventilation above mentioned, than when the sewers are trapped and hermetically sealed, and direct communication with the outer air is, in this manner, prevented.

THE RIGHT TO MAKE AUTOPSIES IN HOSPITALS.

LAST year a case was decided in England which is of special interest to hospital staffs, as it involved the question of the right of a doctor to make an autopsy. A post-mortem examination had been made on the body of a child dying in hospital, but no previous communication was made to the relatives, nor was their consent asked or obtained. The medical man was charged with improper mutilation of the body. The magistrate, after a week's deliberation, ruled that the Anatomy Act did not apply, and that the surgeon would not be liable to indictment unless it could be shown that the examination had been conducted in such a way as to offer an indignity to the body.

We are not aware that a legal decision has been given in any similar case in this country. It is, however, such an important point, especially in hospitals, that we should be glad to know that our American courts held the same view as the English. Gratuitous services, often very prolonged and requiring great skill, are but poorly requited when the medical man is allowed at least to learn all he can from such a case. Yet we have known the right to be often denied, and hospital authorities are so afraid of criticism, that they not seldom join with the relatives in refusing to allow such an examination.

COLLEGE GYMNASIUMS.

No one who has visited the magnificent gymnasium of Harvard, will hesitate to listen to anything that Dr. D. A. Sargent, its director, has to say as to physical education in colleges; and no one will rise from reading his article in the February number of the *North American Review*, without approval of his views, founded, as they are, on reason and common sense.

Some facts that he gives surprise us. The maximum of time for physical education required in the best of our colleges is but four half hours a week, and that for only a small part of the year. At Harvard, Princeton, Yale, and Cornell, less than five per cent. of the students are rowing men. Not over ten per cent. of college students pay any attention to physical education, and less than six per cent. do it systematically. That their development is lop-sided is no wonder, the athletes running chiefly to muscle, and the scholars to mind. Each alike forgets that a symmetrical development of both is necessary to make the complete man, *totus et teres*, if not also *rotundus*. The remedy Dr. Sargent proposes is simple, sensible, and efficient. It is first, a good gymnasium; second, that physical exercise shall be a required study throughout the course; and thirdly, that there be an instructor, who ought to be a college graduate, a gymnast, and a doctor. He should have competent authority in his department, adapt the exercise, both in kind and degree, to the individual student, and keep systematic records of the progress of each

student. Those who know the value of the "Sargent System" will appreciate what immense service such a course would do to the physically neglected young men in our colleges. We commend the paper to the thoughtful consideration of college authorities, with the hope that its suggestions may be adopted, not only in men's colleges, but in women's, in which it is needed even more.

THE NEW ANATOMY ACT.

The new Anatomy Act has passed the Pennsylvania State Senate, and has gone to the House with two seriously damaging amendments.

The first is that, in addition to relatives, "any person" may claim the body for interment. This is a direct encouragement to "body-snatching." It is clear that medical schools *must* have subjects for dissection, or else close their doors and let the education of physicians, so far as they are concerned, cease. Under this amendment what is to hinder "any person" from claiming *every* dead pauper or criminal, ostensibly for interment, but really for the use of the medical schools? What is to hinder them from effecting a pretended or a real burial on private property, to be followed by a disinterment and sale —a sale always guarded under the euphemism that the charge, exorbitant though it be, is only for "transportation"! And again, what is to be done if two or three such persons claim the same body?

The other amendment very properly provides that the medical men of each county shall have prior right to the unclaimed dead of their own county, but adds that the bodies shall be held subject to this claim for a period of *ten days*. This completely defeats the objects of the bill so far as it is intended to relieve the pressing needs of the medical schools of the State. To carry out this clause would necessitate each almshouse, morgue, and prison to provide means for their preservation from decomposition — a practical impossibility. Even in winter, unless so preserved, every body would decompose in less than ten days, and in summer two or three would be enough to render them useless.

We hope that the physicians throughout the State, recognizing the unreasonableness of these amendments, will at once use their personal influence to secure their defeat in the House. The medical schools of the State, while desirous of increasing their own facilities for teaching, are also anxious, as the original bill shows, *to aid the profession throughout the State* in securing material for practical study in anatomy and surgery, a privilege the present law denies to them. In return, a hearty support should be rendered to the just claims of the medical schools of the State—a support which we have no doubt will be cordially given, now that the provisions of the bill are properly understood.

REVIEWS.

A System of Human Anatomy, Including its Medical and Surgical Relations. By Harrison Allen, M.D. Section III.—Muscles and Fasciæ. 4to. pp. 243 to 334. Philadelphia: H. C. Lea's Son & Co., 1883.

This admirable work goes on steadily to completion. The praiseworthy features we have already pointed out in our notice of Sections I. and II., are as noticeable in this. The anatomical descriptions are, in general, models of brief but sufficient statements. Both student and practitioner will find the text free from the elaborate and minute descriptions which, while important and proper in a descriptive anatomy, properly so called, would be out of place in a work intended to deal so largely with the clinical relations of anatomical facts. The literature of the profession has been thoroughly searched for cases illustrative of the applications of anatomy to medicine. We find perhaps fewer references to comparative anatomy than the previous well-known studies of the author would lead us to expect, but those that are introduced are to the point.

Having expressed heartily our high opinion of the work, we beg also to submit a few points of dissent, and to indicate some needful corrections. The plates are, in general, improvements over those of the previous sections, but have a certain rawness or harshness about them which we regret, and they are not wholly free from errors. Thus pl. xliii. has the lev. ang. *oris* as lev. ang. *superioris*. Pl. xlviii. has the extensor *indicus*. In neither this nor the preceding plate is there any good representation of the flexor sublimis digitorum, and in no plate a satisfactory one of the palmar fascia. In pl. xliii. and in the systematic list of the oral muscles appears the lev. lab. infer., as well as the mentalis, but in the text no description is given of the former, and in the plates the latter is nowhere shown. On p. 305 Dr. Buck's name is misspelled as Gordon, instead of Gurdon, and on p. 306 the foot-note numbers are wrong. As to omissions in the text, we note that the function of the omo-hyoid is not stated, and that the muscles of the perineum of the male only are given. The muscles of the female perineum, as also those of the larynx, will be given, we presume, in later sections. The superior and inferior recti, it is stated, roll the eye-ball upwards and downwards, no reference being made to their inversion of the ball, due to the angle between the axis of the ball and that of the muscles. So, too, dislocation of the patella outwards is ascribed to the superior strength of the vastus externus, no mention being made of the effect of the obtuse angle of the bones at the knee. The statements as to the functions of the extensor communis digitorum and of the interossei are to our mind not at all satisfactory. Rising from the reading of their functions, one would not have a clear, sharp-cut notion that the interossei flex the first phalanges and extend the last two (as was shown long before Duchenne by John Hunter in 1777), and that the extensor communis extended chiefly the first phalanges and only partially the second and third. Indeed it is stated that the extensor "extends the fingers, notably the third phalanges on the second, and aids in the lateral motions of the fingers," which are clearly errors, as any one may prove by faradizing the muscles.

We point out the errors and omissions so that they may be amended in a second edition, and not in any

sense in depreciatory criticism, for the work is a most valuable addition to our literature; creditable alike to its author and his subject. It cannot fail to be of service to every reader.

SOCIETY PROCEEDINGS.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Stated Meeting March 7, 1883.

EDWARD HARTSORNE, M.D., IN THE CHAIR.

DR. WALTER F. ATLEE read the following

HISTORY OF A CASE OF ABDOMINAL CYSTIC TUMOR, WHERE SEVEN YEARS AFTER REMOVAL OF THE TUMOR BY LAPAROTOMY A SECOND OPERATION WAS DEMANDED: TAPPING THROUGH THE VAGINA RESORTED TO, WITH CONSEQUENT DEATH OF THE PATIENT.

In June, 1875, I removed, by laparotomy, in the St. Luke Hospital, Bethlehem, a multilocular cyst from Mrs. DeM. The history of the case was given by Dr. Stout to the Board of Trustees, and published in their second Annual Report. The whole mass removed at the operation weighed seventy-eight and a half pounds. The lobes and lobules composing it were made up of cysts containing fluids of different densities, colors, and other physical properties. The pedicle appeared to arise from the rectum, at all events, the cyst-wall was separated from everything else, except the front of that intestine, and the only ligature used was there applied. The whole vascular supply was derived from meso-rectal vessels. Of course, the clamp could not be used. As always, in sewing up the incision in the abdominal walls, I carefully included the peritoneum in the sutures, as in this way adhesions of intestine and omentum, with the consequent discomfort and constipation suffered by the patient, are never observed, and, moreover, in case a second ovariotomy should have to be performed, the operation could be performed with much more ease and safety.

This patient recovered from the operation, though somewhat slowly, owing to delay and difficulty in removing the ligature, which was left hanging out of the external wound, and not cut short and left inside the abdomen, as is now generally practised. She remained in perfect health for seven years, but in the summer of 1882 came to my office complaining of considerable discomfort in the pelvis, where I detected by the touch, the presence of a swelling, caused by a thick, viscid fluid; in other words, there was plainly a second tumor formed there. This continued to enlarge, and in the month of January, the suffering it occasioned was so immediately threatening to the patient's life, that it was necessary to act. Great efforts were made to push the tumor out of the pelvis, but this was not to be accomplished. It remained to operate as before, and remove the mass by laparotomy, or to give relief by emptying the cyst by tapping through the vagina. The latter procedure was preferred, and about three pints of a very thick, dark-colored fluid were drawn off by a Thompson trocar. There was no difficulty about the operation, nor was it attended by any particular pain, nor was there any hemorrhage. The next day the patient felt herself completely relieved, but after that her pulse became quickened, and a general febrile condition, unpreceded by chill, succeeded. There was evident tenderness on pressure over the lower part of the abdomen, but no severe pain independent of this pressure. The stomach became so irritable as to reject everything swallowed. Death took place on the eighth day, under the marked symptoms of depression which accompany pyæmia. It was a death, most plainly, from cyst inflammation.

Notwithstanding the great number of cases of operation for ovarian disease reported nowadays in journals, more or less medical, this case is really one deserving of record, and one of true and special interest to the pathologist and to the surgeon.

In removing the large mass in the first operation, in this case, it was noticed that no pedicle was found. It was separable by the fingers everywhere except from the front of the rectum, where it was necessary to apply a ligature and divide the attachment by scissors. The ovaries, as we all know, are situated in the posterior fold of the broad ligaments, on the sides of the highest part of the uterus, behind the Fallopian tubes and the round ligaments, which separate them from the bladder, and in front of the rectum, from which they are commonly separated by the lowest circumvolutions of the ileum. By a rounded cord, the ligament of the ovary, they are attached internally to the womb, and externally by two folds of the peritoneum to the sides of the pelvis.

As the ovary, in its normal condition, is not pediculated, at first, of course, a diseased ovary has no true pedicle. As it becomes larger, this pedicle is formed from changes in its normal connections with the adjacent womb; it consists of the Fallopian tube often much elongated, the broad ligament often considerably thickened, the utero-ovarian ligament occasionally hypertrophied to a large fibroid stem, the round ligament, and enlarged bloodvessels. If the tumor rises out of the pelvis the pedicle will be longer, and if bound down in the pelvis from early adhesions it will be shorter.

In some cases, however, and they are by no means rare ones, when cystic tumors are removed from the abdominal cavity, no such pedicle as the one just described is met with. In the case, whose history I have been relating, it was said that there was no distinct pedicle, and that the whole vascular supply came from the vessels of the meso-rectum. It may naturally be supposed that this was owing to the way in which the diseased mass may have been separated from its surroundings, and I therefore call attention to the fact that the same thing has occurred in the practice of an operator such as Spencer Wells. In his *Diseases of the Ovaries*, in relating Case CX., he says that he found no pedicle, and that the tumor derived its vascular supply from the omental and mesenteric vessels.

It seems to me most reasonable to look upon some of the abdominal tumors having these connections, not as enlarged and diseased ovaries, but as changed ovules, which have failed to enter the Fallopian tubes, have slipped in the interstices of the neighboring organs, become attached, received blood, and grown. In women, when the Fallopian tube has become adherent, in place of floating loosely, the ovule is not grasped as it leaves the ovary, and then it is not rare to see ten, fifteen, twenty, or even more small cysts, some as large as a pea, on the parts immediately in contact with the ovary. (See Sappey, vol. iii., p. 664.)

If one of these misplaced ovules was attached to a spot where plenty of blood was supplied, a large cyst could be formed, having no distinct pedicle, as in the case before us. As is seen in cases of extra-uterine fœtation, a well-made child can be formed in this way from a fecundated ovule, and we may suppose that from an unfecundated one a monstrous polycystic growth should form.

Although out of the way, I wish to mention here that the only two cases in which I have been consulted on account of a return of abdominal cystic tumors, were where there was no pedicle, and where the chief vascular supply came from the vessels in

front of the rectum. One case is the one now under consideration, and the other is the one published in the *American Journal of the Medical Sciences* for January, 1883, on account of the bladder having been opened during the operation.

My reason for reporting this case, however, is not to advance any particular views in regard to the pathology of certain polycystic tumors of the abdominal cavity, but in order to speak of the mistake made in the treatment. In the words of one who has done as much as any other to advance our knowledge of the treatment of abdominal tumors, "Mistakes teach most valuable lessons, and, when discovered, are not likely to be repeated. Hence, in medicine, they should be recorded for the benefit of science and of humanity." (*General and Differential Diagnosis of Ovarian Tumors*, by Washington L. Atlee, in preface.) When this case presented itself, it was necessary to act; a speedy and most painful death was inevitable unless relief were afforded. It remained to choose between the removal of the cyst and the emptying of its contents by tapping through the vagina, the only way practicable of introducing a trocar. On account of the operation previously performed, and the impossibility of moving the mass in the pelvis, its removal was not attempted. A previous operation is not necessarily an objection; Dr. Washington L. Atlee records two cases where a second operation was performed, and in both successfully. Spencer Wells, in his table, gives thirteen cases in which he removed an abdominal tumor from a patient who had previously undergone the operation, and eleven of them were successful. Here, however, the immovability of the tumor was such as to make me positively sure that the attachments were so great as to render its removal impossible.

Of tapping through the vagina I had no personal experience whatever, and what is recorded by others, although not, as a general rule, favorable to the plan, did not deter me from it. Scanzoni goes so far as to say that if puncture by the vagina was always possible, abdominal puncture would soon completely disappear from surgical practice. The sac, opened in its lowest part, can empty itself more completely. (Scanzoni, *Traité pratique des Maladies des Organes sexuels de la Femme*, Paris, 1858.) Peaslee says that there are three considerations to deter us from it in all ordinary circumstances: 1st. The vessels are larger and more numerous at the lowest part of the tumor. 2d. If polycystic, the largest cysts are not at its lowest part; and 3d. There is greater risk of wounding other organs. (Peaslee, *Ovarian Tumors, their Pathology, Diagnosis, and Treatment, especially by Ovariotomy*, 1872.)

Emmet writes that he has punctured several cysts with a trocar from the vagina, and in every instance more or less cellulitis has resulted. This might, however, destroy the cysts, but he is not able to determine that, for all the cases passed from under his observation. (Emmet, *Principles and Practice of Gynæcology*, 1880.)

Thomas says that by this method two of the dangers of tapping, secondary escape of fluid into the peritoneum, and consequent peritonitis, are unquestionably avoided, but others are as surely increased, namely, those of injury to portions of the intestine and entrance of air into the sac, with consequent decomposition of the contents, septicæmia, and inflammation of the sac walls. His experience with the method is not large, but it leads him to agree with Spencer Wells. (Thomas, *Diseases of Women*, 1872.)

Spencer Wells says that tapping through the vagina is more liable to be followed by inflammation of the cyst than tapping through the abdominal wall, because it is not easy to prevent the entrance of air. The operation of tapping through the vagina is selected, not so much with the intention of simply emptying the cyst, as for the chance that should the fluid escape by the opening, as fast as it is secreted, the cyst may gradually contract, and the puncture close. This favorable result, however, is seldom secured. As a rule, air enters the cyst, the opening fills up, the fluid remaining in the cyst, or that newly secreted putrefies. Suppurative inflammation of the lining membrane of the cyst comes on, and is accompanied by a low form of septic fever or pyæmia, which can only be relieved by making and maintaining a free outlet for the discharge. The frequency of these consequences should make tapping by the vagina an exceptional practice, but it may be adopted in cases where an ovarian cyst is bound down in the pelvis by adhesions, and it is necessary to relieve the distress caused by pressure on the bladder and rectum.

The canula or an elastic catheter may be left in the cyst, though it is safer practice either to introduce a wire seton or a drainage-tube, so as to prevent the opening from closing, and make sure of the free and immediate escape of any fluid that may be secreted. Even with every care, however, Mr. Wells concludes, from his experience, that patients are so apt to suffer from some of the ill-effects of long-continued suppurative processes, that it is better, even at considerable risk, to remove a cyst, if at all possible, than to trust to any mode of drainage. (Spencer Wells, *On Ovarian and Uterine Tumors, their Diagnosis and Treatment*, 1882.)

Dr. Charles West, whose opinions have for me, at least, extraordinary importance, greater indeed on such a point than those of any other man, says that there is no doubt that inflammation attacking parts within the pelvic cavity is less apt to extend to the peritoneum than when it attacks an abdominal organ; of which rule pelvic cellulitis and inflammation of parts within the folds of the broad ligaments are apt illustrations. It is equally incontestable that pelvic peritonitis is less apt to become generalized than is similar mischief originating in the abdomen. Cyst inflammation is so dangerous, however, that it is doubtful if vaginal tapping may be employed, even when the cyst is simple. Its dangers are incalculable. The dangers of ovariotomy are far less. Except when a cyst is impacted in the pelvic cavity, he does not recommend tapping per vaginam. (West, *Lectures on Diseases of Women*, 1879.)

Our best authorities, therefore, teach us that the taping of polycystic tumors, at least, must be avoided; that the removal of the cyst is to be practised in preference; that when impacted in the pelvis, so that it interferes with the performance of functions absolutely necessary to life, tapping, to which we must have recourse, is particularly dangerous, owing to the frequency of cystic inflammation, and consequent death from septicæmia. In my case I thought to avoid this by taking precautions to hinder the entrance of air into the cyst, but it took place notwithstanding, and the death of the patient was occasioned by it in eight days.

If, unhappily, I should ever again be called upon to try to relieve a similar case, I should act differently, and, not relying upon any means to prevent the setting up of cystic inflammation, do more to establish a free outlet for the noxious products by which the system is poisoned, and do everything in my power to prevent their formation, by topical applications to the secreting surfaces of the cyst.

Dr. Noeggerath (*Ovariocentesis Vaginalis*, *American Journal of Obstetrics*, May, 1869), by pursuing this course, had such good results as to declare himself confident that, where a simple or compound cyst could be attacked through the posterior vaginal cul-de-sac,

this operation would take the place of laparotomy. The plan he prefers is to make first a transverse incision, about an inch long, behind the cervix uteri and through the roof of the vagina up to the cyst. This, coming into view, is then evacuated by a free incision, and, finally, the edges of the two incisions are stitched together by five or six silver sutures. The cyst thus left free and permanently open is daily washed out with antiseptic injections until it finally contracts, and ceases to afford any secretion. Although, at the present time, it is not likely that in ordinary cases any one would choose to perform this operation to that of the removal of the cyst, yet all experience shows that when the cyst is so firmly fixed in the pelvis as not to be removable, it diminishes in a marked degree the great danger necessarily incurred by tapping through the vagina—that of poisoning of the system by the absorption of the putrid products of cystic inflammation.

I feel certain myself that I made a sad mistake in not operating in this way, and report this case, as a warning to others—*Bene faeit qui ex erroribus aliorum, sibi exemplum sumat.*

DR. WILLIAM GOODELL said that he did not think the attachment of the tumor to the rectum was so unique as the return of the tumor. He had on several occasions removed tumors without being able to find the true pedicle, on account of the many adhesions. He could not agree with Dr. Atlee with regard to the origin of the cyst—he did not think it could have come from a wandering ovum, since, in that case, it would have been monocystic.

He regarded tapping per vaginam hazardous, for the reasons given by the late Dr. Peaslee, first, on account of the danger of wounding bloodvessels, and second, on account of the danger arising from the entrance of air into the cyst. He did not understand why the air could enter the cyst so readily after tapping per vaginam. When he performed tapping by this method he employed the aspirator. Returning to the question of the attachment apparently of the pedicle to the rectum, in the case reported, he said that it was quite common not to find a pedicle in some forms of intra-ligamentous cyst, because they had to be enucleated, and referred to the statements of Lawson Tait with regard to this difficulty of determining the origin of the tumor. He desired to call attention to the pathological characters of the recurrent growths, and stated that according to his observation they were always malignant, and that they recur in the stump of the pedicle, or, as he had seen, at the site of the adhesions. He alluded to a case which occurred in his own practice, and to one related to him by Dr. Bantock, of London, which confirmed the statements made.

He asked Dr. Atlee whether he could explain why the air entered so readily into cysts after tapping per vaginam.

DR. ATLEE in reply said that he had seen no reason given, but thought it was owing to the difficulty in closing the wound made in the tapping.

DR. R. P. HARRIS remarked, that perhaps he could throw some light upon the cause of this admission of air, from what he had observed in a case of removal of hemorrhoids. Some years ago, soon after the introduction of the écraseur of Chassaignac, he called in the late Dr. Joseph Pancoast, who had obtained the instrument, to make use of it in removing a mass of hemorrhoids from the rectum of a very anæmic man, rendered such by repeated hemorrhages after defecation. After the operation, to prevent, as he stated, the suction power of the diaphragm upon the rectum, endangering secondary hemorrhage, Dr. Pancoast introduced into the anus a small box-wood tube. The effect of this was soon demonstrated: a large drop of serous fluid descended the tube and stopped at its exit; when the diaphragm arose in expiration, the drop was drawn up the tube, and when it descended in inspiration, it came down again; thus showing the pumping effect of the diaphragm upon the pelvic contents. Let this open tube become an opened cyst with flaccid walls, and we have air pumped into the cyst, as it was into the rectum of our patient.

DR. J. EWING MEARS asked Dr. Atlee whether a post-mortem examination had been made. He thought the observations of Dr. Goodell with regard to the difficulty of finding the true pedicle in cysts with many adhesions, and to the pathological characters of the recurring tumor in these cases to be correct, as such had been his experience in instances of which he had had personal knowledge. With regard to the entrance of air into the cyst, when tapping is performed per vaginam, he thought the explanations of Drs. Atlee and Harris were correct. A cyst firmly impacted in the pelvis is separated from the vaginal tube by a comparatively thin septum, differing greatly in its anatomical characters from the abdominal wall. The opening made by the trocar in this septum and in the cyst wall attached to it by adhesions, does not close perfectly, and the air drawn up into the vaginal tube passes readily into the collapsed cyst.

DR. ATLEE, in reply to Dr. Mears, stated that no post-mortem examination had been made.

CINCINNATI ACADEMY OF MEDICINE.

Stated Meeting, February 15, 1883.

THE PRESIDENT, J. S. CLEVELAND, M.D., IN THE CHAIR.

DR. GEO. E. WALTON, having recently returned from an extensive tour in and about Florida, read a paper on

THE THERAPEUTIC VALUE OF THE CLIMATE OF FLORIDA.

DR. WHITTAKER observed that the opinions of the essayist were certainly entitled to great credit, because he had made something of a specialty of balneology and climatology, and had based his statements upon personal observations. He believed, however, that all our knowledge of climatology stands in need of revision, to make it correspond with the recent disclosures concerning the etiology, or pathology, of infectious diseases, which are the affections to which we chiefly have reference when we speak of the influence of climate; for up to the present time climatology has been construed chiefly to refer to miasmatic influences, as determined by heat, moisture, and vegetable decomposition, together with some definite knowledge concerning atmospheric vicissitudes, and some vague allusions to electric conditions; and all these facts were considered rather in the light of producing and engendering the poisons of disease. But the present tendency of etiology is not to admit the possibility of producing infectious diseases by any such causes, but to maintain for each an exclusively parental birth; so that the factors which go to make up a climate should be studied from the standpoint of disseminating rather than developing a disease; just as we would say that a high wind would spread, but could not produce, a fire.

We do certainly recognize every day the interdependence of disease and climate. Thus the tropics have been, from time immemorial, hot-beds of cholera, dysentery, and yellow fever; while the temperate regions are the home of malaria, rheumatism, bronchitis, etc. The arctic zone enjoys comparative immunity from infections, and in the extreme regions of the north the process of "taking cold" is almost unknown, and would be so entirely, perhaps, if its inhabitants could

entirely dispense with indoor life. Surgeons tell us that wounds heal much more kindly and quickly in the arctic regions, or what is the same thing, at high altitudes elsewhere, than in the temperate or torrid zones, or in the lowlands. Moreover, we may actually draw a line beyond which some diseases do not pass at all. We know the limits of yellow fever and malaria, and beyond the fortieth degree of latitude, it is said, that though sporadic cases may occur, dysentery almost never becomes epidemic.

We know pretty well as the sum and substance of the study of many centuries, what are the conditions that favor the spread of disease, but what we want to know now, is the nature or cause of the disease itself. We are a good deal like a farmer who understands pretty well the condition of his soil, but is ignorant of the character of his seed.

Now, however, that we are being furnished with definite information regarding the germs of disease, we can begin to see definitely how they are affected by climates. Recent researches in physics have revealed the fact that the air everywhere is full of germs, and we make unconscious studies of them every time a ray of sunlight enters a darkened room. We live at the bottom of a vast aerial sea, thickly peopled with dead and living things. Mr. Tyndall has shown us that the color of the sky is due to these atmospheric particles, and that the sky is literally the dust of the earth. All these particles, animate and inanimate, being material things, must obey the law of gravity, of course, and sink or float according to their weight. Like the stars, which are the motes of the universe, they circulate at different distances; but unlike them, they are more liable to be disturbed and carried away. Most germs are so heavy that they float near the earth, and would come to rest upon its surface if it were not for the wind which may waft them to great distances, and which, even when apparently still, moves at the rate of twenty inches per minute. The rain beats them down upon the surface of the earth, where they adhere for a time, and a strong wind blows them away, and so clears the air, as we feel and say, especially after a storm. But falling upon the earth, they adhere to its surface until again dried and dissipated by the sun and wind. Mr. Tyndall has shown us that the dust which falls in closed rooms is chiefly that which is deposited from the air in the room, and by coating the inside of a hermetically sealed box with glycerine to get a sticky surface, the beam of an electric light transmitted through its glass windows, visible before, becomes optically free from particles, and hence invisible in the course of a few days. Invisible, that is, it is dark like the regions of interstellar space. Of course, the bulk of the dust of the air is not made up of the germs of disease. Coal dust, mineral dust of various kinds, fragments of cotton and wool, pollen of plants, scales from the whole insect world compose a part of it; but the bulk of it is made up of germs infinitely minute, and infinitely more numerous than these particles. The common bacteria of putrefaction enter largely into its composition, as we soon find when we leave exposed to the air any organic matter. These germs seem to circulate in clouds, or we might say flocks, as we observe when a number of test-tubes containing organic matter is exposed to the air, that they are not all affected at the same time, or alike. When disease appears in a country, or a part of a country, we see the same thing in its attack of certain regions or individuals, and escape of others.

Heat favors the development of germs of all kinds, because all living things require a certain amount of it as an indispensible necessity of life. But different germs thrive under different degrees of heat. Thus the germs of milzbrand grow best in the cold climate of Siberia, while the parasites of tuberculosis require a body heat to develop and reproduce themselves.

Desiccation prevents or retards the growth of germs, and it makes a good deal of difference whether we inhale or ingest germs in a moist or dry state. Probably the exceptionally long stage of incubation we sometimes notice depends upon the relative dryness or humidity of the germs, and probably the immunity from disease of certain regions may be explained by the great dryness of the air. The weight of the air acts in the same way. A wet air is always heavy, and holds germs down near the ground, while a dry air permits them to float up above our heads. The health of altitudes is best explained in this way.

The germs of hay fever are very light; they float at great altitudes to great distances, but they permeate the whole air at times, and are often beaten down upon our streets by a heavy rain in a so-called "shower of sulphur." Numerous observers have now shown us how the prevalence and severity of hay fever stands in exact relation to the number of pollen grains that may be gathered upon a square inch of a gelatine-coated glass slide held in the air.

That heavy particles may be carried great distances by the wind is shown by the statement of Mr. Darwin, who remarks in his *Voyage in the Beagle*, that ships at sea have often been compelled to put about at distances of one thousand to sixteen hundred miles from shore by darkening clouds of dust which, on examination under the microscope, are found to consist of particles of sand or silicious matter.

Vegetable decomposition favors the development of germs of all kinds, perhaps by feeding them. Swamps and jungles have always been hot-beds of disease.

Florida, like all other tropical climates, offers thus all the factors for the spread of germs, and if Florida has hitherto had immunity from tuberculosis, it is because the disease has been only comparatively lately carried there. The soil has been fallow, but the seed has not been sown. Now that it is carried there, under the mistaken idea of curative resort, we will probably soon have mortality statistics equal to any of the States. Of course, the manufacturing towns will always excel Florida in this respect, because the bacillus tuberculosis is strictly a parasitic disease, and never develops spores outside the body. Hence, the accumulation of individuals in shut-up chambers or shops, as in factories, heated at that, offers the very best conditions for the spread of the disease. The relief which some patients do get in Florida during favorable seasons is due to the fact that they spend most of the time out-doors. The far greater immunity of Nassau, which, in the speaker's opinion, is the best place of resort on this hemisphere, is probably due to the constantly ascending column of heated air from its surface; sea-air is always healthy anyhow, because it is so little infected with germs, and many persons are cured or relieved of consumption at sea, provided they remain on deck. Under these conditions, as at Colorado, patients are protected against reinfection, or auto-infection, which is constantly taking place at home. For the actual number of germs in the body has much to do with the localization or generalization of the process. This fact has been abundantly proved by injections into the eye. A small number of bacilli injected into the aqueous humor produces a local tuberculosis, which only slowly and after a very long time becomes general, while a large number injected produces general tuberculosis in a few weeks.

The speaker had long ago found, as the result of his clinical experience, that Florida was the worst kind of a place for tuberculous patients, and he believed that the recent disclosures concerning the nature of the disease gave us a scientific reason for it.

As to other diseases, those which require an equable warm climate, like chronic or senile bronchitis, bronchiectasis, emphysema, etc.; those which call for appeal to the skin, like Bright's disease; those which call for relaxation and rest, like nervous diseases—Florida is the climate above all others. Jaded business men and overworked and worried professional men get the greatest relief in Florida, which is a typical "land of the lotus eaters."

DR. P. S. CONNER said that he was glad that the essayist sounded a note of alarm for tuberculosis in Florida. Before the war it was said to be the graveyard of consumptives. A great mistake is made in sending patients too far north in this State, where malaria is prevalent and where the temperature, though not frosty, is subject to too many changes. The southern coast is far more favorable; the air is more pleasant and vegetation is not near so rank and abundant as in the northern portion. For consumptives the southern part of Texas, New Mexico, and old Mexico are better suited than Florida. If the speaker were subject to phthisis, he would go south somewhere where there is little vegetation, as below the Keys of Florida, but he would spend most of his time on ship away from the land in the southern waters. He agreed with the previous speaker that Nassau and the other islands were preferable to the mainland of Florida. It is a question if it will ever be possible to establish sanataria in Florida. The climate of this State has been overrated. The trouble is, that by making it a place of resort for the sick it has become the place for hotel-keepers, doctors, and others who expect to live on the patients, and who trumpet forth this climate for the purpose of attracting as many patients as possible. In the speaker's opinion, Georgia and the southwestern coast was much better for consumptives than the southeastern coast of the United States. As regards winter climes, the speaker thought it very questionable if it would be proper to send all consumptives north. Minnesota may be very good for some persons but very bad for others. The same may be said of the other western health resorts.

DR. REAMY also congratulated the essayist on the pleasing and practical manner of dealing with his subject, a matter to which medical writers paid too little attention, generally.

He agreed to what had been said about the value of the climate of Florida for consumption, and, as far as his experience went, also confirmed what was said about the preference of Nassau and the Bahama Islands. A friend of his, Dr. Jackson, who was subject to phthisis, when so feeble that he could scarcely walk about, improved steadily as long as he remained in Nassau, but lost all his strength when he went to Gainesville, in Florida, whence he came home to die.

The speaker said he must, however, note one inconsistency in the remarks made by Dr. Whittaker. If an emigration of consumptives to Florida would make it a great centre for the spread of this disease, it is singular that in Nassau not a single native ever had phthisis. If the disease were so dangerous, in an island as small as Nassau all the inhabitants would soon have contracted it. If the conditions here are not so favorable for the development of bacteria, they are not such as to entirely kill them.

DR. WALTON said he was glad to find that all of the speakers agreed with him as regards the value of the Florida climate. He thinks in the future there may some place be found in Colorado or Arizona, sheltered on the northward by mountain ranges, which is dry, mild, and equable in climate, and specially fitted for consumptives; but as yet the necessary facts have not been obtained for selecting such health stations.

It is possible that tuberculosis depends on a bacillus, but we can hardly yet say whether this germ has actually been discovered. We are not yet in a position to say that taking cold has no causative relation to consumption; if none other, it may be that the depression of the system caused thereby, and the congested condition of the minute bronchial tubes, supply a favorable soil for the germination of bacilli. If catching a cold has nothing to do with the development of phthisis, it is difficult to understand why we see so much less of the disease in the warm air of a tropical climate. Statistics show that consumption is less frequent in the southern than in the northern States.

As regards Nassau, the speaker knew nothing more than that the mean average temperature is much higher than in Florida. Possibly the climate is drier from the evaporation caused by the heat of the sun, thus carrying rapidly upward all moisture from the surrounding ocean. If desiccated air prevents the development of bacteria, that may be the cause of the great improvement in phthisical patients.

One other factor in climate is perhaps of great importance, though it has as yet not been properly investigated, and that is the electrical condition of the air. It is well known that the upper region of the air is positive and the lower negative; that consequently we move continually in a negative plane of electricity. An instrument to record these electrical conditions would be a great desideratum in the United States Signal Service, if it were not too expensive. Such an instrument, but a very expensive one, has been used at Glasgow and London. It has been found that there are wide fluctuations in electrical potential, both positive and negative. It may be, therefore, that in Florida the mean electrical potential is low, thereby causing the relaxing influence of that climate. In order to accurately fix the climate of any place, several factors, as the humidity, ozone, and electrical potential, as well as temperature and rain-fall, must first be investigated, and all of these data have not as yet been secured for a single station in this country.

CORRESPONDENCE.

ON THE RESPONSIBILITY OF PHYSICIANS EMPLOYED BY MANUFACTURING PHARMACISTS.

To the Editor of THE MEDICAL NEWS.

SIR: It is the habit of trade rivals to seek the injury of their competitors by saying with regard to experts in their employ that they are "owned" by the house employing them, and that any opinion uttered by them is but the word put in their mouth by the house for the purpose of selling goods. This is a very serious charge, and for the sake of honest expert work it should be met in every case by emphatic denial on the one side, and the most careful investigation on the other. Every expert should repudiate the charge of disloyalty and defend his integrity, and he should be defended as well by those who employ him. But if a charge is preferred of this nature the profession should investigate it, and expel the guilty parties from their ranks. Because of the great importance of this subject at this time, I am led to make the following remarks:

The moment a man enters a profession he is accountable to it, and he cannot escape his responsibility. From henceforth he is bound to protect professional and scientific interests. It is not the question of how well he serves the commercial interests of the house employing him, but how well he serves the profession that praises or condemns him. A loyal service to professional and scientific interest is met by reward, and

disloyalty merits the punishment of a traitor. If the commercial interests of the house employing him are benefited by the publication of his work as a scientific man on the drugs or preparations handled by them, then is his employment of advantage in a monetary sense. If, on the contrary, the publication of facts injures sales, then is his work of no avail to them. But in either case he is in duty bound to publish facts only, and it is a question whether he is not responsible if he withhold facts that he may discover, even if their publication is not advantageous to demand, for when he places himself before the profession as a scientific man, he is bound thereby to tell all he knows when his professional opinion is asked for, otherwise his opinion cannot be regarded as an honest one. Opinions cannot be expressed nor articles written merely for the purpose of selling goods. To be scientific, they must contain the truth, the whole truth, and nothing but the truth, to the extent that truth may be obtained. A physician in the employ of a commercial house, therefore, is held accountable that his opinions and writings shall represent his honest conviction from a scientific point of view, and his views have weight with the profession only to the extent that they believe in his competency and integrity. He is, therefore, placed in the position of an expert, and held personally accountable for what he says. If, for example, an article is requested from his pen with regard to the therapeutics of a new drug or preparation of the same, it is equivalent to a demand upon him for his opinion as an expert, and must be so regarded, and, in the delicate relation which he occupies to professional and commercial interests, he should be specially guarded as to his utterances.

A false assay of ore on the part of a chemist in the employ of a mining company, published by them for the purpose of foisting their stock on the market, would be met by public condemnation. It is apparent, therefore, that in a case of this kind the reputation of the mining company is dependent upon the reputation for integrity of the expert in their employ. In a similar manner, every physician in the employ of a commercial manufacturing pharmaceutical house should be held responsible; then his competency and integrity will guarantee the honesty of the house employing him, and his name, in connection with the house, always be an honor to both parties concerned. But if it be proved that a physician in the employ of such a house is merely a tool in their hands for trade purposes, without regard to professional and scientific interests, and that his opinions are biased by his relations with the sale of the drug or its preparation, then is he a disgrace to the profession to which he pretends to belong; and if a house should seek to blind the profession by using such a pretender as a catspaw to rake their chestnuts from the fire, they, too, would merit the disdain of all honest men.

Very respectfully yours,

F. E. Stewart, M.D., Ph.G.

Philadelphia, March 12, 1883.

BROMIDE OF ETHYL AS AN ANÆSTHETIC.

To the Editor of The Medical News.

Sir: There seems to be a disposition in some quarters to return to the use of bromide of ethyl for anæsthetic purposes, and it is urged in its favor, that it is admirable for brief operations on account of the rapidity of its action. In view of these facts, I beg to call attention to some experimental trials of this article by self-inhalation, the results of which were published in the *Cincinnati Clinic and Lancet*, April 10, 1880, page 327. By three different trials I fully learned the rapidity of its action, and the very brief period required for all its effects to pass off. There was, however, one other very important effect. In each instance the pulse showed a very great and rapid increase of rate. The figures were—from 80, before inhalation, to 100; from 80 to 120; from 78 to 120—as observed by medical friends who were present. This great change took place *within the first minute or first minute and a half of inhalation!*

Now the object of this note is to call the attention of gentlemen who are using bromide of ethyl as an anæsthetic to this point, that it may be ascertained whether this effect is general or only exceptional. It is to be hoped that some observations will soon be published. If the effect is general, then it would seem impossible, from a theoretical point of view, that an anæsthetic causing such great and sudden changes in the heart's action can be safe. Yours, etc.,

J. C. Reeve.

Dayton, Ohio.

NEWS ITEMS.

NEW ORLEANS.

(*From our Special Correspondent.*)

The Death from Chloral Hydrate in the Charity Hospital, referred to in The Medical News, of Feb. 3, 1883, occurred in one of the late Prof. Hawthorne's wards, some ten years ago. The case was mentioned merely as a point of information, and not in criticism of any former, or the present, management of the hospital. It is scarcely within the reach of human perfection to conduct a hospital with eight hundred beds, in such a manner that some accident or mishap, involving a human life, shall not occasionally occur.

The State Medical Association of Louisiana will hold its next session at Shreveport, beginning on April 4th. The obstructions to a successful organization of a State Medical Society in this State will in a short time be quite nearly removed. Formerly the meetings have been held in New Orleans, and a physician living in Philadelphia could attend them with less inconvenience, or sacrifice of time, than those living in some of the parishes of Louisiana. The roads completed and under construction will in a great degree obviate this difficulty. It is trusted this will afford an opportunity, which will be improved, to unify the medical profession of this State.

It is expected that the coming meeting will be largely attended by the country members of the profession. If this expectation is realized, it will prove to be a meeting of interest, since the rural moiety of Louisiana practitioners comprises much talent and cultivation.

It is not yet known what reports or papers are to be presented.

Smallpox still prevails in this city, the fatal cases last week numbering 40; 10 whites, 30 blacks. So far in this year the total record of deaths: whites 65, colored 122.

The Carnival (February 6th) attracted a large concourse of people to this city. We rightfully accuse the Mohammedan and the Hindoostanee pilgrimages and festivals, of carrying cholera through large portions of the Eastern World; and also of planting the infection on lines of travel which introduce it into Europe and thence to America. Is it not time that intelligent and conscientious sanitarians shall demand that some precautionary measures be exercised in this country touching popular convocations in times of danger from portable diseases? It would not be an immodest demand, which insisted that every person who choose to

attend a popular assemblage in a town where smallpox was known to be prevailing, should be required to give proofs of protection before entering the town. It would be still more important to require him to give satisfactory evidence on leaving the infected town, that he was not to prove a carrier of fomites to some uninfected and unguarded population.

DETROIT.

(From our Special Correspondent.)

The Annual Medical Commencements at Detroit.—The oldest, *The Detroit Medical School*, held its closing exercises on the evening of February 28th. It gave diplomas to its entire Senior Class, thirteen in number. Dr. H. O. Walker delivered the valedictory address, and Prof. Chas. A. Kent discussed the question, "How Shall We Protect Society from Medical Imposition."

The Michigan College of Medicine held its closing exercises on the evening of March 5th. It gave the degree of M.D. to twenty-eight of its Senior Class. One, we understand, failed to get the prize. The public address was given by Rev. E. P. Rexford, and the valedictory by Dr. J. B. Book.

After its public exercises each college invited its graduates to a banquet at the same hall, where they were presented to a large number of the medical profession of Detroit and adjoining towns. Excellent music and a profusion of flowers rendered the stage and the general exercises very attractive to the large audience attending each commencement.

The terms just closed have been in both schools more than usually prosperous. Yet there have existed constant rumors of negotiations looking towards a consolidation of the two schools. It is to be supposed that the object of those seeking this union has been to make one still more vigorous institution, that should be more profitable to its stockholders.

The spring terms of the colleges will go on as usual, great effort having been made to render them worthy of the attention of students.

The Commencement of the Medical Department of Michigan University is not held till June.

Importation of Smallpox from Rio Janeiro.—On February 28th the emigrant inspector at the New York quarantine discovered a case of smallpox among the crew of the S. S. Ptolemy, just arrived from Rio, whence she had sailed on January 24th. At the time of her departure from that port the disease was causing from twenty to thirty deaths weekly. The surgeon of the vessel gave the assurance that the case had been isolated from the beginning, but another of the crew was found suffering from symptoms which were regarded as suspicious. This man was removed to the quarantine of observation, where on the second day the eruption was developed, and he was sent to the hospital at Blackwell's Island. Some time before the arrival of the vessel two seamen were taken sick, but not with smallpox. The surgeon, however, with mistaken zeal, put them into the same room with the case first developed. On the third of March the disease appeared in these men also. The clothing of the men who were in the ship's hospital was disinfected, and their mattresses burned. The remainder of the crew were vaccinated.

Sanitary Council of the Mississippi Valley.—The fifth annual meeting of the Sanitary Council of the Mississippi Valley will be held at Jackson, Miss., beginning on Tuesday, April 3d, proximo. In view of recent action—legislative and judicial—affecting the sanitary interests of territory not embraced in the Council, in common with the Valley proper, invitations are extended to prominent sanitarians and health officials in the South Atlantic and Gulf States. It is hoped that such invitations will be generally accepted.

Death from Chloroform.—A press dispatch from Norfolk, Va., states that a lady in that city on March 9th, died under extraordinary circumstances. She had been in the best of health, but suffered from an occasional attack of neuralgia, which was ascribed to an ulcerated tooth. Chloroform was administered after the usual custom, for the removal of the tooth, but after it had been successfully drawn the lady was found to be dead. The chloroform had been administered by her husband, who is a physician, and the usual precautions were taken.

Michigan Sanitary Convention.—A Sanitary Convention will be held at Reed City, Michigan, under the auspices of the State Board of Health, on April 26 and 27th. The objects of the convention are stated to be the presentation of facts, the comparison of views, and the discussion of methods relating to the prevention of sickness. Dr. E. S. Richardson, of Reed City, is Secretary of the Convention.

Among the subjects which it is expected will be presented and discussed are the following:

How Diseases are Contracted and Communicated.

The Contagiousness of Diphtheria.

Personal Liberties *vs.* Public Health Laws.

Coöperation of Citizens with Sanitarians a Necessity in Preventing the Spread of Disease.

Medical Humbuggeries.

The Ventilation of Ordinary Dwellings.

Food and its Adulterations.

The Disposal of Slop-water and Waste Matter in Villages.

Drainage and Sewerage.

The Water Supply of Reed City and the Dangers of its Contamination.

Corrupt Traffic in Dead Bodies.—In his message to the Legislature of Massachusetts, Governor Butler called attention to the management of the Tewkesbury Almshouse and severely censured the course alleged to have been pursued by Mr. Marsh. Mr. Marsh has been in the institution for twenty-five years. For the past five or six years infants have not been retained in the institution, but have been farmed out. While they were cared for in the institution, however, Governor Butler charged that from 150 to 250 infant corpses were annually sold as merchandise to a single medical institution in the State for from $3 to $5 each. It was also charged that the bodies of adult paupers were sold secretly and not in accordance with the law.

A representative of *The Journal* recently visited the almshouse to make an investigation and to see what defence Mr. Marsh would make against Governor Butler's charges. It appears that there are in the State four medical institutions authorized by law to receive subjects from the almshouse. During the past ten years the number of deaths was 2,766. Of this number only 585 of the pauper dead were delivered to those institutions. The superintendent has no record of what became of the other bodies. He says that they were buried in pauper graves. He admits that if he had sent all the subjects to the medical institutions he could not then have supplied the demand. In view of this, the question is naturally raised, Why did he bury them when science demanded them and the laws allowed them to be used for scientific purposes? The inference is that, as Governor Butler says, the super-

intendent has sold many of these bodies for his own benefit, inasmuch as no record of the sale or the burial is kept.

Proposed Sewerage of Charleston, S. C.—The Department of Health, of the city of Charleston, in its annual report for 1882, urges the importance of a system of sewerage. "When it is realized that we have over six thousand vaults in our midst, that there is annually expended for cleaning them a sum of money approximating in amount an annual interest on the $300,000 of capital necessary for complete sewerage; when we know that the ocean flows and ebbs in and around us twice every twenty-four hours, that we are not located on a small sluggish river, as some cities are, it is most extraordinary, with our mortuary statistics for constant admonition, that the citizens of a city so favorably located for complete cleanliness should remain longer inactive on such a subject." The mortuary statistics, referred to, are for the year: Total deaths, 1726; of whites 554, of colored 1172, equivalent to a rate of 33.01 per 1000 of the whole population, or of 22.32 for the whites and 42.91 for the colored.

The Manufacture of Segars in Tenement-houses.—Governor Cleveland, of New York, last Monday signed the bill prohibiting the manufacture of segars in tenement-houses in New York City.

The University of the City of New York held its forty-second annual commencement last Tuesday. The degree of M.D. was conferred on one hundred and sixty-four candidates. The Faculty prize of five hundred dollars, for the highest standing in the class, was awarded to Henry P. Loomis, a son of Prof. Alfred L. Loomis. The prize of three hundred dollars, for the best competitive examinations in the seven general departments was awarded to Le Roy W. Hubbard.

Miami Medical College Commencement.—The commencement exercises of Miami Medical College took place at Cincinnaiti on March 1st, forty-one graduates receiving the degree of Doctor of Medicine. The valedictory address was delivered by Dr. Joseph Eichberg, Professor of Physiology.

Commencement of the Buffalo Medical College.—The commencement exercises of the Buffalo Medical College were held on February 27, 1883, the degree of M.D. being conferred on fifty-one candidates. Dr. M. D. Mann delivered the valedictory address.

The Philadelphia Ophthalmic and Aural Book Club has just been organized in this city, with the object of circulating among its members the literature of these specialties.

Confiscation of Austrian Medical Journals.—In one week the *Wiener Medicinischen Blätter* was confiscated on account of its article on the Military Sanitary Service: the week before the *Medicinisch-Chirurgisches Central-Blatt* met with a like fate on account of an article on the civil appointment of physicians, and at the same time the *Pharmaceutische Post* was also suppressed for its criticism of a recent decree of the Austrian Minister of the Interior.

Duration of Medical Education.—The number of years that a student has to spend at a medical institution prior to being admitted to examination for a medical degree, in various countries, is as follows: Sweden, ten; Norway, eight; Denmark, six and seven; Belgium, Holland, Italy, and Switzerland, six; Russia, Portugal, Austria, and Hungary, five; France, England, and Canada, four; United States, three or two; Spain, two.—*Lancet*, February 17, 1883.

Dr. Leopold, of Leipzig, has been appointed Extraordinary Professor of Gynecology in the University at that place.

Statue of Bouillaud.—A subscription has been started in France for the erection of a statue in memory of Prof. Bouillaud. Angoulême, the place of his birth, has been selected as the locality.

Prof. Sanderson's Successor. — Mr. Albert Schafer, F.R.S., Fullerian Professor of Physiology at the Royal Institution, has been appointed Jodrell Professor of Physiology at University College, in the vacancy occasioned by the resignation of Dr. J. Burdon Sanderson, LL.D., F.R.S., appointed Wayneflete Professor of Physiology in the University of Oxford.—*Lancet*, February 17, 1883.

Consumption in Rhode Island.—From the registration report just issued we learn that the number of deaths caused by consumption, in 1881, was 706. This is much the largest number ever reported in Rhode Island in any single year.

Although the number is considerably larger than in any previous year, the proportion to the whole number of deaths, from given causes, is less than in many previous years.

The average annual proportion during a period of twenty years, previous to 1880, was 16.84 per cent. The proportion in 1881 was 15.12 per cent.

The proportions were 30.2 descendents of American parentage, and 60.8 descendents of foreign, in each 100.

The proportion of foreign parentage is much larger than ever previously reported.

During the year 1881 the largest number of deaths from consumption, in any quarterly period, occurred in the third quarter. This circumstance is not in accordance with the rule of many years.

Contrary to rule, also, was the occurrence of the largest monthly number of deaths in August. Following August in the order of largest mortality were January, May, March, April, and July.

In 1881, 377, or more than 53 per cent. of the whole number of deaths from consumption, were of persons between twenty and forty years of age.

From the statistics the inference is unavoidable that consumption, as a cause of death in Rhode Island, has gradually diminished since 1865. The facts shown by the statistics reasonably warrant the following conclusions:

1. That consumption, in the total population of Rhode Island, has gradually lessened in frequency of occurrence, or that medical treatment has been more successful in its cure.

2. That the lessened frequency, or more successful treatment of consumption, has been confined almost exclusively to the population of American parentage.

3. That the proportion of mortality from consumption has always been larger in the population of foreign parentage.

4. That the mortality from consumption, in the class of foreign parentage, has not diminished in proportion to the population of the same parentage, during the last twelve years.

In the city of Providence the statistics show the following important facts:

1. In the population of American parentage in Providence there has been a very remarkable change in the mortality from consumption during the last twenty-five years. In 1856 there was, in this popula-

tion, one death from consumption in 268.2; in 1880 there was only one death in 435.2. This decrease has been continuous during the whole period.

2. In the population of foreign parentage, in Providence, the *rate of mortality* from consumption has changed only very slightly in the last twenty-five years. In 1856 the rate was one death in 262.6 of the population; in 1880 it was one in 268.0; and during this time it has been both slightly higher and lower than these rates. The rate of mortality from consumption, among the population of foreign parentage, in 1880, was almost precisely the same as the rate in the population of American parentage in 1856.

Consumption as a cause of death has, as far back in years as comparative registration of death reaches, shown a larger mortality in proportion to the population, in Massachusetts, than it has in Rhode Island.

The statistics show that the proportional mortality, from consumption, has also diminished very considerably in Massachusetts, since 1865.

SANITARY PRECAUTIONS AT MECCA.—In a letter to the Sanitary Administration of the Ottoman Empire M. O. Noury gives the details of the epidemic. Three hundred and twenty-four deaths occurred in the holy city.

The sanitary measures prescribed for the pilgrimage, and enforced during the past season, have been ss follows:

1. At Mina, the labor required at the slaughter houses and at the ditches, where the remains of the sacrifices were thrown, was performed by Takrouris, under the supervision of fifty infantry soldiers. Eleven carts were constantly employed in the removal of the remains to the ditches, so that cleanliness was secured in the valley.

2. At Mecca the houses were whitewashed and the closets disinfected with lime.

3. Cleanliness was strictly enforced, both in public places and in private houses.

4. The prompt depopulation of the town and the starting of two caravans earlier than usual were steps recommended and carried out.

5. The sanitary service were warned of cases of sickness whether among pilgrims or in the permanent population of Mecca.

6. Provisions and liquors were kept under inspection.

7. Public latrines were cleaned, and a certain quantity of lime thrown into them daily.

8. The reservoirs of Arafat were emptied, cleaned, and refilled two days before the arrival of the pilgrims.

9. The reservoirs were placed under military guard to prevent pilgrims from bathing or washing their linen therein.

10. The sacrifice of animals otherwise than in the authorized slaughter houses was forbidden.

11. It was the intention to place a military guard around the slaughter houses, that the flocks of sheep might be kept there. Sheep found in the tents were to be seized and placed within the military lines.

12. The importation into Mecca of meat from the sacrificed animals, whether in a fresh or dried state, was prohibited.

13. Lastly, the skins of these animals, after being well salted and dried, had to be sent directly to Jedda by the owner or other interested party.

M. Noury refers to the fact that the first cases in the last two epidemics occurred among soldiers, but considers that these were not really the first cases, although they were the first cases verified. He considers that cholera has its birthplace in Hindoostan, and that it is always imported into the Hedjar by pilgrims. He recommends that quarantine against the East be rigorously enforced, and proposes that pilgrim ships should be subjected to an examination in the port of Jeddah additional to that at Camaran. This final survey would check previous errors, and expose false declarations and intriguing on the part of ship captains and other interested parties.

The sanitary measures in the thirteen articles were carried out, with the exception of the military guard, which the government promised to station around the slaughter houses. The want of it produced much uncleanliness in their neighborhood; but the regular employment of the carts and the Takrouris in the removal of the offal of the sacrificed animals did not give time for its putrefaction, so that this year the valley of Mina was kept in a more cleanly condition than at any former period. On this account the disease was not developed in its usual formidable manner either at Mina or at Mecca. Of course this satisfactory result was partly brought about by the prompt evacuation of the town immediately after the fêtes.

The local authorities collected from the slaughter houses nine thousand and twenty-nine skins of sheep, goats, and camels, besides several thousands of skins of sheep slaughtered in the camps. The total of the immolated animals must have been between eleven and twelve thousand, and this in a year when the pilgrims were comparatively few in number. Besides five hundred and five latrines provided at Mina, a special trench was dug for each tent. These thousands of trenches, and the excremental matter left anywhere by the lowest classes of pilgrims, exhaled a hurtful odor, for the neutralization of which the writer had tried in vain to obtain a disinfectant that could be used over an extent of country requiring three quarters of an hour to go from one end to the other, and half an hour for crossing its breadth.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending March 3, 1883, indicate that consumption has increased, and that remittent fever and typho-malarial fever have slightly increased in area of prevalence.

Compared with the average for the month of February in the preceding six years, erysipelas and neuralgia were more prevalent; and remittent fever, pneumonia, diphtheria, and whooping-cough, less prevalent during the month of February, 1883.

Including reports by regular observers and by others, diphtheria was reported present during the week ending March 3, and since, at twelve places, scarlet fever at sixteen places, measles at nine places, and smallpox (one case), at Detroit, March 3.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 5 TO MARCH 12, 1883.

BROWN, HARVEY E., *Major and Surgeon.*—To be temporarily ass gned to duty at Mount Vernon Barracks, Ala., during the absence on leave of Captain T. A. Cunningham, Assistant Surgeon.—*Par. 2, S. O. 17, Department of the South, March* 6, 1883.

HOPKINS, WILLIAM E., *First Lieutenant and Assistant Surgeon.*—The leave of absence granted December 28, 1882, is extended two months.—*Par. 5, S. O. 56, A. G. O., March* 9, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

MALARIAL REMITTENT FEVER.

A Clinical Lecture, delivered at the Charity Hospital, New Orleans.

BY S. M. BEMISS, M.D.,

PROFESSOR OF THEORY AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE IN THE UNIVERSITY OF LOUISIANA.

(Reported by J. H. BEMISS, M.D.)

GENTLEMEN: I ask your attention to-day to a case of continued malarial or remittent fever, whose clinical course and treatment you have recently had opportunity to observe. It is scarcely necessary to remind you how important a thorough acquaintance with this form of malarial fever is to its satisfactory treatment. Its specific cause is identical with that of the other malarial fevers. This is sufficiently proved by its occurrence at the same periods of the year, and in the same localities with other forms of malarial fever, and its convertibility with those other forms.

Its nosological classification is better expressed by the adjective "*remittent*" than by "*continued*," but if you carefully examine the charts of temperature which are being passed around, you will observe the striking parallelism between them and the temperature charts of typhoid fever so lately exhibited to you. You perceive, also, that while the charts show marked remissions, there is no decline of temperature to the normal standard until in the course of convalescence the remittent form of fever lapsed into the intermittent type.

Mr. W. H. Thompson will read the clinical notes, which have been carefully recorded by Mr. P. Michinard, Resident Student, and himself.

J. G., laborer, native of Germany, twenty-five years of age, was admitted to Ward 19, Bed 251, on the 17th of November, 1882. Arrived in the city on the day of his admission from some point on the Mississippi River above New Orleans. Gives a history of attack by a chill several days before admission, which was followed by fever which had not entirely left him, although he had a chilly sensation occurring every day. Temperature on admission 102.3°; pulse not counted, but rapid and somewhat dicrotic; tongue large, coated, and moist; spleen and liver not much enlarged, but there was tenderness on pressure over both; no tympanitis, or gurgling, and but little complaint upon pressure over abdomen; bowels constipated; urine non-albuminous.

Patient got five grains each of calomel and sodium bicarbonate; followed by two stools. After catharsis, he received ʒij liquor cinchonidiæ every third hour.

Nov. 21.—Temperature 103°; pulse 100; tongue, coated; complexion sallow, with flushed cheeks and injected eyes. Calomel and soda were repeated by the House Surgeon, followed by slight purgation, after which liquor cinchonidiæ was again exhibited as at first.

22d.—Temperature 101°; pulse 80. In the evening, temperature 102°.4; pulse 90.

23d.—Morning, temperature 101°.2; pulse 75. Evening, temperature 103°.4; pulse 84.

24th.—Morning, temperature 101°.4; pulse 80. Evening, temperature 103°; pulse 80. Liquor cinchonidiæ stopped; no stools since 21st; two Seidlitz powders produced one stool.

25th.—Morning, temperature 101°; pulse 80. Ordered surface sponged frequently with tepid water; diet of oatmeal and milk with iced barley water flavored with lemon peel for drink.

26th.—Morning, temperature 101.2°. Evening, temperature 103°; tongue coated; face flushed; complains of headache and abdominal pain. In the afternoon got a third dose of calomel and soda, each grs. vij.

27th.—Morning, temperature 101°. A very small stool followed the calomel. Liquor cinchonidiæ renewed and an amount representing thirty grains of the salt was given on the 27th, 28th, and 29th.

28th.—Morning, temperature 100°. Evening, temperature 103°.

29th.—Morning, temperature 101.5°. Evening, temperature 103°.

30th.—Temperature 102.5°. Cinchonidia solution stopped and ten drops of dilute sulphuric acid given thrice daily in ʒij compound tincture of cinchona. Patient thirsty, weak, and restless; no stool since 27th. Ordered beef essence, oyster soup, milk punch, thrice daily; for a drink, lemonade with bitartrate of potassium.

Dec. 1.—Morning, temperature 100.2°. Evening, temperature 103°. Patient restless and complaining of his costiveness; was allowed to take a Seidlitz powder, which produced two stools.

2d.—Morning, temperature 101°. Evening, temperature 102°.6; pulse 100°, weaker and somewhat dicrotic. Liquor cinchonidiæ in ʒij doses thrice daily substituted for tinct. cinchon. comp. and acid. Sustaining diet and stimulants.

3d.—Morning, temp. 101°. Evening, 102.8°.

From the 3d to the 6th, too little change in patient's condition to be worthy of note. He had no stool from the 2d to the 7th, when a stimulating enema produced the desired effect.

8th.—The first decided tendency to cure by conversion into the intermittent type exhibited itself. The temperature on this day was, morning, 99.6°; evening, 100.6°.

9th.—Morning, 98 6°; evening, 101°.

10th.—Morning, 98°; skin bathed in perspiration; evening, 100°.

On the 13th treatment was limited to dietetic and hygienic measures. On the 15th, slight rise of temperature was met by a recourse to quinine.

Chloral hydrate and bromide of potassium were occasionally administered, to induce sleep.

The first question you desire to hear discussed is, What is remittent fever, in point of pathology? In other words, what constitutes the difference in the morbid process of remittent fever as compared with the morbid process of the intermittent form, both being produced by the same toxic agent?

Now, in endeavoring to answer this question so as to instruct you properly, I think I may safely postulate the following proposition:

The typical form of malarial fever is the intermittent.

Let us understand one another on this point. Nature works by modes, whether in health or disease. We denominate these modes *laws*. The law of malarial fever is that the intermittent form shall be so predominant in numerical ratio, that the remittent cases should be looked upon as the exceptions, that is, the departures from type. I have in a previous lecture discussed the question of the relative frequency of quotidian and tertian cases.

If we admit this proposition, it is perfectly apposite to enter into an investigation of the causes which determine the departures from type.

I do not hesitate to ask you to adopt the succeeding propositions as being those which, in my opinion, most nearly explain the causes of remittent cases.

First.—Increased intensity of malarial intoxication, either from, *a*, the unusual quantity of poison received; *b*, more than usual toxic qualities of the poison; *c*, unusual susceptibility of individuals to the poison.

There can scarcely be a question in regard to the influence of the first and third of these minor propositions in determining graver attacks of malarial fever. I must say, however, that as it respects any knowledge we possess of altered qualities of the malarial poison, we are now, and in all probability will long continue to be, at fault. We can only assume that, like other organisms (and it appears to be such), one generation or crop is likely to differ in its constituent qualities from other generations or crops.

It is undoubtedly to one or the other of these causes we must attribute the fact that cases of remittent fever are relatively more numerous in certain malarial localities, especially those situated in the tropics, where frosts do not occur to interrupt its continued evolution.

Second.—Another cause of remittent attacks is the concurrence of inflammations. If any form of acute inflammation complicates a case of intermittent fever, the febrile movement at once assumes a continuous type, for that fever which accompanies inflammations persists as long as the exciting cause is active.

Third.—Intermittent attacks may become continued in type from accumulations of secondary poisons in the blood. It is not improbable that this may be reckoned as a very common cause of the conversion of intermittent into remittent.

Fourth.—The natural history of intermittent attacks shows a marked and almost constant tendency to an increase in violence with each recurrence of the paroxysms. This aggravation is likely, not only to increase the degrees of temperature records, but also to shorten the period of intermission until the fever becomes persistent.

It appears to me that this mode of study ought to be of much practical value in directing your attention to those variations in the ordinary morbid processes of the malarial poison, which can in many cases be anticipated and prevented; and in other cases met by such appropriate treatment that restoration of the intermittent type shall simplify those cases which may not be summarily curable. When I first entered upon the practice of medicine, I am sure that I occasionally had some dozen cases or more, of these remittent attacks under treatment at one time. I now believe that they were principally due to a failure to cure intermittent forms, because of neglect or improper medication during the earlier periods of attacks. I generally found that attempts at cure had been made by non-professional persons. The main feature, if not the sole feature, of their practice, consisted in repeated purgation. The purgative which stocked every family chest was "Cook's Pills," consisting of one grain each of calomel, rhubarb, and aloes. It was customary to give from four to six of them at one dose, to be repeated once or twice daily, until the fever declined to that point which was supposed to render the preparations of cinchona admissible. It was then not only the popular idea that cinchona should not be given during fever, but it was one held by nearly all practitioners of medicine. But I have somewhat unintentionally gone into this digression.

I need not occupy much of your time in portraying the symptoms of this form of fever. You notice this patient had scarcely any symptoms common to typhoid fever. His bowels were costive—scarcely at all tender, or tympanitic; no ileo-cæcal gurgling or soreness; no marked nervous ataxia or delirium, and certainly no rose spots. This is not always the case. Indeed, I may safely say that it is so much the rule for bowel irritations to complicate remittent fever, that the physician should be upon his guard in his repetition of cathartics. I have seen patients die by exhaustion from excessive diarrhœa. I have also seen deaths occur from entero-peritonitis, and again have seen more than one death from intestinal hemorrhage when typhoid fever could be positively excluded. Notwithstanding these facts, we must not, from any analogy of symptoms in certain cases of remittent fever with those of typhoid fever, allow ourselves to be led into those common errors of diagnosis which classify them as examples of the latter disease.

It is proper enough to say that your remittent cases have assumed a typhoid condition, but to say they have "run into typhoid fever," as is too frequently done, is very wrong. It is a wrong to medical science, and a wrong and reproach to sanitary science, which demands that confusion in regard to the presence of communicable diseases, shall be carefully avoided.

Let me now lay before you the methods of treatment which my long and large experience has taught me to consider the best which can be adopted.

When called for the first time to a case of continued malarial fever, the leading indication should be to secure cinchonism. This should be attempted in any stage of the disease or condition of the patient. You must not trust to small doses of quinine, but employ it in sufficient quantity to fully test its therapeutic value.

If the departure from type is due to either of the causes stated under the first proposition, cinchonism may at once prove curative. I have seen excessive temperature abated, the dry skin become bathed in healthful perspiration; the tongue grow moist; the delirium cease, and the patient enter at once upon convalescence after a single saturation with quinine. If inflammations are present, you should not expect quinine to arrest them. But they are not in any manner prejudiced by its use; on the contrary, the antipyretic effect of this drug must exert a greater or less salutary influence over local inflammations.

If the departure from type is due to secondary blood impurities, the expectations of directly curative effects of quinine are also lessened, but by a judicious combination with some eliminant, we may meet the double indication of depuration and cinchonism.

The case now before you is probably classified with those which owe their departure from type to secondary blood impurities. The costive bowels, sallow and almost jaundiced skin, the fevered tongue and loaded urine, all indicate that this conclusion is correct.

You will observe that, in this instance, calomel and soda were administered, and their cathartic effect was waited for before prescribing the antiperiodic. It is only in rare instances that I delay the exhibition of quinine to await the action of preparatory medicine. This patient presented symptoms exceptionally favoring such a course of medication. The indications for depurative remedies appeared to be paramount. No injury seemed likely to ensue from a delay of cinchonism, as no excessive fever or other threatening symptoms were present. Each separate case calls for the exercise of good judgment, and a variation of treatment to suit the exigencies present.

In the great majority of cases which I have observed, I have thought it necessary to combine antiperiodic and eliminant treatment. Quinine may be given combined with blue mass, in the proportion of five or ten grains of the latter to every scruple of the former; or competent doses of calomel may be alter-

nated with the doses of quinine. The only precaution you need observe is in not exciting so much intestinal peristalsis as to carry your quinine out of the system before it has been appropriated. I had at one time a medical practitioner living neighbor to me, who treated his malarial cases with a mixture of sulphate of magnesium, quinine, and tartrate of antimony. You can scarcely imagine the unpleasant complications this treatment occasioned.

If the bowels are already inclined to be irritable, do not hesitate to combine enough opium with your cathartic to prevent too much energy or quickness of operation.

In quite a considerable proportion of the cases I treat, sufficient elimination is produced by bitartrate of potash given in ʒij doses to an ordinary tumblerful of lemonade; the patient being instructed to drink small quantities as often as thirst prompts a call for fluids.

In a ratio of grave cases differing in different years of epidemic prevalence of malarial affections, prompt cure will follow the treatment I have indicated. In another ratio no good results will be seen.

You observe in this patient's case the temperature continued to rise for three days, although ninety grains of sulphate of cinchonidia had been administered, preceded by calomel and soda. Whenever this failure occurs I advise you not to continue the quinine, increasing the doses in amount and frequency, as is often done, but stop it altogether. Persistence in its use under such circumstances is likely to produce aggravated physiological effects, and as the hindrance which prevented its curative action at first, is probable still to exist, it is better to await conditions of the system more favorable to its repetition. My rule is to place the patient under symptomatic treatment. As the fever is generally the most formidable symptom, we must carefully mark its course. The temperature should be recorded every six hours. Any intelligent person can be instructed to take observations in your absence.

The patient should be frequently supplied with cool drinks, rendered palatable by the addition of lemon, or of some of those home-made beverages which are known under the name of "shrub," such as raspberry, currant, the juice of the pineapple, or watermelon. Neutral mixture with small doses of digitalis and acetate of morphia may be given every third or fourth hour. The surface should be sponged often either with cold or tepid water. The hair should be cut; the bedding changed often, and the room kept cool and well ventilated. The diet should be of farinaceous articles, fruits, and milk, unless some ataxic symptoms call for meat extracts and stimulants. Insomnia should be carefully watched for, and relieved by chloral hydrate or opium.

Under this expectant treatment it is rare, indeed, that the oscillations of temperature do not, in the course of a very few days, become more marked, the change being most observable in the descent of the lower angles of the curves. As soon as this occurs, tentative doses of quinine should be resorted to. It is better to give it in solution, and in quite positive quantities. If you catch the patient when his temperature is at a decidedly lower range, give five to twenty grains of the salt at one time. After this watch its effects with sedulous care. If the oscillations of temperature are overcome by the quinine, everything will be well. If, on the contrary, they are not governed by it, resume your expectant medication, and await another opportunity to invoke the aid of antiperiodics.

Gentlemen, I have travelled this difficult road so often that I may venture to speak with some authority. But at the same time, I cannot close this lecture without reminding you, that in treating continued malarial attacks, while your own good sense must be the most important factor of success, there is an old Latin phrase which may give you important aid in its exercise, "*in medio tutissimus ibis*"—the middle and careful course is the safest.

THE MICROCOCCUS OF GONORRHŒAL PUS.

SECOND PAPER.

By GEORGE M. STERNBERG, M.D.,
SURGEON, U. S. A.

In my paper published in the The Medical News of January 20th and 27th, I give in detail the experiments which have led me to the conclusion that the infective virulence of gonorrhœal pus is not due to the presence of the micrococcus which is found in a certain proportion of the pus-cells, and which, so far as my observations go, is constantly present in the pus of *specific urethritis*. If I am right in my deduction that this micrococcus is an accidental parasite which has nothing to do with the special virulence of gonorrhœal pus, it is altogether probable that the same micro-organism will be found in the pus of *non-specific* urethritis. As this is extremely rare, I am not likely to have the opportunity of verifying the truth of this prediction, but mention the matter here in the hope that some practitioner who may have an undoubted case of this nature will look for the "*gonococcus*" of Neisser (Medical News, January 27th, p. 99) by the method which I have described (*loc. cit.*, p. 96). Evidence of this kind will, however, always be subject to the suspicion of a mistake in diagnosis, and the only satisfactory way of verifying the truth of the prediction would be to produce a urethritis, experimentally, by the application of some irritating chemical agent to the mucous membrane of the urethra. But if persons were found ready to place their urethræ at the disposal of science for this purpose, it would be necessary to guard against the criticism made by the reviewer quoted (*loc. cit.*) with reference to the experiment of Bokar upon six medical students, viz., that "the experiment would have been far more convincing if the dauntless three had been kept in solitary confinement for a week before or after the inoculation."

The most ardent devotee of science would hardly submit to this condition unless the question to be determined were one of paramount importance.

It is difficult to decide how much weight to give to the experiment of Bokar in the absence of detailed information with reference to the method of cultivation employed, especially as he is not known in this country as an expert in culture-experiments of this kind. The writer will therefore make no attempt to estimate the scientific value of the result reported, but if opportunity offers will repeat his own experiments, and will be quite ready to admit that the micrococcus present in gonorrhœal pus *is* the cause of infective virulence if he is able even occasionally to produce gonorrhœa by the introduction of a pure culture of this micrococcus into the urethræ of healthy persons.

The object of the present paper is to call attention to a later claim which has been made in support of the hypothesis of Neisser, with reference to the etiological *rôle* of this micrococcus, based upon evidence of a different kind.

In the *Medical Record*, of December 16, 1882, I find the following (p. 687):

"Dr. Leistikow thinks he has confirmed, by a series of experiments, the discovery made by Neisser, of the presence of a special form of bacteria in gonorrhœal discharges. In the first stage of a gonorrhœa, when the discharge is thick and abundant, but few of the bacteria can be seen. They exist, however, in great numbers in the thin and scanty secretion of the later stages, sometimes even when the disease has existed over a year. In the treatment of gonorrhœa the author employs an injection of corrosive sublimate, which Koch has found most fatal to the various forms of bacteria. He uses a solution of 1 part to 20,000, 1 in 10,000 being found to be too irritating. In private practice a still weaker solution of 1 part to 30,000 is employed. The injections are made three times a day, and should be continued for three or four days after all discharge has ceased. The bacteria disappear, or are greatly diminished in number, after one day's use of the injections, but return again if the latter are discontinued too soon. Treatment by injections should not be begun until after the acute inflammation has subsided.—*Deutsche Medicinal-Zeitung*, Sept. 7, 1882."

This may appear, at the first glance, to be pretty strong evidence in support of the view that infective virulence is due to the presence of this micro-organism; but, as I shall show, the evidence given is in reality rather in favor of the deduction to which my own experiments have led me.

We are first informed that Dr. Leistikow thinks he has confirmed the discovery made by Neisser, of the presence of a "*special form* of bacteria in gonorrhœal discharges." But I have already shown (*loc. cit.*) that this micrococcus is identical morphologically with that found in urine undergoing alkaline decomposition; and since my paper was written, I have had under observation a micrococcus from quite a different source, which also cannot be distinguished by the highest powers from that found in gonorrhœal pus. A pure culture of the micrococcus referred to was obtained by inoculating a culture-fluid with pus from a deep-seated abscess—whitlow—at the moment of its escape from a deep incision. The micrococcus from this source, cultivated side by side with that from gonorrhœal pus, was under daily observation for weeks, and, as already stated, no morphological differences could be detected.

The claim, then, that the "*gonococcus*" of Neisser is "a special form of bacteria" cannot be sustained.

We are further informed that

"in the first stage of gonorrhœa, when the discharge is thick and abundant, but few of the bacteria can be seen. They exist, however, in the thin and scanty secretion of the later stages, sometimes even when the disease has existed over a year."

This corresponds with my own observations, but does not support the view that these micro-organisms are the cause of the "thick and abundant discharge" of acute gonorrhœa, in which they are "but few." The evidence offered in support of Neisser's hypothesis as to the etiological *rôle* of this micrococcus is, however, of another kind, and depends upon therapeutical experiments in which a solution of corrosive sublimate was used locally in the treatment of gonorrhœa. According to the observations of Leistikow, "the bacteria disappear, or are greatly diminished in number, after one day's use of the injections, but return again if the latter are discontinued too soon."

I have made numerous experiments relating to the germicide power of mercuric bichloride upon this micrococcus, and am able to say very positively that this reagent does destroy its vitality in the proportion used.[1] I am, therefore, quite prepared to believe that "the bacteria disappear, or are greatly diminished in number." But is the gonorrhœa cured?

If it is true that the urethral inflammation and gonorrhœal discharge are due to the presence of this micrococcus, the injections of corrosive sublimate should have a specific curative effect, as this reagent is fatal to the micrococcus in the proportion of one part to 20,000. But we are told that the injections should not be begun until after the acute inflammation has subsided, and no claim is made that the course of the disease is aborted by the use of these injections, which are "to be used three times a day and continued for three or four days after all discharge has ceased."

It will be admitted that evidence of this kind does not give very strong support to the hypothesis of Neisser, especially in view of the fact that gonorrhœa may also be cured by frequent injections of a weak solution of zinc sulphate (one grain to the ounce of water), whereas, this salt has no germicide power whatever, even in very much stronger solutions.

Thus I have recently demonstrated by experiment, that this very micrococcus of gonorrhœal pus retains its vitality and multiplies freely in a suitable culture-solution after exposure for two hours to the action of a twenty per cent. solution of the salt in question. The undoubted value of this remedy, therefore, as an injection in gonorrhœa must be due to some other cause than germicide power.

Before closing, I beg leave to call attention to the fact that some of the wood-cuts illustrating my previous paper (MEDICAL NEWS, January 27th) are not very satisfactory, for the reason that the engraver has given the micro-organisms represented very irregular forms and indefinite outlines. Fig. 6, especially, falls far short of fairly representing the group of micrococci multiplying in two directions, which are seen in the photo-micrograph from which this figure was copied.

Unfortunately, also, several mistakes have occurred in the references to these figures.[2]

NOTES ON THE MANAGEMENT OF RINGWORM OF THE SCALP (TINEA TONSURANS).

BY ARTHUR VAN HARLINGEN, M.D.,
CHIEF OF THE SKIN CLINIC, HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

(*Concluded from page 298.*)

RINGWORM of the body is very apt to go along with ringworm of the scalp, and in examining a patient for the first time the body should be carefully looked over as well as the head. Also the surface of the body should be searched with care from time to time while the patient is under treatment, because scales and stumps of diseased hairs are always apt to be parting from the scalp, falling within the collar and dropping upon the neck, where, if they light upon suitable soil, they may sprout and grow and spread.

There is a good deal of difference in individuals as to the aptitude for catching ringworm. One may be in the midst of floating spores in the air of a school-room or public institutions where the disease is rife, without coming to harm from it, while another seems to offer the conditions needed for the growth of the fungus, which is continually springing up on some new part of the skin at the same time that, under treatment, it is being stamped out in another. In my experience, children with light, thin hair are more apt to show this susceptibility, while dark-haired children seem as a rule less prone to contract ringworm of the scalp, and are more easily rid of it when it happens to attack them. Weakly and scrofulous children are also much more prone to contract ringworm of the scalp in a stubborn form, and this lends an indication for internal treatment which experience shows to be useful. I refer to the employment of cod-liver oil, which is often brought into use with advantage in the treatment of chronic and inveterate ringworm of the scalp. A course of oil seems often to aid the external treatment to a marked degree. Arsenic I do not think is so useful; at least it has not proved of much benefit in my hands, though others speak of its advantages.

Although I do not intend in this article to go over the rather hackneyed subject of remedies for ringworm of the scalp, yet as a part of the management, I shall now mention some of the applications which have proved most beneficial in my experience.

Prominent among these is carbolic acid, which I use not only to destroy the parasite in the diseased patches, but also to act as a preventive in checking the spread of the fungus to healthy parts. For this purpose I use a mixture of one part of carbolic acid with three to six parts of glycerine. This is rubbed into the whole scalp, or into the entire scalp saving the affected patches, every day, and not only tends to put an end to the life of the fungus, but also prevents its spread from the patient to other persons. A carefully cleansed scalp becomes covered with fine epidermic scales as soon as it is dry, and these branny scales containing fungus are brushed off and float about in the atmosphere, a constant menace to persons in the neighborhood, to whom they may carry the contagion. For this reason a child suffering from ringworm of the scalp should not only wear a linen cap constantly, but should have the scalp constantly saturated with carbolized glycerine.

A stronger carbolized glycerine (one part to two or three) may be applied to the patches directly by means of the swab I have described above, or with a bit of flannel on the end of the finger. Glycerine has a good deal of penetrative power and it gets down to the roots of the hair very nicely, carrying the carbolic acid with it. I sometimes succeed in curing quite severe cases of ringworm of the scalp by means of carbolic acid alone, using the stronger solution to the diseased patches, and the weaker preventive fluid elsewhere over the entire scalp.

Occasionally I make use of a blistering fluid, especially when the disease is recent and tolerably extensive but superficial, and where the fungus has only penetrated the follicles a short distance. I have the cantharidal collodion made somewhat stronger than that usually sold, and paint several coats over the diseased patches on the freshly shaven scalp. I do not think it safe to paint too large a surface at one time, and therefore usually do not exceed three or four square inches at any one sitting. It will be found that in pulling off the crust after the blister has collapsed and dried, quite a large number of diseased stumps will come away, the roof of the dried blister serving to depilate to a certain extent. The milder carbolic wash may usually be applied immediately after the blister has been removed.

Another application which I use in more inveterate cases of ringworm of the scalp is the oleate of mercury. This is used in six per cent. strength, and is mixed with acetic ether in the proportion of seven parts of the oleate to one part of ether. It has remarkable penetrative power, and gets down to the very roots of the hairs more quickly than any other application with which I am acquainted.

There are many other parasiticides in use. Some of these are very effective, and, in any case where one thoroughly used fails, another can be used. The following may be named as most likely to prove useful in the majority of cases. Thymol, boracic acid, picrotoxin, iodine alone, or in combination with tar or sulphur, mercurial preparations, and chrysarobin. As the text-books teem with formulæ for the employment of these remedies, I will not describe the method of their use.

The proper management of a case of ringworm involves of course the prevention of its spread, and this presents, in some cases, a problem difficult of solution. It is better that children who have ringworm of the scalp should be completely isolated from their fellows. This, it must be remembered, does not mean anything like solitary confinement. Owing to the fact that tinea tonsurans does not attack adults, a child suffering with this disease may mingle freely with older persons without any danger to the latter, beyond the possibility of contracting ringworm of the body, which, as is known, is very readily cured. Where complete isolation is impossible, the usual precautions are of course to be taken.

The promiscuous use of brushes, combs, towels, hats, etc., is to be guarded against. In addition, the patient should sleep in a separate bed, and, if possible, in a separate chamber. But the best means of isolation is to prevent the diffusion of the spores from the patient's scalp, and this may be attained by keeping it constantly saturated with the weaker preparations of carbolized glycerine above mentioned. The spores are thus kept from flying about in the air, as they will certainly do if the diseased scalp is allowed to become dry and scaly. The same application may be made to the scalps of other children who for any cause may be obliged to associate with the patient. In these the hair should be kept short, the scalp washed every day thoroughly, and an application of carbolized glycerine (one part to ten), made immediately afterwards. The patient should constantly wear a linen cap over the scalp, and the greatest care must be taken to disinfect, by dry heat, the various articles of clothing which cannot be boiled, or which it would be inconvenient to throw away.

The coat-collar is a very frequent nidus for the propagation of the ringworm fungus, because it is apt to rub against the scalp, and any stray scales dropping from the head are likely to light there. It should therefore be one of the points to be watched, and indeed if of cloth should be temporarily covered with some linen or cotton fabric which can be washed.

It should be remembered that ringworm in children not unfrequently originates from contact with domestic animals, particularly cats and dogs. In the management of such cases this cause of contagion should not be overlooked. Two little boys recently came under my care suffering from ringworm of the scalp, the cause of which remained a mystery until I ascertained that they were accustomed to pass hours of each day in a small hut which they had built in play, and where they lay for hours together each day in a bunk with a pet dog. The animal on examination proved to have "mange," in other words, ringworm.

It may be thought that in the foregoing remarks on the management of ringworm of the scalp I have gone too much into what appears to be trivial detail, but I am convinced that this is necessary, inasmuch as we constantly see failure to cure cases of ringworm where suitable and efficient remedies have indeed been prescribed, but where sufficient care has not been taken to have them properly applied.

The affection is a stubborn one, four to six months at least are required to effect a cure. In well-marked cases the friends and parents of patients should be told this beforehand to prevent misapprehension; a more favorable prognosis is almost sure to lead to disappointment. Where an apparent cure has been reached, the patient should still remain under the oversight of the physician for some months, and a very careful search should be made from time to time with a view to discover the presence of scurfy patches with broken-off hairs or the black dots marking diseased stumps.

A spontaneous cure sometimes occurs after the lapse of years, as the patient reaches adult life. The disease is rarely encountered in persons over twenty-one years of age.

CASE OF SUDDEN DEAFNESS FROM MUMPS.

BY GEORGE C. HARLAN, M.D.

THOUGH mumps has been frequently referred to as one of the causes of deafness, it is only recently that the clinical histories of a few such cases have been reported by Buck, Knapp, Moos, and Brunner. They may be found in the numbers of the *Archives of Otology* for 1882. In many text-books the subject is not even mentioned, and Brunner says that "Our experience on this subject is very small, and we have not been able to describe the exact clinical picture even, apart from the obscurity in which the pathologico-anatomical conditions seem to be involved." Knapp, also, observes that, "The clinical material for a comprehensive description of the affection, and for a discussion of its nosology, is still so scant as to encourage the publication of new observations." Thus encouraged, I have thought it worth while to report the following case, even if only to call attention more generally to the subject.

M. P., female, aged 23, states that three years ago she had mumps, and the day after the commencement of the attack there was a roaring sound in the right ear, and complete deafness on that side. There was no discharge, and no pain. For more than a month she was so dizzy that she could not walk in the street alone; there was an irresistible tendency to pitch forward, but she does not remember that the movement was more toward one side than the other. When in bed, she felt as if everything in the room were in motion, "like when you first come off a ship." There is still constant tinnitus, and the watch is not heard on contact; there is faint perception of the tuning-fork held on the mastoid, increased by closing the meatus; and it is also heard slightly for a few seconds when held close to the ear without contact. The external ear and membrana tympani are perfectly normal.

Toynbee wrote, long ago, that, "In these cases the nervous apparatus is evidently affected, as the deafness comes on suddenly, is usually complete, and, as a general rule, no appearance of disease can be detected in the meatus, membrana tympani, or tympanic cavity," and no one not determined to ignore the labyrinth entirely in aural pathology could, with the histories of the cases recently reported before him, locate the lesion in any other part of the ear. As there was no indication of cerebral complication in any of the cases reported, it may, perhaps, be conceded that the labyrinth is the seat of the disease. What is the nature of the disease, why it attacks the labyrinth, and how it gets there are, in the absence of post-mortem observations, still subjects of conjecture. The suddenness and completeness of the deafness point to rapid and copious serous effusion, and by most of those who have discussed the affection it is considered to be a metastatic one, similar to the well-known orchitis. Such an exudation might easily destroy

the function of the delicate tissues in the labyrinth, and the subsequent disappearance of the vertigo may be attributed to the absorption of the fluid.

An interesting point in the case just reported is that a very slight, but certain, degree of hearing remained. Brunner says that the deafness is complete, and, according to past experience, is incurable; but Toynbee admits that the nerve is not necessarily wholly paralyzed, and that a very slight degree of hearing may remain. Knapp suggests that all metastatic affections of the ear need not necessarily result in total deafness, and that the affection may not be so rare as has been supposed, as many mild cases may have escaped detection. It is even quite possible that a decided degree of deafness, in one ear only, might fail to attract attention during the course of a painful disease, and hearing be subsequently restored.

HOSPITAL NOTES.

BOSTON CITY HOSPITAL.

Service of Dr. W. H. Thorndike.

ABSCESS OF THE TIBIA TREPHINED.

(Reported by Royal Whitman, M.D., House Surgeon.)

The patient, a man, twenty-nine years of age, entered the hospital October 9, 1882, with the following history: In 1874, without apparent cause, he commenced to have acute pain in the upper part of the right tibia; this was accompanied by more or less swelling and redness in the surrounding tissues. These symptoms passed away in about two weeks, though a certain amount of enlargement in the bone has persisted. He remained perfectly well until 1879, when he had a secondary attack. Since then he thinks that the bone has slowly enlarged, though he has had no pain or other symptoms until about eight weeks before his entrance to the hospital, when he again had sharp pains in the head of the tibia. These pains, which were deep-seated and boring in character, were worse at night, shooting up and down the leg. Since then he has gradually lost appetite, flesh, and strength, and has occasional night-sweats.

Examination shows the tissues over the head of the tibia to be tender, red, and slightly œdematous. About two inches below the tubercle is a point of localized tenderness. The head of the tibia is about one inch larger in circumference than that of the corresponding bone.

On October 9th Dr. Thorndike made a crucial incision over the point of greatest tenderness. The periosteum was found to be thickened and inflamed. This was retracted from the surface of the bone. The trephine (three-fourths of an inch in diameter) was then applied, and at a depth of three-fourths of an inch from the surface pus was reached, and about one-half an ounce was evacuated. The cavity of the abscess was then thoroughly cleaned with carbolic solution. The operation was done under spray, and the wound was dressed with carbolized gauze. After the operation the pain was almost completely relieved. The patient rapidly gained flesh and strength, and was discharged from the hospital in three weeks, with but a small opening from which a small amount of pus was discharging. He is now almost entirely well.

MEDICAL PROGRESS.

Relation of Tubercle Bacillus to Phthisis.—Dr. C. Theodore Williams publishes the results of the examinations which have been carried on in the Brompton Hospital for some months with a view to test Koch's conclusions. The number of patients whose sputum has been tried is one hundred and thirty. The method used was that of Dr. Heneage Gibbes, the staining being accomplished by his magenta aniline solution and chrysoidin; in some later slides methylene blue was substituted for the chrysoidin. The specimens tested were either taken from the sputum collected during the twenty-four hours or from that expectorated in the early morning, and the rule adopted has been in the case of a negative result to repeat the examinations two, three, or four times, so as to insure accuracy. Twenty-one patients were examples of various lung affections other than phthisis. In no one of these did the sputum contain bacilli. The one hundred and nine phthisical cases consisted of acute and chronic forms, and included instances of tuberculo-pneumonic phthisis, of scrofulous pneumonia, of fibroid, catarrhal phthisis, and a large number of cases of chronic tubercular phthisis. Cavities were detected in one or both lungs in eighty-one of these patients, nine were in the stage of early consolidation, the rest were undergoing softening, or were cases of old tubercular induration with emphysema or fibrosis. In the one hundred and nine phthisical cases he detected bacilli in one hundred and six, and even of these three, in one it could not be affirmed with certainty that they were absent.

So far his results agree with those of previous observers as regards the specific character of the bacilli, and the fact that none were found in the cases of bronchiectasis, in which the expectoration was extremely fetid and abundant, separates the tubercle bacillus from any of the numerous organisms connected with fermentation and decomposition.

Most of the consumptive patients had cavities, but nine were cases of early consolidation. These were all cases in which both the history and the physical signs forbade any suspicion of a cavity, and he offers them as a proof that the bacilli are found in connection with tubercle formation, and not only with softening and excavation.

Temperature observations were carefully taken in all the one hundred and nine cases, and in fifty-one pyrexia, ranging from 100° to 105° F., was present at the time of the examinations. In some of these pyrexial cases the bacilli were very abundant, but in others, though the sputum was abundant, bacilli were few, this in spite of numerous careful observations.

With regard to the proportion present during periods of quiescence or arrest of the disease, he should regard their total disappearance as an eminently favorable sign. Out of four cases of contracting cavities where very favorable changes were progressing, bacilli were detected in three, but in small numbers; in the fourth case, above mentioned, none were found. Therefore, we are hardly justified in concluding that there is any definite ratio between activity of disease and number of bacilli, though as a rule they are few in cases where the disease is quiescent.

He has suspended glass plates covered with glycerine in the extracting flues of the Brompton Hospital, and thus subjected them to a stream of air with a velocity of three hundred or four hundred feet a minute issuing from numerous wards containing consumptive patients. In this way he sought to obtain a concentration of the exhalations, and on testing the plates they were found to contain abundant bacilli.

While, however, the bacillus must be duly considered

in the origin of phthisis, it may be regarded as a more or less exciting cause of the disease, requiring a previous weakening of the constitution to enable it to act.

In the discussion which followed the reading of this paper before the Medical Society of London, DR. HERON said that the bacillus had now been found in many organs, and in the living subject, in the sputum, in the urine, in an ulcer of the tongue, in lupus, and in an unopened knee-joint. He had found the bacillus himself in fifty-four cases of phthisis, and he believed that practically it would always be found in cases where physical signs of phthisis existed. But in some of these cases the physical signs were so slight that he should have hesitated to make a diagnosis without the aid of the bacillus. As regards prognosis, he believed a few bacilli betokened a chronic course; a large number and persistence of them indicated a rapidly fatal course. The same results had been obtained by Balmer and Fraentzel. In rapidly sinking cases the bacilli were found in large numbers, often grouped into masses. This grouping indicated an unusually rapid course, and in one or two cases it had preceded by a day or two an aggravation of the symptoms. Some observations appeared to show that the bacilli might appear before physical signs were manifest. In some cases the bacilli, which had been present in moderate amount, had disappeared from the sputum for several weeks. In such cases he thought that the patient might be considered to be in a fair way of recovery. Heredity he had found to exist in thirty per cent. of his cases at Victoria Park Hospital during four years.

DR. HENEAGE GIBBES directed attention to two points: first, the difference in the structure of miliary tubercles in the lungs and the relation of the bacilli to those of different forms; and, second, the presence of bacilli in the smallest or commencing tubercles. He had examined a large number of lungs affected with the reticular form, and had only succeeded in finding bacilli in three cases, and these in small numbers, distributed through the reticulum. In the non-reticular form, however, he had invariably found bacilli in large numbers in the caseous centre. Dr. Gibbes also pointed out that the bacilli were to be found in the smallest tubercles. A lung may be stuffed with tubercles, each one containing thousands of bacilli, and yet the patient will die before the destructive process has gone far enough to cause any of them to be ejected with the sputum. Thus there were two forms of fatal tuberculosis in which no bacilli could be found in the sputum.[1]—*Lancet*, February 24, 1883.

THE ACTION OF QUININE AND CINCHONINE.—M. BOCHEFONTAINE has found from experiments made in VULPIAN'S laboratory that the action of these two substances is very much the same, though quinine is less of a convulsivant than cinchonine. On the other hand, quinine is the most poisonous. As regards the elimination of these alkaloids, he has found that when injected hypodermically they may be found in the vomited matters, showing that they may be eliminated by the stomach. It is well known that quinine is much the most efficacious therapeutically.—*Revue Scientifique*, February 24, 1883.

THE VOMITING OF PREGNANCY.—MR. BROCK discards the numerous theories which have been proposed to account for obstinate vomiting in pregnancy, and believes that it arises simply and purely from an idiosyncrasy in the individual. Vomiting, of course, may be aggravated by other conditions present, such as undigested matters in the alimentary canal, etc.

He thus summarizes his principal reason for coming to this conclusion.

1. That obstinate vomiting occurs in multiparæ, where the uterine tissues are lax, and where the os is soft, easily dilatable, and even patent enough to admit the tips of two fingers. This causes him to reject the theory held by Bretonneau and Barnes.

2. That obstinate vomiting is absent in the majority of cases where there is a rigid state of the os, and where one would almost expect it invariably to be present, if the cause were that assigned by Dr. Barnes.

3. That obstinate vomiting is often absent in flexions and distortions of the uterus, and often present where there are no flexions or distortions. This would not be likely if Dr. Hewitt's theory were true.

4. Obstinate vomiting is often absent in inflammatory conditions of the uterus, and present when there are no inflammatory conditions. This ought not to be the case if Dr. Bennett's theory be correct.

5. Because he believes a parallel condition is to be seen in other affections clearly influenced by the individual's neurotic constitution; for instance, obstinate sea-sickness, the occasional vomiting that takes place in pseudocyesis, the proneness to convulsions in certain children whenever ill; or, to take a specific case, the vomiting simulating the obstinate vomiting of pregnancy, in a non-pregnant woman, in whom the uterus was normal.

6. Because there is no definite line to be drawn between the ordinary cases of sickness in pregnancy and the more severe cases.—*Glasgow Med. Journ.*, March, 1883.

THE PATHOGENY OF CYSTS OF THE IRIS.—PROF. MASSE, of Bordeaux, reported in 1881 some experiments in which he had caused true cysts to develop in the iris in rabbits by grafting on the iris fragments of conjunctiva and skin. In some recent experiments he has also seen cysts develop in the iris in consequence of grafts of thin fragments of corneal substance. His method was to remove a thin layer of cornea by means of a Beer's knife from the lower border of the cornea, then to puncture the cornea at its upper border and to introduce the fragment, which was about four millimetres long by three broad, into the anterior chamber of the eye. The corneal fragment at once adheres to the iris, soon loses its transparency, and becomes vascular from the formation in it of vessels derived from the iris. Occasionally numerous cysts develop on the iris in the neighborhood of this graft, and may, he thinks, be also attributed to corneal tissue abnormally implanted on the iris.

He thinks that these experiments will prove that ordinarily the production of cysts of the iris is due to the penetration of the cornea by some cutting instrument, and the accidental carrying of some corneal, skin, or conjunctival fragment to the iris, to which it adheres, and then leads to the formation of cysts.—*L' Union Médicale*, February 24, 1883.

MYOMOTOMY.—A recent number of the *Zeitschrift f. Geburtshülfe und Gynäkologie* contains an article by PROF. SCHROEDER, of Berlin, on the extirpation of uterine fibroids, or myomotomy, as he prefers to term it. Although hitherto in this operation better results have, as a rule, followed the extra-peritoneal than the intra-peritoneal treatment of the pedicle, Dr. Schroeder thinks that, as in ovariotomy, the extra-peritoneal method will have to give way to the intra-peritoneal, and that the operation will not have been perfected until a satisfactory method has been devised of securing the pedicle in such a manner that it may with safety be left in the abdomen. The plan which Prof. Schroeder has followed is briefly this: First he ligatures, and then divides, the broad ligaments; then he cuts through the uterus, first peritoneum, then muscular tissue, in such a manner as to leave a strip of

peritoneum like a frill around the muscular surface of the stump. Then the surfaces of the stump are brought together; first the mucous membrane is united by sutures which are cut short, then the surfaces of muscular tissue are firmly secured in contact by sutures not involving the peritoneum; and finally the projecting ring of peritoneum, which has been left for the purpose, is brought together over the stump. An elastic ligature is put round the cervix before cutting away the uterus, and removed when the suturing of the stump is complete. If the tumor is so situate that it can be removed without opening the uterine cavity, of course the proceeding in simpler. Prof. Schroeder has operated sixteen times for uterine myoma, with thirteen recoveries. Of the three deaths, one took place from hemorrhage from the pelvic cellular tissue, one from sepsis, and the other was a case of Martin's operation.—*Med. Times and Gazette*, March 3, 1883.

The Blood-pressure in Man.—At the meeting of the Vienna Society of Physicians, held February 16, 1883, Prof. Albert demonstrated some blood-pressure curves which he had made on a man in whom amputation of the leg was performed. Before performing the operation the tibial artery was exposed, and a canula inserted and connected with a manometer, and the tracings were made on the kygmographion. The duration of the operation was only prolonged one minute by this experiment, and the course of the wound was not interfered with in the slightest. Some new and interesting results were obtained by this observation. Thus he proved that the blood-pressure was immediately greatly elevated by the assumption of the erect position of the individual (when narcotized), thus disproving the deduction of Marey made from experiments on the lower animals. No respiratory curves could be detected in the tracing. The absolute pressure corresponded very closely with the theoretical assumptions.—*All. Wiener Med. Zeit.*, February 20, 1883.

Bromide of Ethyl during Labor.—M. Lebert (*Lyon Méd.*, 1883) who has been employing bromide of ethyl largely in midwifery cases, accords it great value in simple confinements. It diminishes and finally suppresses the pain, without having any hurtful effect upon the mother or upon the child. He states also that under its influence labor is more rapid and surgical interference rendered less necessary. The subsequent recovery he believes to be speedier, and the tendency to flooding much less than when the drug is dispensed with.—*Glasgow Med. Journ.*, March, 1883.

Rickets and Syphilis.—Although some physicians have attributed to inherited syphilis an important part in the production of rickets, it is certain that this opinion is erroneous. Nevertheless, there is nothing incompatible in the two diseases; they may, unquestionably, coexist, and it is probable that the malnutrition due to the specific disease may be a potent factor in the development of rickets in such a case. M. Lannelongue has recently had the opportunity of examining the organs of a boy, aged three years, who presented the symptoms of both diseases. There was an undoubted history of syphilis on the maternal side. The child presented a characteristic rash about the bottom some days after birth, which lasted a long time, and was not treated. Some time later it suffered for six months from snuffles. The signs of rickets in the osseous system first appeared in the right humerus, then in the femur, and afterwards became general. At the autopsy areas of gray consolidation, having the aspect of gummata, were seen in the lungs. The bronchial glands were of a yellowish cheesy appearance, quite different, the report says, from that of tubercular infiltration. The liver was small, and its fibrous portions were thickened; the spleen was in a similar state. The osseous lesions were those of rickets. The epiphyses were soft and contained much "tissu spongoïde." Large oval swellings were present on the shaft, which, on section, showed a piece of atrophied ancient bone surrounded by much of the sponge-like tissue. The bones in places were seen to have suffered incomplete, but never transverse fracture. M. Lannelongue wisely refrains from drawing any positive inferences on the subject of the relation between syphilis and rickets.—*Lancet*, March 3, 1883.

Dilatation of the Neck of the Uterus.—M. Chassagny, of Lyons, in a communication made to the Paris Academy of Medicine, describes his method of thoroughly plugging the vagina, and producing rapid dilatation of the neck of the uterus. He places in the vagina a bladder, with which an India-rubber tube is connected; this, with the help of a siphon, conveys into it the water contained in a receptacle placed about two feet and a half higher than the pelvis of the patient. The bladder becomes distended by the water, and soon fills the vaginal cavity. This brings on abundant secretion, and induces energetic contractions, resulting in the physiological dilatation of the os uteri, which is quickly completed by the mechanical action of the bladder. The bladder is placed in the vagina, and the occlusion of the vulva is obtained by means of an apparatus which M. Chassagny calls the *Elytroptérygoïde* (wings in the vagina). It consists of a cylindrical speculum, which holds the badder; this is forced out as the water enters, and the act of distention separates the valves of the speculum, which, resting on the sides of the pelvis, prevent the expulsion of the apparatus and of the bladder. M. Chassagny mentions, in his pamphlet, several instances of induced premature labor, in cases of contracted pelvis, obstinate vomiting, eclampsia, etc. M. Chassagny describes two cases of vicious insertion. In both cases, he induced labor before the natural period by having recourse to rapid dilatation. There was not the slightest hemorrhage, and two living infants were born. In another case, where the mother was in the last stage of suffocative catarrh, M. Chassagny effected, in half an hour, the safe delivery of a living child. The mother rallied for a few moments only. In post-partum hemorrhage, the bladder, by completely filling the uterine cavity, closes the openings of the vessels, and, by artificially restoring the pregnant state, determines uterine contraction. The water in the bladder slowly flows away, until the uterus is thoroughly contracted.—*British Medical Journal*, March 3, 1883.

Laparo-colotomy for Removal of a Foreign Body.—At the last German Surgical Congress Uhde (*Beilage z. Cbl. f. Chir.*, No. 29, 1882) showed a wooden tool he had removed from the left colon of a man, aged 25, by laparo-colotomy. The tool was one used for sewing sacks, and measured nine and one-quarter inches in length, with a circumference at its thicker end of three and one-half inches. The patient, an inmate of a house of correction, had pushed this into his rectum on the 1st of June, 1882, and left it there. On the 25th of June a sudden movement of the body was followed by abdominal pain, and he found that the tool after that was not so easily felt from the outside of the abdomen as it had previously been. In July he suffered from feverishness, diarrhœa with bloody evacuations, tenesmus, and difficulty of micturition. In October there were rigors, with severe pain in the left hip and thigh. The pain increased so much that on 6th of April, 1882, he came to the hospital at Braunschweig for relief. At that time the foreign

body could be felt through the abdominal parietes to the inner side of the left antr. supr. spine of the ilium. On the next day an unsuccessful attempt was made to reach it by introducing the hand and part of the forearm into the rectum. On the 13th of April an incision was made in the left linea semilunaris, through which the foreign body was felt within the descending colon, jammed between the last rib and the sacrum so firmly that the colon was only brought to the wound by considerable traction. The piece of wood was removed through an incision in the gut nearly one and one-half inches in length, and this incision was closed with silk sutures. The operation was performed antiseptically, and, in spite of considerable vomiting and hiccough during and after the operation, the patient made a good recovery.

Similar operations, both successful, were performed by Reali in 1848, and by Studsgaard in 1878. In the former case the foreign body had been in the bowel for nine days, in the latter for twenty-four hours. In the present case it had been there for three hundred and seventeen days.—*Glasgow Med. Journ.*, March, 1883.

EXTIRPATION OF THE LARYNX.—J. F. COENEN (*Inaug. Diss.*) publishes an analysis of thirty-six cases of extirpation of the larynx, extracted from the well-known works of Schüller and Foulis, to which four new cases of Tilanus, Völker, and Hahn (two) are added. To this may still be added, one by Caselli (*Centralb. f. Chirurg.*, 1871, p. 159), one by Jochelson, one by Zeissl (*Centralb. f. Chirurg.*, 1882, pp. 420, 423), and two not yet published, making a list of forty-one cases. A report is given of the case of Tilanus, of Amsterdam, in which the operation was performed on a man, aged 51, on account of carcinoma. Death occurred in thirty-six hours after the operation, from collapse.—*Centralb. f. Chirurg.*, August 26, 1882.

IODOFORM IN SYPHILIS AND PHTHISIS.—PROFESSOR SCHNITZLER recently read before the Vienna Society of Physicians the notes of a case of syphilitic ulceration of the soft palate, tongue, pharynx, and larynx, complicated by tuberculosis, in which local treatment with insufflations of iodoform produced the most satisfactory results; the perforation of the soft palate became entirely healed, the swelling around the arytenoid corpuscles was reduced, and the tubercular infiltration of the lungs certainly was diminished. He also reported a second case of tuberculosis of the lungs and larynx, in which insufflations of iodoform, continued for five months, appeared to have no influence on the progress of the pulmonary disease, but the pain and irritability of the larynx, as seen in the hoarseness and cough, were decidedly improved.—*Wiener Med. Presse*, February 25, 1883.

PNEUMATURIA.—In two recent numbers of *La France Médical*, DR. GUIARD proposes the term "diabetic pneumaturia," to denominate a condition which he has observed in four cases of urinary affection in the male, complicated with glycosuria. This condition consists in an emission of gas from the bladder, and is said to be independent of any communication with the alimentary canal. The presence of the gas, which has been conjectured, but not yet proved, to consist chiefly of carbonic acid, is explained by the supposition that the glucose has undergone a process of fermentation in the urinary bladder. The escape of the gas occurs in an irregular manner during some part of the act of micturition, and may give rise to a gurgling noise. The existence of the fluid is manifest by no symptoms or physical signs apart from those significant of the associated disease. It has been thought by older observers that the mucous membrane was capable of exhaling gases, but that must be regarded as very problematical. Again, the introduction of air from without during the process of catheterism, especially where the bladder is hypertrophied and dilated, has been assigned as a possible explanation. Dr. Guiard has not been able to satisfy himself of the existence of the torula, nor of the usual products of the alcoholic form of fermentation. There seems to be no obvious reason why the torula should not be introduced from without, by means of the catheter, but until such an occurrence is proved, and until it is made more clear what the nature of the gas is, there can be but little use in speculating on the subject, which, under any circumstances, will hardly be regarded in any other light than in the nature of a clinical curiosity.—*Lancet.* March 3, 1883.

PRACTICAL APPLICATION OF KOCH'S DISCOVERY.—DR. GAIRDNER, of Glasgow, is of opinion that the practical applications of Koch's discovery are to be looked for chiefly in two directions. First, in that of prevention. "This discovery," he remarked at the Glasgow Medical Society, "imposed on medical men the necessity of looking to the observance of the most scrupulous cleanliness. They must have clean hospitals, clean wards and walls, clean rooms and floors. More than ever must this now be the order of the day. They must keep in view that no man was safe unless he got everything around him as clean and as pure as could possibly be managed. Another possible direction in which what they had learned might be applied (though the question was so obscure that probably even Koch would not push it), was in making experiments to ascertain whether the tubercle-bacillus could be cultivated into a milder form. Were this possible, the question might arise whether, as in the case of small-pox and anthrax, the milder form might be utilized as a prophylactic against the more virulent form. In the matter of cure, too, attempts must be made to apply the discovery. For the next year or two, there would be a run on the indiscriminate use of antiseptics in the treatment of phthisis; and probably this would result in disappointment. But this ought not to discourage them, as they might feel sure that, whatever residuum of utility there existed in the antiseptic treatment of phthisis, would eventually be made clear."—*British Medical Journal*, March 3, 1883.

THE VASO-MOTOR FUNCTIONS OF THE SYMPATHETIC.—MM. DASTRE and MORAT have made some new researches on the tonic and inhibitory functions of the sympathetic ganglia, and their relations to the vaso-motor nerves, of which the following are their conclusions: The ganglionic masses situated in the arterial walls have for their function the permission of an antagonism between the dilator and constrictor nerves; and while the inhibitory energy is mainly generated in these cells, the ganglia of the sympathetic system share with them the property of developing vaso-inhibition.

Thus, the superior cervical ganglion exerts a constrictor action on the vessels of the bucco-facial region. The inferior cervical ganglion and first thoracic ganglion exert a constrictor influence on the vessels of the auricular region: this action is reinforced by the constrictor nerves coming from the spinal cord through the third, fourth, and fifth dorsal nerves and their communicating branches. In opposition to this function, however, these same ganglia receive dilator nerves through the eighth cervical and first and second dorsal nerves, and this dilator influence predominates over the constrictor power; for stimulation of the communicating branches dilates the auricular vessels through the local peripheral ganglia.—*Revue Scientifique*, February 24, 1883, and *Gaz. Hebdomadaire*, February 23, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MARCH 24, 1883.

THE GERMAN CHOLERA COMMISSION.

THE Cholera Commission for the German Empire, which held its first session in Berlin in the summer of 1873, has just recently finished its labors. Prof. Pettenkofer, who was a member of the Commission, has made use of the occasion to review some of the more important results of the investigations, especially those which have a bearing on the so-called fungus theory (Pilz-Theorie). Credit is due Prof. De Chaumont for a translation of this important paper. The facts set forth by the Commission seem to leave no room for doubt that the causation of cholera depends on the operation of some of the lowest forms of life, though the discovery of the disease-poison has not yet been accomplished. In the opinion of Pettenkofer, cholera is an infectious disease of the miasmatic class, and its cause depends on conditions altogether external to the body affected (ectogenous).

While the *local* or *topical* view has been generally accepted by the Commission, there is a difference of opinion as to the manner in which the cholera-poison is propagated outside the body. Hirsch supports the hypothesis, "that from the cholera patient an infectious substance is actually thrown off, which, however, is not yet capable of acting directly as a cholera-poison, but only obtains its specific infecting influence after it has undergone a certain change, outside the system of the patient himself, and under the afore-mentioned external circumstances, either upon or in the soil (or a *succedaneum* of the soil)." But Pettenkofer prefers the other hypothesis, namely, "that the reproduction of the cholera-poison takes place quite independent of the cholera-stricken individual (as such), seeing that it may attach itself to persons, sick or well, or to other objects, through the instrumentality of which it may be carried from place to place, and wherever it finds appropriate conditions for its reproduction it may light up an epidemic."

That the disease has a certain relation to human intercourse is admitted, but that it shows a preference for places along the lines of railways does not appear to be borne out by the facts. Contact with the sick or mere intercourse with cholera-stricken places does not lead in itself to the spread of the disease; it is the locality to which the disease-germ has been brought, and in which favorable conditions exist for its propagation, that is chiefly concerned in the extension of the disease. Cholera cannot therefore be said to be a contagious disease in the strict sense of the term.

The water theory, which has so many zealous supporters in England, has been cast aside as untenable, at least the labors of the Commission have developed no facts which help to defend it. Unwholesome drinking water may favor the spread of the disease, but to it no greater influence is attributed than to bad food, or bad clothing. An abundance of pure drinking water is therefore insisted on only upon general hygienic grounds.

Pettenkofer is a firm supporter of the parasitic theory, and he considers himself sustained by the results of the work of the Cholera Commission in the belief that the poison of cholera is an organism which is spread by intercourse with places in which the disease is endemic or epidemic. The poison, when brought into other localities without being deprived of its active qualities, can be reproduced only when it finds in such places a suitable substratum or nidus, which is to be looked for in the soil, and serves as its nutriment or host.

The conclusions of the Commission in reference to the prophylactic measures suggested by the investigations, are of the highest practical value. The recommendations are as follows: "Of all the measures which may be applied to the prevention and combating of cholera, those take the first place which have for their aim the improvement of general sanitary conditions; all specific measures against cholera will prove unavailing, unless we pay the strictest attention in inhabited places to the purifying of the soil from organic and easily putrefying refuse, to the drainage of the soil, to the constant flushing of the sewers, to the frequent emptying of cesspits, to the careful inspection of dwellings, and closing those that are really hurtful, the provision of pure water both for drinking and other domestic purposes, and the like." The Commission expresses here the united opinion of the most experienced physicians, when it says, that the strictest attention

to all the measures demanded by public general hygiene offers the best protection not only against cholera, but against all other epidemic diseases; but that those measures will be successful only on condition that they are followed out continuously and at all times; for it is a fatal error to imagine that having recourse to them only at the approach of an epidemic will ward off the incursions of disease.

PREHISTORIC TREPHINING.

WHEN La Motte, in 1705, first treated epilepsy by trephining, he little thought that he was but reviving a prehistoric operation. Epileptics, and the "daft," as all who in their "teens" have read Cooper by the furtive midnight-oil well know, were objects of awe, and, perhaps in an earlier age, of veneration; and naturally fragments of the skulls of such persons very likely would be prized as amulets, protective against these and similar diseases. Moreover, the ignorant and degraded peoples of the Stone Age would scarcely discriminate between epileptic and ordinary convulsions, especially in children, and would be apt to attempt to remedy both by like means.

As early as 1868 M. Prunières discovered in the dolmens of La Lozère round pieces of human skulls, which he named "rondelles," or "cranial amulets," and made them the subject of subsequent communications both to the French Association for the Advancement of Science and to the Paris Anthropological Society. Various skulls also were found, which had evidently furnished such fragments. The shrewd eye of Broca, however, quickly observed that the smoothly rounded and bevelled edges were not the result of artificial polish, but of natural cicatrization, and that the skulls had been trephined in many cases long before death. He pointed out that they were not congenital, for they were not the normal symmetrical parietal foramina, nor were they the result of war or accident, since none existed in the forehead, nor were their shape or size consistent with the rude weapons of that period. Moreover, no evidence of fracture or depression was to be seen, such as would be inevitable were they of such origin. And though the skull discovered two years since by M. Parrot shows evidence of disease for which fronto-parietal trephining was done, yet this is a unique exception.

All the specimens thus far known are from the Neolithic, or Polished-stone Age, the cremation of the later Bronze Age having probably destroyed nearly all evidence of the custom, if it then existed.

Broca established the significant fact that the operation was performed in childhood, since all the evidences of recent inflammation had long since disappeared, and in one skull at least the deflection of the sagittal suture strongly toward the trephined side, was evidence of long-continued later growth.

The openings are always elliptical, one or two inches long, and a half inch or less wide, and bevelled at the expense of the outer table. They exist in both sexes, at all points covered by the hairy scalp, even in the line of the sagittal suture and the superior longitudinal sinus. In some, multiple openings exist, and some twenty skulls show the removal of the outer table alone by scraping, as was recommended by Johan Taxil in 1603 in his treatise on epilepsy. The edges of the rondelles cut from such skulls as Broca pointed out, are partly of the cicatrized margin of the opening made by the trephine and partly the rougher non-cicatricial margins, the result of posthumous trephining in the removal of the amulet from such highly prized skulls.

DR. ROBERT FLETCHER, of the Surgeon-General's Office, in his recent paper on "Prehistoric Trephining," in the *United States Geographical and Geological Survey* (from which chiefly we obtain the above facts), has summarized Broca's views, and has added all the more recent discoveries together with a number of excellent plates illustrating both the rondelles and the skulls from which they are obtained. Nearly all of the earlier specimens were found in France, but Wankel has found some in Bohemia, Dudik and Virchow others in Bohemia and Poland, and other observers have found a few in Denmark and Algeria. None have been found in Italy, Great Britain, or on this Continent. The remarkable Inca skull of Squier, with its ⩙ shaped opening, and those found by Gilman in Michigan, though they have perforations in the skull, are entirely different in character from the trephined skulls of La Lozère. The belief that epileptics were possessed by an evil spirit seeking escape would seem to have led to the operation, and Dr. Fletcher points out that the practice is not uncommon even at the present day among savage tribes, such as the Kabyles, of Algeria, and the inhabitants of the Loyalty Islands. Among the former multiple trephining is not uncommon, and M. Martin records the fact that some persons had submitted to it five or six times. Modern surgical experience shows that the operation *per se* is not a dangerous one (the serious injury which necessitates its performance being by far the most dangerous factor), and the fact that the Kabyles even resort to it in cases of pretended injury, in order to obtain "blood money" for violence done, is a marked confirmation of these views.

The trephine dates back to at least five hundred years before Christ. No such instrument, however, existed in the Stone Age, and the openings are of such character as to forbid the surmise that any

similar instrument was used. Most probably it was done by scraping, a method which, while tedious and painful in the adult, Broca has shown would be very brief, not exceeding four minutes, in the thinner and softer skull of childhood.

MIXED ANÆSTHESIA BY ETHER, MORPHINE, AND ATROPINE.

UNDER the above title, M. P. Aubert, of Lyons (*Lyon Médicale*, 14 Janvier, 1883), discusses the question of the conjoint administration of ether or chloroform, morphine and atropine. There are some very interesting subjects broached by Aubert, and the results of his experience are worthy of attentive consideration.

Those of our readers who have followed the history of anæsthesia, will recall the fact that Boston and Lyons, since the discovery of insensibility by inhalation of vapors, have remained loyal to ether as the best of the various agents hitherto brought forward for this purpose. Aubert, a representative of the Lyons sentiment, is not unmindful of the position of chloroform as an anæsthetic agent. His opinion is, therefore, the more valuable since he does not ignore the utility of other agents, although an advocate of ether. He also refers to the method of inducing the anæsthetic state, lately brought forward by M. Paul Bert, which consists in the administration, under pressure, of a mixture of oxygen and nitrous oxide; but this method, although strictly physiological, is objectionable because of the complexity of the apparatus required for its proper execution, and hence it is not feasible under the ordinary circumstances requiring the administration of an anæsthetic. To attain the maximum of safety with the anæsthetics now available, is the problem. How best to secure the safe administration of ether or chloroform is, therefore, the point for consideration. M. Aubert maintains that the best results are had from the method of "mixed anæsthesia." This is the outcome of his experience, and of the collective observation of the Lyons surgeons. He calls attention to the fact that so long ago as 1878, Brinon, one of his pupils, presented a prize thesis on the anæsthesia obtained by the combined action of chloroform and morphine. During the following year, M. Hortholès demonstrated that the combination of ether and morphine was superior in respect to the promptness of the anæsthetic action, and the relief to the after-vomiting, to chloroform alone, or to chloroform and morphine. In 1882, M. Morat communicated to the profession the result of experiences he had acquired, in conjunction with M. Dastre, regarding the combined action of an anæsthetic with the subcutaneous injection of morphine and atropine. The theoretical view which led to this combination may be stated as follows:

Vulpian has shown that the excitability of the pneumogastric is increased by anæsthetic agents—whence the vomiting, and sometimes cardiac arrest. Now, morphine, whilst it increases the anæsthetic action, does not to any considerable extent lessen the effect on the pneumogastric nerve; but atropine, by removing the inhibition exerted by the vagus, removes the most important source of danger.

The injection of the solution of the combined morphine and atropine is practised twenty or thirty minutes before the administration of the anæsthetic—usually ether. The ordinary dose of morphine is from $\frac{1}{12}$th to $\frac{1}{4}$th of a grain, and of atropine from $\frac{1}{180}$th to $\frac{1}{90}$th of a grain. Complete insensibility is obtained in from three to seven minutes. The assistants, says Dr. Aubert, have been much surprised to note the difference which exists between the method of mixed anæsthesia—so calm and silent—and the inhalation of ether alone, with its period of excitement, and the after-vomiting and depression.

The great superiority of ether over chloroform, as respects safety, is certain; but the unpleasant effects of the former, and the prolonged stage of excitement produced by its inhalation, constituted almost insuperable objections to its use. M. Aubert now maintains that the method of mixed anæsthesia obviates these objections, so that ether may be given with the same ease and satisfaction as chloroform.

In view of the recent sad examples, illustrating the danger of chloroform anæsthesia, it is the more desirable to be put in possession of a method which combines the facility of chloroform inhalations with the superior safety of ether. In the method of "mixed anæsthesia," this desirable result seems attained.

POISON IN THE KINDERGARTEN.

IT goes without saying that our children ought not to be poisoned. Yet in the Kindergarten, one very serious and mostly unsuspected danger has been brought very forcibly to our notice within the last few days, and we call instant and urgent attention to it.

An analysis of eighty-four samples of the paper used in the Kindergarten weaving, shows that *arsenic* is present to a considerable extent in a large number of the papers, and in eight of the samples to a very dangerous degree. The danger is especially great when we remember that young children not only handle them, but are very apt either to handle them with wet fingers or even very often to put them into their mouths and chew them. All of the eight worst papers were of the brightest and therefore the most attractive colors, three being greens, three reds, one blue, and one purple. They were all taken from the sample book of one Massachusetts firm, who

supply such papers in large quantities all over the land.

In one respect the firm is commendably honest. In their catalogue they openly state that many of the papers do contain arsenic, and that the brightest greens and reds cannot be made from other than arsenic colors. But they make light of the whole affair, saying, that "a child old enough to use the paper material should be too old to put such things in its mouth." As if *any* one under seven, at which age children leave the Kindergarten, were too old to put such things in its mouth. Moreover, they quaintly add, "we have yet to hear of a single Kindergarten pupil that has ever been injured by the use of the colored papers." Do they propose to go on furnishing papers known to be poisonous till they *do* hear of a child poisoned by them? Surely after the repeated exposure of the dangers of arsenic in wall papers it is little less than criminal to continue to make them, and least of all to make them for the use of children.

As to lead and other such poisons in colored papers the quantity that has to be eaten is so great, as compared with arsenic, that they are not seriously dangerous.

We hope that the State Board of Health of Massachusetts will investigate this matter. Indeed, it would be highly proper for the legislatures of our various States to make both the manufacture and the sale of such papers, whether for wall papers or other purposes, a penal offence.

PNEUMONIA.

BUHL, it will be remembered, makes the assertion that fibrinous or croupous pneumonia never terminates by passing into sclerosis of the lung. Two cases observed at the Tübingen policlinic by Jürgensen prove, however, that this mode of termination, although rare, does sometimes take place.

In some observations on the treatment of pneumonia, Prof. Jürgensen expresses himself as opposed to the administration of salicylic acid as an antipyretic, because it reduces the temperature so rapidly as to endanger collapse. Quinine is not open to this objection. He reserves digitalis for cases in which the action of the heart is irregular.

URÆMIA OF HEPATIC ORIGIN.

THE source of urea formation is by no means certainly known. Any facts bearing on this interesting question must, therefore, have a value determined by their relevancy. M. Débove has recently submitted a communication on this topic to the Medical Society of the Hospitals of Paris. As has been maintained by M. Brouardel, in most hepatic diseases a sensible decline takes place in the quantity of urea in the urine. It is held by most authors, that the diminution is in urea formation, rather than in the excretion of this substance, but M. Débove maintains the latter view. He has sought to maintain this position by comparative examinations of the blood, and of the urine. He has ascertained, he asserts, that in many chronic hepatic affections the quantity of urea in the urine is notably less, whilst in the blood it is increased. He holds, therefore, that there is a form of uræmia which is hepatic in origin. He explains these phenomena by assuming that the bile elements cause a retention of excrementitous matters in the blood.

DR. FORBES' ACQUITTAL.

SUCH wide publicity has been given to the arrest and indictment of Dr. Wm. S. Forbes, Demonstrator of Anatomy at the Jefferson Medical College, for conspiracy to rob Lebanon Cemetery, in this city, that it is only just that equal publicity should be given to the fact that twelve men, after a full hearing of the evidence, and in the face of a public feeling largely unfavorable to the accused, have unequivocally pronounced him "not guilty."

As every anatomist knows, the present law relating to anatomy is so ineffective, and the demand for subjects so pressing, so imperative, that, while refusing to take bodies from strangers (we would hardly say "buy," as did the learned judge in his charge, in spite of the fact that the law punishes "traffic" in human bodies), yet the medical schools *must* take "unclaimed bodies" from those whom they know, and who regularly bring such to them, without any inquiry as to where they came from, trusting to the integrity and law-abiding character of those who deliver them. As the learned judge said in his charge very properly, "for various reasons secrecy is maintained concerning them."

We earnestly hope that the new Anatomy Act may soon be passed, and with it we believe all temptation to violation of the law will disappear, for the supply of material will be abundant, and no anatomist will be put to the large expense, inexpressible annoyance, and terrible worry and strain to which our *confrère* has been needlessly subjected for the last three months. We congratulate him heartily on his vindication.

WOMEN AS PHARMACISTS.

WE are glad to see that at the late commencement of the College of Pharmacy, in this city, for the first time a woman had the degree in pharmacy conferred upon her. Of all the various branches of labor opening to women, none seems to us more promising than this, and we hope that many more may follow in her footsteps.

REVIEWS.

? Quiz-Compends ? Practice, Part I. By Daniel E. Hughes, M.D., etc. In two parts., pp. 105. Philadelphia: P. Blakiston, Son & Co., 1882.

The suggestive mark of interrogation may be interpreted to express the pertinent inquiry—*cui bono?* That the publishers will reap a greenback harvest there can be no doubt. That students will solace themselves with the pleasing notion, that here at last is an easy road to the acquisition of medical learning, may also be regarded as certain. But what of the author? We fear his attempt to smooth the rugged pathway to the doctorate will not redound to his own credit. When we come to examine his attempts to make plain the dark corners of medical knowledge, there arises a suspicion that his aspirations are beyond his powers—that his attempts to scale the heights are rendered abortive by insufficient legs. Let us examine his record. We need not go beyond the first page.

Organic disease is one "when located in some particular structure." It becomes "functional when the perverted process cannot be located." If a disease of the brain cannot be located, it becomes functional, therefore!!

A *diathesis* is a "hereditary predisposition to certain diseases." A predisposition cannot be acquired, must be inherited. On the next page we learn that "the *prodromes* are the earliest recognizable symptoms; when sudden in their onset, the disease is said to be *acute;* when less sudden, *sub-acute;* when gradual or slow, *chronic.*"

In this brief paragraph there are several errors. Prodromes are, as the term implies, forerunners or preliminary symptoms, and may be the same for many affections. Again, the terms acute, sub-acute, and chronic, apply not to the prodromes, but to the type of the case proper.

We might select a multitude of examples of erroneous definition and inaccurate statement. It is very unfortunate that medical students are to be induced to follow such a guide. If they are to depend on such a compend, it ought at least be accurate, and the profession has a right to demand that books of this kind be correct in statement, how deficient they may be in all other respects. Even if, however, quiz-compends are without defect in their own scope, they have no right to exist. The appearance of such a series as now announced is truly ominous, for it indicates the existence of a large number of students who are solely concerned to be able to pass the examination for the doctorate.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, February 27, 1883.

The President, T. M. Markoe, M.D., in the Chair.

ABSCESS IN THE LOWER PART OF THE FEMUR.

Dr. Lange presented a patient, twenty-eight years of age, who had had bone abscess. When thirteen years of age he was subject to osteitic affection of the femur, and during the next six years suffered from repeated exacerbations of the disease. The disease commenced with very severe pain which lasted for one year, but not until the end of two years did a sinus open and some pieces of bone make their exit. At the end of six years, no operation ever having been performed, all the sinuses closed and the patient remained apparently well until last August, when he again began to suffer from severe pains without apparent cause, especially at night, and when Dr. Lange saw him, in the beginning of October, he was very much reduced in strength, and presented that exhausted appearance and pale-gray complexion ordinarily seen with chronic bone abscess. On examination, the femur was found very much thickened in its lower half and somewhat thickened higher up. There was pain upon deep pressure in the region between the middle and the lower third of the thigh. The entire history of the case made it probable that central abscess of the bone existed, and he therefore, early in October, laid bare the bone, and bored into it in two places without finding pus, but on making a third opening pus discharged, and he then enlarged the opening and found quite an extensive abscess, the cavity of which seemed to be very narrow and made up of several lacunæ, one of which contained a small sequestrum. About half of the femur had to be chiselled open, the thickness of the wall of the abscess reaching in some spots nearly ½ inch. The immediate surrounding of the pus cavity consisted of soft cancellous tissue, permeated by granulations and small pus cavities. But, to that a very thick sclerotic bone substance followed. After the abscess had been evacuated and scraped out, the soft parts were closely stitched together by *étage* sutures; two bone drainage-tubes were inserted, and permanent antiseptic dressings were applied. During the next six weeks only four dressings were applied, and no accident took place, except necrosis of the superficial fascia in the upper part of the wound, and there still remained some small openings, which were simply superficial and had no connection whatever with the cavity of the bone. The femur upon the affected side was about an inch and a third longer than the other. Furthermore, the position of the knee was in hyperextension, and at the same time there was a slight amount of mobility in the joint greatly to the discomfort of the patient, because it gave to him a feeling of uncertainty in stepping. To remedy this to a certain extent, Dr. Lange had advised that an apparatus be worn which should fix the knee. During the past week pain had occurred again, but it differed in character from that from which the patient first suffered, and was shooting up and down the anterior aspect of the thigh. This pain had been relieved by the administration of quinine, and besides, the patient had a swollen spleen. At the time of the operation Dr. Lange opened the cavity of the knee-joint, which he found obliterated, but no unfavorable symptoms followed. An especially interesting feature in the case was the smooth healing of the bone cavity that followed complete sewing up of the soft parts, with the after-treatment adopted. The scar showed no depression, and was narrow on account of the first intention to the greatest extent.

OSTEOMYELITIS OF THE ILIUM.

Dr. Lange also presented a patient, sixteen years of age, whom he saw for the first time two years ago, and four weeks after the beginning of a severe illness, with the formation of a large abscess on the anterior aspect of the iliac fossa. The hip-joint was apparently not involved. He saw the patient in consultation with Dr. Hoeller, of this city, and made a number of incisions for the evacuation of pus. The case illustrated that spontaneous separation of the epiphyseal junction might occur suddenly, as in the next following week the patient's limb suddenly showed the deformity characteristic of fracture of the neck of the femur. A weight and pulley were then applied, and the great shortening which had occurred was for the greater part removed. Six months after the beginning of the abscess, Dr. Lange performed necrotomy of the ilium,

and removed twelve pieces of bone, mostly superficial, some of them central, especially in the upper part of the acetabulum. The patient made a comparatively speedy recovery. The position of the limb remained unsatisfactory, namely, in very great adduction. There was not complete anchylosis. The weight and pulley were applied, and the limb brought down, so that the difference in length between it and its fellow was not quite one inch, and with a slight corresponding elevation of the heel of the shoe on the affected side, the patient was able to walk very well. Since that time, the adduction had relapsed, and Dr. Lange thought it would be best to let it go on, and, after complete anchylosis had taken place, to make section of the bone for the correction of the deformity. He had had three cases of acute osteomyelitis of the ilium, in two of which there was separation of the epiphyseal junction at the neck of the femur. In one case he took particular care to avoid separation by applying a weight and pulley, and yet the accident occurred.

EXTIRPATION OF THE LOWER PART OF THE RECTUM, AND ALSO THE COCCYX.

DR. LANGE also presented a patient from whom he had removed the lower part of the rectum for cancer, and, to facilitate the operation, he had also removed the coccyx. The patient had been operated upon twice, the second time for recurring disease within the pelvis in the depth of the ischio-rectal fossa. At the present time he has several suspicious glands in the inguinal region. He presented the patient to illustrate the comparatively good functional result which followed the operation, namely, he was able to control the discharges from the bowels perfectly if the passages were consistent. Flatus escaped, however, without the control of the patient. The first operation was performed one year ago; the second operation was performed last October. The coccyx was removed at the first operation; at the second operation he removed the mucous membrane to some extent, on account of prolapsus. The removal of the coccyx at the first operation facilitated operative measures very much. There was not much obstruction of the bowel before the first operation was performed, and the patient was not aware of the existence of the disease until about six weeks previously; and yet he had extensive disease of the rectum. He had supposed that he was the subject of hemorrhoids, and had been treated for that affection. The explanation which Dr. Lange gave of the ability of the patient to control the discharge from the bowels was that the sphincter tertius maintained its function. It could be felt as a weak and soft somewhat incomplete closure immediately above the new external opening.

DR. L. A. STIMSON remarked that Dr. Lange's first case illustrated the importance of early attention to purulent disease within bone. He recalled a case in which he trephined the head of the tibia in a patient fourteen or fifteen years of age, who had been suffering for eighteen months with recurrent attacks of pain in the shaft of the tibia, and thickening of the upper and middle thirds of the bone had developed. He localized the seat of maximum pain, and trephined at that point, and pus was found in the medullary cavity after passing through a layer of compact bone one-fourth of an inch in thickness, and the operation was followed by rapid recovery, which had remained permanent to this date—nearly three years. At the time of the operation there was no sinus or discharge of pus, but the bone appeared somewhat thickened, and was sensitive, and the soft parts lying over it were thickened. On reaching the bone, the periosteum was found thickened, and an abscess opened which contained from half an ounce to an ounce of pus.

DR. POST remarked that in cases of persistent pain in the tibia confined to a limited space, a diagnosis of abscess was a pretty safe one to make.

DR. L. S. PILCHER then read a paper on

THE USE OF LIGATURES IN THE WOUNDS OF VEINS.

Dr. Benj. Travers, in his essay on *Wounds and Ligatures of Veins*, which was published in 1811, seems to have been the first to draw special attention to the dangers attending injuries of veins. He speaks of the "fatal catalogue of tied veins," and says that he has observed something like that superstitious alarm which is excited by events that we do not expect and cannot explain, when such a catalogue is compared with the generally successful cases of tied arteries. Mr. Travers says that it has been shown "that the inflammation of the interior tunic of a vein sometimes follows a puncture, sometimes a division, a ligature encircling the tube, or including only a part of it, or arises spontaneously from an inflamed surface, of which the veins form a part." He ascribes to John Hunter the credit of having first distinctly pointed out the liability of the interior tunic of veins to inflammation, and exclaims that it is most extraordinary "that this alarming and often fatal inflammation of the inner coat of veins should so long have escaped the notice of the profession." The language of Dr. Hunter (quoted by Mr. Travers from the *Medical and Chirurgical Transactions*, vol. i. pp. 18, 19) is, "I have found in all violent inflammations of the cellular membrane, whether spontaneous or in consequence of accident, as in compound fracture, or of surgical operation, as in the wound of an extremity, the coats of the larger veins passing through the inflamed part become also considerably inflamed, and that their inner surfaces take on the adhesive, suppurative, and ulcerative inflammations; for in such inflammations, I have found in many places of the veins adhesions, in others matter, and in others ulceration." "I have found them [these appearances] in the bodies of those who have died from amputations, compound fractures, and mortification."

Mr. Travers, in this essay, remarked the indisposition to inflame manifested by the inner tunic of veins as a rule, having himself observed that, even after ligation, there was no blush upon the inner tunic, much less any sign of adhesive inflammation, or thickening of the proper coats of the vein, or agglutination of the contiguous folds (p. 201), so that the process of healing and of division by ulceration seem to him to be conducted without any manifestation of inflammatory action in the interior tunic. He thought, however, that this was not inconsistent with a liability to inordinate and excessive inflammation under adequate excitement.

This opinion as to the indisposition of the inner tunic to inflame has become more positively expressed by recent writers. Nicaise, in his thesis "On Wounds and on Ligation of Veins" (Paris, 1872), p. 74, states that, though Hunter, and after him Ribes, Gendrin, and others, considered phlebitis as an inflammation of the internal tunic, numerous observations since their time have demonstrated that primary inflammation of that membrane is very rare, if, indeed, it exists. He does not enter into any discussion of the subject, but contents himself with saying that most frequently inflammation begins in the cellular tunic, and thence may spread to the middle and involve also the internal tunic. He quotes Trousseau and Rigot (from the *Arch. Gén. de Méd.*, 1827), as saying that, "Every year we see patients succumb to phlebitis supervening upon phlebetomy. We are far from denying the frequency of the accidents which follow bleeding; but too often there has been taken for an inflammation of the vein what was only inflammation of its cellular sheath." A kind of periphlebitis being the real malady. Still

more positively does Mr. Callender, in the article on diseases of veins—Holme's *System of Surgery*—claim that primary inflammation of the inner tunic of veins is never met with, and that in all cases we have to do with either progressive coagulation of blood within veins and its sequelæ, or with diffuse phlegmonous inflammation of their connective-tissue sheaths; thrombosis and periphlebitis being thus substituted in surgical nomenclature for phlebitis. Diffuse periphlebitis, according to this author, cannot occur in a patient in a fair condition of health, and when it does occur after puncture or division of a vein, it is not a consequence of the application of a ligature, for, whether the vessel be tied or not, this inflammation may supervene.

The changes of views which appear from these brief historical references, to have taken place as to the liabilities to inflammation inherent in veins, have been attended with corresponding changes in the character of the surgical interference to which they are subjected. To a period during which there was entire absence of apprehension of danger, so that, to use the language of Travers, they were attacked with singular rudeness, pricking, cutting, tying, and burning them, without ever adverting to any other than the mechanical effects of such operations upon the diseases for which they were instituted, there succeeded years during which they came to be considered as especially intolerant of interference, and prone to the development of unexpected and uncontrollable complications. To this has now succeeded another period in which any special vulnerability in veins is not admitted, and a tendency to return to unrestricted attacks is manifest.

For the purpose of eliciting the experience and opinions of the surgeons of to-day, on the important question of the hazards of surgical interference with veins, I took up one year ago, in a paper which I read before the Philadelphia County Medical Society, the subject of the ligature of large venous trunks. It will be remembered that Dr. S. W. Gross, of Philadelphia, in a paper published by him in the *American Journal of the Medical Sciences* in 1867, upon wounds of the internal jugular vein and their treatment, reached the conclusion that the dangers of ligation of that vessel had been greatly exaggerated, as not a single example had been found by him, in which ligation had been followed by diffused phlebitis. Embodied in that paper was also a summary of the teachings of prominent surgical authors of the present century up to that date, as to venous ligation in general, from which it appears that while a numerical majority teach that its risks have been greatly exaggerated, yet a sufficiently large number, including the names of Roux, Lisfranc, Langenbeck, Miller, Erichsen, and Pirogoff, speak of it as being attended with great danger, and to be avoided by all possible means.

I called attention also to the additional source of danger which had been claimed to exist in the denudation and contusion of veins. Dr. Gross, in his paper, had quoted the observations of Broca, who, in his treatise on aneurisms (*Des Aneurysmes et de leur Traitement*, p. 478, Paris 1856), describes inflammation of the accompanying vein denuded, perhaps bruised in exposing an artery for the purpose of ligation, as one of the possible complications of such operations. Also, two cases reported by Langenbeck (in *Archiv für Klinische Chirurg.*, 1860, t. i.), in which thrombosis followed, with a fatal result in one of the cases; a denudation of veins occurring in the course of the removal of tumors; also, observations of a similar nature by Post and J. C. Warren.

Nicaise, in his thesis already referred to, quotes these observations also, and adds that Ollier, of Lyons, has several times observed this accident, so that he has formed the opinion that extensive denudation of a large vein is more dangerous than ligation; and that where, after such denudation immediate union is not obtained, when the flaps that cover the veins slough; when, in a word, the veins remain exposed at the bottom of the wound, all the accidents of an extensive and progressive thrombosis are likely to occur. In three instances Ollier had seen death follow in from eighteen to thirty-six hours after the beginning of the thrombosis. Happily, however, says Nicaise, denudation does not inevitably involve accidents so grave as those noted by Ollier; most frequently it is followed by no complication. Nicaise also quotes the opinion of Weber (Pitha und Billroth, *Handbuch der Allgemeinen und Speciellen Chirurgie*), that contusions of veins are more likely to be followed by thrombosis and suppurative periphlebitis than are pricks and lateral wounds.

In the discussion[1] that followed the reading of my paper, Prof. Henry H. Smith stated that he was not aware that any doubt existed among surgeons of the present day as to the advisability of ligating veins, although he was of the opinion that a diseased vein, *e. g.*, varicose, would be apt to give trouble under conditions in which a healthy vein would do well; citing a case in which varicose veins of the leg were tied, and death ensued in five days.

Prof. Samuel D. Gross said that he had long been in the habit of ligating veins, and early in his professional life was impressed with the fact that the fear of such ligations was unfounded. He was opposed to lateral ligation, and thought it always best to tie the vein in its continuity. Varicose veins he would not ligate, nor would he excise an exposed vein, unless it could not be avoided.

Prof. S. W. Gross stated that he was now cognizant of sixty cases in which the internal jugular vein had been tied; forty-seven of these were examples of ordinary deligation, of which one terminated in death by thrombosis. Thirteen were instances of the application of a lateral ligature, of which four proved fatal from secondary hemorrhage. The freedom from hemorrhage after the ordinary procedure, and the occurrence of fatal bleeding in more than one-third of all cases after the lateral ligature, was a sufficient ground for its exclusion from practice. He believed that veins may be ligated with as much confidence as arteries.

Dr. Packard stated that, in his experience, whether in cases under his own care or in the hands of other surgeons, ligation of veins had been attended by no bad results.

Dr. Hunter stated that Dr. Agnew had ligated the internal jugular vein at its point of emergence from the skull, the ligature coming away at the end of the second week without unfavorable symptoms.

Dr. Blackwood had seen during the war many cases of gunshot wounds of the vessels of the neck; whenever lateral ligation had been used, in the cases in whose after-history he had been able to follow, a fatal result from secondary hemorrhage had ensued. He had no fear in ligating veins, though he agreed that diseased veins do not bear ligation like healthy ones.

Dr. Nancrede reported a case in which he had been compelled to keep the internal jugular vein exposed for a long time, in an operation which was followed by prolonged suppuration, during which the vein was kept bathed in pus, without injury to it. He never hesitated to tie veins in the course of operations.

Dr. Allis had applied a lateral ligature to a wounded internal jugular vein, and had obtained rapid and permanent recovery. Dr. Parkes, of Chicago, had

[1] See Philadelphia Medical Times, 1882, p. 664.

seen lateral ligation used in three cases of wounds of the internal jugular vein, with recovery in each case, while in one case, after complete ligation, death was occasioned in thirty-six hours from thrombosis.

DR. KEEN could not agree with previous speakers as to the inadvisability of operating upon diseased veins. In varicose conditions he had several times exposed and ligated the veins at points one inch or more apart, and exsected the intervening portion by the antiseptic method, and with excellent results. In his opinion, the ligation of varicose veins by the catgut ligature was the best treatment.

It will be seen that the points upon which discussion was elicited involved the subjects of the safety of ligation in general, the propriety of the application of a lateral ligature in certain cases, and the effects of exposure and denudation of veins. Despite the freedom from disaster, which had characterized the large experience of the eminent surgeons who took part in this discussion, and which thus far has likewise been enjoyed by myself, I am not quite prepared to dismiss, as without foundation, the opinions of the many other eminent observers who declare that surgical interference with veins does involve peculiar dangers. While so strongly expressed an opinion as that of Chassaignac that "ligation is one of the most dangerous operations of surgery" (*Traité Clin. et Prat. de l' Operat. Chirurg.*, t. 1.), may not appear to be justified, or even that of Erichsen, that the application of a ligature to a vein "should, if possible, always be avoided" (*Science and Art of Surgery*, 1878, vol. i. p. 278), it is still undeniable that there are special hazards that attend the surgery of the veins. "The fatal catalogue of tied veins," referred to by Travers, the yearly deaths from inflammatory complications following phlebotomy, admitted by Trosseau, and the fatal cases of thrombosis, reported by Ollier, remain each as types of a distinct class, to which fresh examples are from time to time being added, of dangers that are peculiar to veins, and which ought, even in this day, to receive due attention from surgeons. The direction of the blood current in the veins towards the heart through continually widening channels, and the favorable arrangement of the connective-tissue sheaths of the veins for the propagation along the course of the veins, as in lines of least resistance, of spreading suppurative inflammation, constitute the conditions which, by their combination, favor the production of disastrous complications after wounds of these vessels.

The more accurate knowledge which recent research has given us of the etiology and pathology of these complications, has made more emphatic the truth that in addition to the predisposing causes, both local and constitutional, that may exist, the introduction of a continuously active irritant from without through a wound is essential to the establishment and extension of the morbid processes. Here we venture upon a field which is yearly becoming less and less debatable; that is, the agency of micro-organisms in the production of spreading inflammation. The differences in the intensity of the results of these agents in different cases seems to be due to differences in the resisting power of the tissues to which they gain access. The presence of defective resisting power gives a ready and sufficient explanation why, in persons depressed and enfeebled from any cause, a wounded vein should be more likely to give trouble than in the robust and vigorous. Also, it explains why the nutritive defects in the tissues that lie about varicose veins should be sufficient to render operations upon such veins extra hazardous. An important consideration in this connection also is that, in most instances, the resisting power of the tissues, though diminished, would still be sufficient to resist attack and accomplish repair without serious complication, if they were not submitted to extensive and repeated traumatism. Thus from the point of view of the relation of micro-organisms to wound disturbances, the conclusion forces itself upon the conviction of the observant surgeon that in all cases care should be taken that a minimum of traumatism should be inflicted upon veins and their ensheathing connective tissue; particularly when adequate measures to prevent the access of noxious micro-organisms are impracticable, does the importance of fostering the natural resisting power of the tissue demand recognition.

If the tissue conditions which attend varicose veins be taken as an example of a vulnerable tissue, it is easy to understand why so frequently disastrous consequences have followed operations upon them conducted without antiseptic precautions; and why, with such precautions, such disasters rarely, if ever, occur. In such procedures as the strangling of a varicose vein between an unirritating metallic pin inserted behind it, and a compress laid over it upon the surface of the skin, or the subcutaneous injection into the neighborhood of the vein of a substance capable of exciting a local adhesive inflammation in the tissues reached by it, the two opposite conditions of wound treatment are exemplified. In the one, no protection from hurtful atmospheric constituents, but a minimum of local tissue irritation; in the other, a maximum of local tissue traumatism, with exclusion of atmospheric germs. It is to be expected that excellent results should attend either method, though both are imperfect in their conception, and both more hazardous than methods in which the two conditions are combined; that is, methods by which both exclusion of noxious micro-organisms is secured, and a minimum of local tissue traumatism is produced.

The question of the relations of micro-organisms to the effects likely to follow involves, in addition to these differences in local tissue, vulnerability exemplified in the case of varicose as compared with sound veins, and the different constitutional susceptibility possessed by different individuals to the effects of micro-organisms: as Ogston (*British Med. Journal*, March 12, 1881), when injecting micrococcus pus into the tissue of mice, found that, though the same dose was injected into each of a number of mice of the same litter, the effects greatly varied—one, perhaps the largest and strongest, escaping unscathed or with but slight illness; in others, abscess developing; in some, necrosis; and in one, perhaps the smallest or most weakly, death from septicæmia. So also with the same amount of traumatism and the same exposure to the access of micro-organisms in operations involving veins. The most diverse effects may result in different individuals, though in all, whatever the perturbation in the normal process of repair may have been present, the cause has been the same—poisoning by micro-organisms.

I will take the liberty of citing, as well as illustrating, the most grave consequences of poisoning by micro-organisms following operations upon veins. In the case of operation for cure of an arterio-venous aneurism which was reported to this Society, April 26, 1881, by Dr. E. L. Keyes (*Virginia Med. Monthly*, December, 1881), the patient was described as having been anæmic, and possessed of a low degree of vitality. The operation, at Bellevue Hospital, was difficult and prolonged; at its close, there was a ligature upon the perineal, upon the posterior tibial, and upon the popliteal, and upon one other vein, while the aperture of the anterior tibial vein was occluded by a sponge saturated with a solution of subsulphate of iron. The patient rallied slowly from the ether. The wound did not granulate, but assumed first a dry pink, then a moist gray appearance, with some colored serum

shortly before death. Forty-two hours after the operation there was a slight chill, followed by a condition of torpor, physical depression without delirium, terminating in death sixteen hours later. Just before death, the temperature was found to be 105.25° F.

What was the source of the poison that so speedily overwhelmed this patient, and prevented even local reparative effort? No microscopical examination of the tissue of the wound site in this case are recorded; but observations of similar cases by other observers (Ogston, *loc. cit.*, and also *Journal of Anatomy and Physiology*, vol. xvii. p. 49) and experiments upon animals have demonstrated that in such cases the wound tissues are infiltrated by enormous and appalling growths of micrococci. The poisonous ichor or ptomaine, the chemical resultant of the decomposition induced by the proliferating micro-organisms, is produced in quantities measured only by the activity of the growths of the micro-organisms, and is absorbed rapidly into the blood, and in such amount that but a few hours are needed for such a degree of blood-poisoning to be effected that death is the result.

The case in question is seen to have had in an unusual degree all the conditions needful for the development of the greatest activity of invading micro-organisms—general resisting power at a low ebb, local tissue resisting power undermined by previous disease, traumatism great and prolonged, a hospital atmosphere likely to contain active germs. It is obvious that in other cases in which less favoring conditions exist, every gradation, both of the local and general toxic manifestation may be produced, so that in slight irritation and transient fever, in phlegmonous inflammations, early bounded by the formation of a wall of granulation tissue, in diffuse inflammation with spreading gangrene and advancing venous thrombosis, as well as in the instance in which profound and rapid general intoxication is produced with but slight local symptoms, we have an expression of the result of the same disturbing agent. While it is true that the development of these effects does not necessarily depend upon the presence of veins in the wounds thus attacked, yet a frequent connection between veins and the more severe grades of this tissue poisoning, poisoning results from the readiness with which the connective tissue which ensheathes the veins permits the progressive invasion of micro-organisms, and from the fact that the resulting periphlebitis determines the formation of coagula in the involved vein, which, in their turn, are likely to be speedily invaded by micro-organisms and become converted into poison dépôts from which ptomaines, pus, and emboli are discharged directly into the circulation.

The question whether the application of a ligature to a vein is in itself the source of any additional hazard in any given case becomes perceptible of a more definite answer in the light of the more definite knowledge to which we have attained as to the pathology of the disturbances which complicate wounds. It has been seen to how different a conclusion a simple appeal to experience has led different observers; these conclusions varying from the extreme presented by Gross, that "the danger of ligating veins is in great degree, if not entirely, unfounded;" to that presented by Chassaignac, that "ligation is one of the most dangerous operations of surgery." A more satisfactory result will be reached by an analysis of the particular conditions which the presence of a ligature upon a vein introduces into a wound, and by a consideration of the effects of such conditions upon its repair.

The introduction of the antiseptic animal ligature has modified so greatly the conditions which attend a ligature, in those cases in which it is used, that a discussion of the effects of the ligature demands a separate consideration of the simple unprepared thread, and of the antiseptic animal ligature.

The doctrine that the tunics of a vein possess a special intolerance that renders them liable to destructive inflammation more quickly, and upon less irritation than other tissues, has received abundant refutation, and deserves mention simply as a matter of historical interest.

The effects of the mere constriction of the vessel by the ligature does not introduce new dangers into the wound. What these effects are, the use of antiseptic ligatures has enabled us to determine, and their discussion will be in order, more particularly in connection with the consideration of the effects of such ligatures. It is, therefore, among the indirect effects of a ligature that conditions of importance, if there be any, are to be found. These indirect effects are purely those produced by the prolonged sojourn of the ligature in the tissues. Whenever the traditional ligature is applied, the constricting thread is an irritating foreign body in the wound, and invariably excites along its track an inflammation which persists until its removal is permitted by the division, by ulceration, of the walls ot the constricted vein, a period of time extending upon an average from one to two weeks, according to the size of the vein. By preventing union by first intention the ligature favors the entrance and development of atmospheric germs during the entire time that it keeps the wound open, and saturated with the secretions of the suppurating sinus which it creates, it becomes the best of mediums for transmitting micro-organisms to the deepest part of the wound. The irritation of its presence puts an additional strain upon the resisting power of the tissues among which it lies, and to this extent lessens their ability to resist the invasion of micro-organisms that may at any time find access to them.

The result of a failure of the tissues to resist such invasion of micro-organisms has already been dwelt upon, and the relation of cause and effect, which they bear to diffuse periphlebitis and to septicæmia shown.

The conditions thus enumerated, which attend the presence of an ordinary ligature, when viewed in the light of present knowledge as to the agencies by which wound disturbances are caused, certainly justify a dread of ligation as a hæmostatic agent in venous hemorrhage, and makes more emphatic the cautions as to its use. That in the great majority of cases the amount of disturbance resulting from the ligature should be limited to a circumscribed inflammation, which simply mats together the tissues adjacent to the ligature, is but another evidence of the extent of the natural resisting power inherent in healthy living tissues. It is in those cases in which defects of resisting power exists, as notably in tissues whose nutrition has been interfered with by the varicosity of their veins, that the full effects of the conditions determined by the ligature would be developed.

But these considerations as to the sources of wound disturbance and their relation to serious complications after vein wounds, show the importance of eliminating them, not only in cases where veins already diseased exist, but also in all cases in which vein wounds demand special means for the control of hemorrhage. The importance of protecting such wounds from further irritation, and from becoming the seat of multiplying micro-organism, makes of great importance the search for a substitute for the ordinary ligature.

The acu-pressure of Simpson and the forci-pressure of Pean, both present great advantages, as methods for controlling venous hemorrhage, over the common ligature, and few conditions will be found in which one or other of them may not be substituted for the ligature. The retention of the compressing needle, or forceps,

is rarely necessary for a longer period than a few hours. Their smooth metallic surfaces do not irritate the wound, and their early withdrawal removes any obstacle to union by first intention that they might possibly have caused during their residence in the wound. In my paper of last year, already referred to, I reported a case in which permanent closure of a lateral wound in the internal jugular vein was accomplished by the application of the hæmostatic forceps and its retention for a little more than twenty-four hours. In most cases, as in wounds of veins in the axilla, or in the neck, in operations in those regions I have been able to remove them in a much shorter time.

In dealing with wounded veins, as acu-pressure needles and hæmostatic forceps excel the ordinary ligatures, so they, in turn, are excelled by the animal ligature and the antiseptic methods by which, with a perfect hæmostatic, easily and universally applicable, that provokes no irritation by its presence in the tissues, and that is spontaneously removed by absorption when no longer needed, security is also guaranteed against the access of micro-organisms that might disturb repair. By the use of the antiseptic animal ligature it becomes possible to avoid the sources of disturbance that have thus far been recognized in wounds involving veins, and thus inflammatory and septicæmic complications almost completely vanish from the phenomena that attend the ligation of veins.

But one possible objection presents itself to the use of an unirritating absorbable thread, viz., that its application may not be sufficient to produce the effusion of the amount of plastic material necessary for securing the permanent adhesion of the vein walls at the point of constriction. Such an objection, however, has not thus far been supported by clinical experience. In connection with this experience, an experimental inquiry into the method by which obliteration of a vein is accomplished without the aid of a thrombus, or of an irritating ligature would be of importance. For the purpose of such a study I made a number of experiments during the past year upon goats; these experiments included three ligations of the internal jugular vein, and two of the femoral vein; I was assisted in them by my friends Drs. Fowler, J. H. Hunt, and J. E. Pilcher. Antiseptic catgut was used as the ligature in each, and the operation was done with antiseptic precautions; union by first intention of the operation wound was secured in each instance. As the result of these operations, I secured specimens illustrating the condition of repair upon the second, fourth, ninth, fourteenth, and twenty-fourth days after ligation. These specimens were prepared for microscopical examination by Dr. Hunt, who made sections of the frozen fresh specimens, which were then stained with hæmotoxylin and eosine, and mounted in damar. In the interpretation of these preparations I have been able to obtain the skilled opinion of Dr. E. O. Shakespeare, of Philadelphia, who finds that in them the tissue cells of the tunica interna are seen to have undergone marked proliferation; the activity of this proliferation being greater as the point where the vein walls are constricted and approximated by the ligature is approached. By the accumulation and confluence of the mass of cells in the cul-de-sac formed by the vein constriction, obliteration of the lumen of the vein is accomplished; this obliteration being perfected and made permanent by the subsequent extension of capillaries into it, and its transformation into connective tissue. Reference to these experiments, together with diagrams illustrating this proliferation of the tunica interna will be found in a report of the lecture of Dr. Shakespeare on inflammation in the bloodvessels, delivered before the College of Physicians of Philadelphia, 1882, and published in THE MEDICAL NEWS, May 20, 1882, p. 539.

In none of these experiments did a thrombus form on either side of the ligature, except in one case, in which, after having applied one ligature, I applied a second one to the swollen vein above, a little more than an inch distant. The part of the vein between the two ligatures having been left filled with blood, I thus obtained a thrombus. This specimen was removed on the ninth day. It seemed to illustrate the conditions of repair in the absence of a clot on the one side of the ligature, and in its presence on the other side. On this latter side, the clot has simply seemed as an unirritating injecting material, by which the vein is distended, and the study of the conditions presented by the vessel is facilitated, without otherwise modifying the character of the reparative process. The clot plays here, as in any other wound in which blood has been effused, and in which it has been protected from the access of destructive micro-organisms, simply the part of an unirritating foreign substance mechanically distending the parts among which it is diffused, until it shall be invaded and appropriated by active cells from the adjacent tissue.

The ligatures still remained unchanged in all the specimens, the chromic gut, which was used in the first two experiments, and the long-kept carbolized gut (three years in carbolized oil), which was used in the last three experiments, not being readily acted upon by the tissues. Though the ligatures were thus made less absorbable, the tissues in which they were embedded showed no irritation from their presence.

A plain conclusion from these considerations as to the character of the process, determined by the application of a ligature to a vein, is that the obliteration of the lumen of the vessel is a secondary effect of reparative changes which have as their first object the restoration of functions in parts whose nutrition has been disturbed by the original application of the ligature. The simple fact that the agent which has disturbed the nutrition of the tunica interna, and provoked a more active metamorphosis and proliferation of its cell elements, has at the same time held the vein walls in coaptation until the confluence of the plastic material from the constricted vein walls has become sufficient in amount and tenacity to permanently unite them together. Essentially, the process is that of the formation of a cicatrix, and in its course the ligature plays the same part as does the suture in ordinary wounds, that of maintaining coaptation of the wounded structures until firm adhesion is secured. We see in this also the same process as that by which a simple lateral slit in the vein wall may be repaired without obstruction to the current of blood through the vessel, the edges of the slit themselves furnishing the material for its repair, the amount of which material, if only further irritation or traumatism be withheld, being strictly limited to the reparative needs of the injured structures.

These conclusions as to the process of repair after ligation of veins with unirritating ligatures find an important practical application in the consideration of the propriety of substituting a lateral ligature, or a lateral suture for ligatures encircling the entire vessel in the treatment of wounds involving but a portion of the side walls of a great vein.

It will be remembered how positive was the condemnation of the lateral ligature expressed both by Prof. S. D. Gross and by Prof. S. W. Gross in the Philadelphia discussion. I find that Malgaigne also (*Médicine Operatoire*, ed. 1881, p. 114) strongly condemns it, saying that "the lateral ligature will be an operation forever to be condemned," and that "for very extensive wounds of venous trunks, where compression is insufficient, the *only* resource is the ordinary ligature." Malgaigne's objection, however, was

founded on the erroneous idea that permanent hæmostasis after a vein wound dependent upon the formation of a clot sufficient to occlude the entire lumen of the wounded vessel, and that, inasmuch as the lateral ligatures in some cases might fail to provoke the formation of such a clot, in such cases where the ligature came away, secondary hemorrhage would be inevitable.

The objection of Prof. Gross is based upon the statistical statement, that of thirteen instances in which the lateral ligature had been applied, four proved fatal from secondary hemorrhage; a source of danger of rare occurrence when a vein is ligated in its continuity. Such a record of disasters, in his opinion, outweighs any advantages that might be supposed to be gained by lateral ligatures, and make its use justifiable.

It is to be borne in mind, however, that this record of disasters is a record of results from the use of the ordinary ligature. Reference to what has already been said as to the conditions which the use of such ligatures introduces into the repair of a wounded vein will be found to give ample explanation of the frequency of secondary hemorrhage after its use as a lateral ligature. The introduction of the antiseptic animal ligature, however, which may be cut short, and over which speedy union by first intention of the wound may be secured, places the subject of lateral ligature upon an entirely different basis. The tissues of the puckered side-wall of the vein, where they are grasped by the ligature, are placed in the same condition as that already described as characterizing veins ligated in their continuity. No thrombosis is required, nor formed by its insufficiency or its disintegration to become a source of danger. There is no ulcerative process to extend unduly and to leave an opening in the vein wall when the ligature comes away. That the process of the formation and complete organization of the plastic material that fills in and effaces the irregularity produced by the application of the ligature should proceed undisturbed to its conclusion, demands simply that the general precautions for securing wound repairs are observed. The ligature acts as an unirritating reinforcement that prevents the rupture of this new tissue during the yielding period of its history, and itself finally is disintegrated and is removed in the ordinary tissue changes of the part. Practised with the antiseptic animal ligature, lateral ligature, therefore, promises to be a justifiable and valuable means of treatment in wounds of the lateral walls of veins.

Lateral suture suggests itself as a resource in long linear wounds of the side walls of large veins. It would be simply a modification of the lateral ligature, and the same considerations would be applicable to it. I believe it to be practicable, and can conceive of conditions in which it would be a resource of great value.

DR. POST remarked concerning the ligation of veins in stumps after amputation, that he had been accustomed to do so without hesitation, and had not known any injurious consequences to follow. He had had one case in which he tied the primitive carotid artery for a large teleangiectasis involving one side of the face. The patient died with symptoms of pyæmia; although the jugular vein was not exposed, there was found at the autopsy thrombosis of that vessel and embolic inflammation of the lung. The vein also contained a phlebolite.

He had also met with one fatal case of phlebitis following the use of pins in the treatment of varicose veins of the thigh.

DR. GERSTER had applied the lateral ligature to the internal jugular vein in a case of multiple lymphoma of the neck. A row of catgut ligatures were applied to a longitudinal slit, and primary union followed the operation. He had also ligated the internal jugular vein in the course of exsection of tumors of the neck in four instances, in some of these cases he applied simply a double ligature. In two instances, however, he was obliged to exsect considerable portions of the vessel, and in one case, death followed exsection very shortly. The case was one of those where it is impossible to determine whether death was caused by incipient acute septicæmia or shock. A post-mortem was made, but it did not reveal any positive evidence as to the cause of death. The central portion of the vein did not show any septic changes which could serve to explain the termination of the case.

In one case he had exsected a very large venous plexus, situated near the scroto-femoral fold, mainly on the inner surface of the thigh in a powerful young baker, who was prevented from attending to his daily business on account of the severe pain which the growth produced. It was a convolution of varicose veins, some of them very large, covering an area of about ten square inches. In that case he removed the entire mass, and proceeded as in the exsection of a very vascular tumor, applying double ligatures, about sixty in number, and cutting the vessels between them. Some of the branches of the vessels penetrated through the fascia into the muscular structure, and were removed with portions of connective tissue and of muscle *en masse*. Union by first intention occurred in this case, and no further trouble was experienced. The chrominized catgut ligature was employed.

DR. LANGE referred to a case already reported to the Society, in which he applied the lateral ligature to the internal jugular vein, accidentally opened in the attempt to tie the common carotid artery for secondary hemorrhage. In that instance air entered the vein. The ligature used was antiseptic silk, and recovery took place, and he subsequently presented the patient to the Society.

VESICAL CALCULUS WITH A PIECE OF SILVER WIRE FOR A NUCLEUS.

DR. J. C. HUTCHISON presented a vesical calculus which he removed from a boy fifteen years of age, upon whom he operated ten years ago for stone in the bladder. The first operation was that of median lithotomy, in which he wounded the rectum, and a rectal fistula followed, and continued up to the time of the second operation. He made several attempts to close the fistula, twice by inserting silver wire sutures, two or three times by touching the margins of the fistulous opening with nitric acid, but in all instances unsuccessfully. The last attempt to close the fistula by sutures was about a year and a half ago. The case was left under the charge of the house surgeon, who was requested to remove the sutures at a certain time, and he did so. The boy, however, was never comfortable after the operation, but always complained more or less of pain in the bladder. The urine continued to pass through the rectum, but the opening was very small. On the first of February last, Dr. Hutchison examined the bladder very carefully with the sound, symptoms of stone having presented themselves, and detected a calculus. On the following day he performed the medio-bilateral operation, and found the stone adherent to the posterior part of the bladder so firmly that he was unable to detach it with his finger, but by taking a piece of flexible wire and making a loop he was able to remove it. On examining it he found the nucleus was a piece of silver wire.

The interesting features in the case were, first, the wound of the rectum, not a common accident in lithotomy. Second, the difficulty in closing the fistula. Third, the accident of dropping a suture into the bladder, which formed the nucleus of the calculus. Fourth, the difficulty of detaching the stone from the

wall of the bladder at the time of the operation. After the last operation the perineal wound was kept open for twelve days, and the edges of the fistula were again touched with nitric acid. The wound was kept open by introducing a catheter through it, allowing the tip of the instrument to remain just in the neck of the bladder, pushing it forward occasionally to withdraw the urine. This was done with the hope that the fistula might close, and he was of the opinion that union had taken place.

DR. POST mentioned that Dr. Kearny Rogers, operated a large number of times for vesical calculus, and frequently wounded the rectum, but no bad results followed in any of his cases.

DR. BRIDDON remarked that wounding the rectum was not so infrequent as was generally supposed, it had occurred once to him in eighteen lithotomies.

The PRESIDENT remarked that wounding of the rectum with the median operation was quite unusual. He had operated by the median operation some thirty-four or thirty-six times, and had never had an accident of that kind

DR. HUTCHISON remarked that this was the only case in which he had performed the median operation.

OSTEO-SARCOMA OF THE THIGH.

DR. POST remarked that an interesting feature in the case which he reported at the last meeting was that a week after the operation there was an active pulsation in the femoral artery from the groin downwards to the point where the vessel bifurcates. Below that point, the patient's limb being very thin, he was able to trace the vessel distinctly as a hard cord, nearly as large as the little finger, and evidently filled with a coagulum.

RHODE ISLAND MEDICAL SOCIETY.

Quarterly Meeting, March 13, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE Society met in Lyceum Hall, Providence, March 15th, the PRESIDENT, DR. JOB KENYON, in the chair.

The SECRETARY, DR. G. D. HERSEY, read the records of the December meeting, which were approved.

The Chair appointed Drs. Anthony, Saunders, and White, a committee to nominate

DELEGATES TO THE AMERICAN MEDICAL ASSOCIATION,

and upon the recommendation of this committee, the following gentlemen were elected delegates:

Drs. Job Kenyon, O. C. Wiggin, H. G. Miller, C. W. Parsons, C. B. Mathewson, Geo. H. Kenyon, G. D. Hersey, W. E. Anthony, A. A. Saunders, F. H. Rankin, S. W. Francis, D. H. Batchelder, G. W. Stanley, S. Hunt, H. G. Pomroy, S. B. Church, W. J. Burge, W. S. Bowen.

The President and Secretary were empowered to fill any vacancies that might occur.

DR. G. TABOR SWARTS read a paper giving the results of his investigations of the recent

EPIDEMIC OF TYPHOID FEVER IN PROVIDENCE.

He stated that out of five hundred reported cases he had thus far investigated two hundred, and proposed bringing up the subject again at a subsequent writing. Regarding the two hundred cases looked into, he observed as follows: A few cases were reported in September, 1882, a larger number through October, and the greatest number late in October, and the early part of November—Nov. 1st nineteen cases were reported in a single day. Of the two hundred patients, the occupations were these: sixty-two were scholars or teachers; eighty-five were in sedentary or indoor work; twenty-seven were in pursuits necessitating a constant change of temperature; nine were engaged entirely out of doors; seventeen not ascertained.

Sex.	Color.	Age.
111 males.	195 white.	1 to 5 years—15 cases.
89 females.	5 colored.	6 " 10 " —32 "
		11 " 20 " —81 "
		21 " 30 " —44 "
		31 " 40 " —17 "
		41 " 50 " — 6 "
		51 " 60 " — 5 "

In seeking for possible local causes of the disease, he had noted the following: In twenty-three instances the cellars were damp; in many localities garbage was found; in twenty-five per cent. of the cases *well* water alone was used by the family for drinking and cooking; and in five per cent. tank or cistern water. In many instances it was suspected that the domestics were in the habit of using water from the *hot* water faucets for culinary purposes, which may be dangerous if the plumbing of the *tank* that supplies the hot-water reservoir is defective. In seventy nine houses iron sinks, having an unwholesome odor, were found, there being a lack of proper trapping. Nothing suspicious was found relative to the milk and ice used in the families. On the whole, fair sanitary conditions were found in thirty-two per cent. of the cases, and unsanitary in sixty-eight per cent. In seven instances the contents of privy-vaults had overflowed upon the ground, and sewage was found upon the ground in thirty-five cases; swill was decaying on the ground or in privy-vaults in thirty-two cases; nine over-crowded neighborhoods were found; there were ten cases noted where the sickness had occurred in bedrooms in close proximity to privy-vaults. In many schoolhouses improperly trapped sinks were found. It was found also that in fifty per cent. of the cases the use of disinfectants during and after the illness had been wholly neglected.

Dr. Swarts then, by the aid of blackboard diagrams, explained several of the defects most frequently found in the plumbing of houses.

DR. H. G. MILLER reported the following cases:

MALINGERING.

A man who was a soldier in the late war, soliciting a pension, came to Dr. M's office, saying he was totally blind in one eye and that the vision was impaired in the other eye. Upon external examination the eyes seemed sensitive and irritated, without obvious cause. The ophthalmoscope revealed no abnormality in either eye, and the stereoscopic tests employed proved conclusively that vision was perfect in both eyes. The man was accompanied by his wife, and the case was the more noticeable from the apparent respectability of the parties. They both asserted that the man, in addition to his loss of vision, suffered from a foul, bloody, purulent discharge from one of his ears, which discharge, however, was not present at the time of their visit, as it disappeared occasionally. Upon examination, no perforation of the drum membrane, or any other lesion was found.

TUMORS OF THE ORBIT.

A woman, 50 years old, fell, striking on her forehead. Some months later a slight protrusion of the right eyeball, directly forward, was noticed, but there was no pain or impairment of vision. Two years later a swelling appeared just below the eyebrow at the inner angle of the orbit, accompanied by pain and defective sight, but as vision in the other eye was impaired, an operation was greatly dreaded. It was decided on finally, and an incision made parallel with the eyebrow. A tumor the size of a filbert was easily removed, but

the protrusion of the eyeball was not diminished. Further examination revealed another growth occupying the innermost part of the socket. The eyeball was then enucleated and the new growth excised, it being nearly double the size of the one first removed. The operation was followed by very severe cellulitis of the orbit. The tumors were not connected with the wall of the orbit or with the lachrymal gland, and it was hoped they would prove to be simple fibrous growths, and non-malignant. They had not as yet been examined microscopically.

IMPAIRMENT OF THE RETINA

at the macula lutea from looking at the sun with the naked eye. A commercial traveller, 25 years old, who rather prided himself on his strong eyes, attempted to observe the recent transit of Venus without a shaded glass. After looking at the sun nearly five minutes without special discomfort, he noticed his sight became blurred. This continued for a week before he sought treatment. When first examined his vision was about one-fifth. The macula presented a whitish appearance, as though coagulation had taken place there. He has gradually recovered his vision, which is now nine-tenths, and the whitish appearance at the macula has changed to a reddish one.

ELECTION OF A FELLOW.

Upon the recommendation of the Board of Censors, Dr. J. A. B. Tanquay, of Providence, was elected to Fellowship.

DR. S. S. KEENE read a paper upon

PNEUMONIA.

In regard to treatment, the writer denounced in severe terms the old system of venesection and other methods of depletion, claiming that science has demonstrated that an excess of fibrine in the blood is always present in this disease, and that *bleeding increases* the amount of fibrine by four hundred per cent; that the volume of blood is replaced in twenty-four hours from the lymphatics; that the crisis is not hastened; and that the danger is greatly increased of purulent infiltration from excess of white-blood corpuscles. The free use of antimony was also deprecated.

DR. H. BATCHELDER advocated a return to the old methods of treatment. He was surprised that any practitioner could denounce bleeding as dangerous. He himself had just been called to see a robust man in the first stage of pneumonia. He found him in a critical condition, lips purple, etc. He bled him freely, with a marked improvement in all respects. In his own practice, extending back forty-four years, he found, by his notes, he had treated in all 487 cases of acute pneumonia, in 376 of which he had performed venesection; of those bled only 2 died, while 7 of those not bled died. He believed also in the use of antimony, giving it until its specific effects were obtained. Its use requires caution, but rightly handled it is a sovereign remedy.

D. E. M. SNOW read a paper on the

EARLY HISTORY OF VACCINATION.

The first experiments of Dr. Jenner were described, the writer praising the prudence and wisdom shown by him in forseeing objections to his system, and preparing to meet them. The criticism and ridicule to which Jenner was subjected were alluded to, and an old engraving shown, in which was represented Jenner himself in the act of vaccinating a woman, while around him were men, women, and children, from whose heads, arms, and legs the heads of horses, and other members of horned creatures, had grown out—the result of inoculation with *bovine* virus. The first vaccinations performed in this country were by Dr. Benjamin Waterhouse, in Cambridge, Mass., in the year 1800, and probably in July. His own children were the first subjects, and in the month of August five of them were inoculated with smallpox virus, with no effect.

Dr. Artemus Stebbins, who lived with Dr. Waterhouse, made a business of vaccinating throughout the States of Massachusetts and Rhode Island, and to a certain extent in New Hampshire and Vermont. He used a large complicated apparatus for vaccinating, made of silver, at a cost of $40. This man Stebbins vaccinated in all 138,000 persons.

In the year 1810, Dr. Sylvanus Fanshers was employed to vaccinate the people of Providence, by a contract ratified in Town Meeting. He vaccinated here that year 4,305 persons, being paid about five cents for each one.

In 1816–17, Dr. John McKee vaccinated a total of 1,017 persons in Providence, among whom only one case of *bad arm* was reported. In 1856, the City Council of Providence adopted the plan of having free public vaccination performed at the office of the Superintendent of Health. Since then, Dr. Snow said he had vaccinated, in his capacity of Superintendent of Health, 28,365 persons, an average number annually of 1,091, the largest number in one year having been 2,798, in 1872. During this period he had issued 34,435 certificates of vaccination to school children.

DR. E. A. KEMP, of Lonsdale, reported a case of

MALIGNANT ULCERATIVE SORE THROAT,

first quoting from the work of Dr. J. Solis Cohen, on throat diseases, to show the rarity of such cases.

Dr. Kemp's patient, S. F., aged 22 years, married, of good family history, and a mill operative, came under treatment October 5, 1882, he having had a slightly sore throat for four weeks previous, but feeling able to work up to within three days of the date mentioned. On examination, both tonsils were found enlarged; and on the left one was a circumscribed phagedenic ulcer, about three-fourths inch in diameter; the mouth was opened with great difficulty; the face and eyelids were swollen, the eyes were glassy, and there was fever of a low type; there was dysphagia; the tongue was but little coated; the tonsils and gums were of a deep red color; the uvula and pharynx were œdematous; the ulcer presented a deep ash color; there was fetor of the breath.

The disease soon assumed a typhoid type. The voice was weak and muffled. On the eighth day of the disease the patient seemed better and was about the house. On the tenth day was worse; pulse 120; temperature 103½°; but still up and dressed. On the thirteenth and fourteenth days no particular change noted—keeps about the house, with pulse 140, and temperature 104½°. On the sixteenth and seventeenth days, pulse less rapid and patient seemed stronger. Eighteenth day, pulse 132; patient growing weak, but taking plenty of nourishment. Twentieth day, rather less œdema about the tonsils, small ulcerated spots appeared on the tongue; brandy, whiskey, sherry, and milk were given very freely. Ulcers appeared on the head and arms on the twenty-second day, and the patient died from exhaustion on the twenty-third day. A supporting treatment was maintained throughout. Locally, an attempt was made to pencil the surface of the ulcer with strong hydrochloric acid, but it caused so much pain it was discontinued. The mouth and throat were freely rinsed with liq. sodæ chlorinatæ.

DELIVERY IN THE ERECT POSITION.

DR. W. J. BURGE said he was recently called to a confinement case, and found the child had been born

nearly an hour. Delivery occurred suddenly while the mother was on her feet in a stooping posture, the child dropping to the floor. Those present simply wrapped it in a blanket and left it undisturbed. On examination the doctor found the child alive and the funis separated about five inches from the umbilicus. No hemorrhage had occurred and the child's condition was good.

DR. JOB KENYON mentioned a case where the woman was delivered while standing, and the cord was torn apart about five inches from the navel. No hemorrhage occurred and the child lived.

DR. GREELY said he knew of an instance of the cord being torn off *at* the *umbilicus* without injury to the child. Adjourned.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 15, 1883.

THE PRESIDENT, FORDYCE BARKER, M.D., LL.D., IN THE CHAIR.

THE subject of the paper of the evening was read by DR. F. R. STURGIS, and was entitled,

THE REPRESSION AND REGULATION OF PROSTITUTION.

The paper, the author said, was prepared at the special request of the President, it being one of the avowed objects of the Academy to promote the public health.

Three points were laid down for consideration:

First, the causes of prostitution.

Second, the necessity for regulation.

Third, the results obtained by legislative action.

Under the head of causes were enumerated, *first*, the man, as being the prime agent; this point was agreed upon by all writers on the subject in England, France, and America; *second*, the love of dress; *third*, the absence of proper home influences, which includes a *fourth* cause—the indiscriminate herding in tenement houses; *fifth*, the increase of luxury and civilization, thereby producing increased means for tempting women.

The arguments advanced in favor of regulating the evil were, *first*, the increase of syphilis. This disease was becoming more and more widely prevalent, particularly among the better classes. The number of young women, or those who came fresh upon the town, having contracted syphilis, were notably increased in our city hospitals. *Second*, the number of women in New York City, based on an estimate furnished by Sanger's statistics, was placed at 6,000, but this number probably represents only the known women, the clandestine class being found in the proportion of nearly six to one. Dr. Sturgis thought that Sanger's figures were too high. Depses' statistics probably came nearer the truth, being in the proportion of known women, 1 in every 601; clandestine, 1 in 104, of the population. Estimating the population at 1,000,000, this would give a total of over 11,000, while Sanger's statistics would make the number 42,600.

The effects of legislation in various countries went to show that, although it is impossible to suppress the evil, it is possible to keep it within bounds, and whenever women are found diseased, to insist on proper treatment. In this country, at least, one good point could be made, viz., that of insisting upon all persons found diseased by the police, or who voluntarily commit themselves at the charity hospital, to be retained there until cured, or until the surgeon considers them beyond the contagious period.

The paper was discussed by Hon. Judge Brady, Drs. Webber, R. W. Taylor, and Sturgis.

CORRESPONDENCE.

MR. SPENCER WELLS' OVARIOTOMY STATISTICS.

To the Editor of THE MEDICAL NEWS:

DEAR SIR: I have just received from Mr. T. Spencer Wells the subjoined communication, which I send to you at once in the hope that you will be able to give it an early insertion in THE MEDICAL NEWS as well as in the *American Journal of the Medical Sciences*. If your readers will refer to THE NEWS, of January 27th, they will find that the statistics of Mr. Wells' cases were furnished me by Mr. Thornton, and not compiled by me. They were originally intended for the new edition of my *Surgery*, but having reached me too late for insertion in that work, I obtained permission from Mr. Thornton to publish them in THE NEWS, where they appeared without one syllable or letter of alteration. In reading Mr. Wells' opening sentence, it might be inferred that I was the author of the statistics. It would have been well if the celebrated ovariotomist had said that the *statement* to which he therein refers had been based upon Mr. Thornton's statistics, as that would have rendered the matter perfectly clear as far as it concerns me. Mr. Thornton's statistics dealt only in generalities, and not in any details respecting the gradually diminishing mortality of Mr. Wells' successive series of one hundred cases. In doing this the distinguished ovariotomist had, I am sure, no intention of misrepresenting his friend Mr. Wells, for whom he has always cherished the warmest regard and highest esteem. It may gratify Mr. Wells, as it certainly does me, to know that the new edition of my *Surgery* contains an accurate account of his statistics derived from his own recent work on ovariotomy.

I have the honor to be

Your obedient servant,

S. D. GROSS.

PHILADELPHIA, March 17, 1883.

3 UPPER GROSVENOR STREET, LONDON,
February 27, 1883.

MY DEAR PROF. GROSS: You have published in the Philadelphia MEDICAL NEWS a statement comparing the results of my operations of ovariotomy in 1088 cases with those of three other operators in 381, 328, and 226 cases respectively, making a total of 935 cases. The mortality of my cases is given correctly at 22.15 per cent.; and that of the other operators as 10.76, 10.67, and 11.94 per cent. On this plain statement, as you have published it, any one would conclude that I am a less successful operator than my juniors. Indeed, the author of a very eulogistic review of my last book in the *American Journal of Medical Sciences*, of January, 1883, misled by a false statement in the *American Journal of Obstetrics* (vol. xv. page 547), that I "had gone on for twenty years operating on hundreds of cases with a mortality of 25 per cent.," takes the trouble to give what he believes to be a true explanation of the "high range of mortality in his [my] ovariotomies." He says that I had labored for an "ideal success;" but "his [my] own practice fell short of this ideal." If it were true that after twenty years' operating, I had gone on operating with a mortality of 25 per cent., while others did not exceed 10 or 12, some such explanations as those proffered by my able and kindly reviewer might serve as my excuse. But it is not true. When I had been operating for twenty years, I had reduced my mortality to 11.62 per cent. The results of successive series of 100 cases had been made known, from 34 in the first, and 28 in the second, to 17 in the ninth, and 11 in the tenth series of 100 cases. My cases of 1879, 1880, and 1881 had been published, with results of 11.62, 9.57,

and 10.7 per cent.; and in the preface to my book, published in May, 1882, I afford proof that, "notwithstanding the fact of my being often called upon to treat patients rejected by other surgeons as unfavorable cases, the progressive diminution of the mortality still continues." I added, "It is still more gratifying to be able to add that this increasing success is not confined to myself nor to British surgeons, but is also established in Germany, France, and Italy." There really can be no excuse for this attempt to discredit me with a high mortality after twenty years' experience, as in my book (pp. 214, 215) I had shown very plainly how in successive periods of five years the mortality progressively diminished, and that in the

First five years,	about 1 in 3	died.
Second and third five years,	" 1 in 4	"
Fourth five years,	" 1 in 5	"
Last two years,	" 1 in 10	"

Or, putting it in another form, that in the

First five years,	70 per cent.	recovered.
Second five years,	74 "	"
Third five years,	73 "	"
Fourth five years,	80 "	"
Two last years,	90 "	"

I trust, my dear Professor, that you will accept my desire to stand well with my American brethren as a sufficient excuse for this long letter. And with sincere respect, I am, etc.,

T. Spencer Wells.

NEWS ITEMS.

CANADA.

(*From our Special Correspondent.*)

Doctors in Canadian Legislatures.—In the Dominion and Provincial Houses at present in session, there are sixty members of the profession—a representation of about two per cent. Half of these are in the Dominion Parliament, seven in the Senate, and twenty-three in the House of Commons. Eight are graduates of English Universities, twelve of American, and the remainder of Canadian. Of the American colleges, Harvard is represented by six, University of Pennsylvania by three, University of New York by two, and Rush by one. Nearly all of these are members from constituencies of the maritime provinces.

Anatomy Act.—The government of the Province of Quebec has brought in important amendments which may do away with the practice of body-snatching, so common here. Two inspectors are to be appointed, with sub-inspectors in each judicial district, who are to see that all unclaimed bodies in institutions receiving government aid are handed over to the schools. The institutions are to notify the inspectors within twenty-four hours of the death of friendless individuals. Claimants must show relationship within the third degree. Schools and colleges are to pay ten dollars apiece for the bodies, the fee to go to the inspectors, and to cover cost of removal, etc.

Professor Croft.—The death is announced of this well-known Canadian chemist, who for thirty-five years occupied the chair of Chemistry in University College, Toronto. During this long period he was the leading expert in all cases of poisoning. He was superannuated two years ago, and has since been living in Texas, where he died on the 28th ult., aged 64.

LONDON.

(*From our Special Correspondent.*)

The Students' Medical Associations are carried on in connection with the individual medical schools. Each school of any size and standing has its own medical society, managed by the students. In some, the teachers take no part whatever; in others, they act as presidents, or even share more largely in the management. The societies are primarily for the purpose of holding meetings once a week or alternate weeks, for the discussion of scientific topics, and exhibition of objects of interest; and in connection with some of them are a reading-room, library, microscopes, osteological and other preparations. The subscription is small, and nearly all students join. Perhaps the most famous of all is the Abernethian Society, of St. Bartholomew's Hospital, in which the staff of the hospital take a great interest. An account of a recent meeting of the Middlesex Hospital Medical Society, of which Dr. Douglas Powell is president, may interest or show what a good work such meetings do. Dr. Powell was unavoidably absent from this meeting, and one of the senior students took the chair. The proceedings throughout were most orderly. From the minutes of the last meeting, it appeared that then a paper on chorea, with special reference to its pathology—the writer, a student, contending that the disease was a rheumatic affection of the neuroglia.

Then Mr. Sutton, one of the demonstrators of anatomy, was called upon to show some specimens. These were—1. A large encephalocele projecting through the occipital bone, and containing the cerebellum; it was covered with healthy skin; there was no hydrocephalus. 2. A single kidney in a fœtus in which there was no trace of the left organ, or of its artery, vein, or duct; but the suprarenal capsule and testicle of the same side were entire. 3. A specimen of congenital obliteration of the middle of the third part of the duodenum, with great dilatation of the stomach above—and this, although the child had only lived a few moments. 4. An ovary and Fallopian tube which had been removed from the inguinal canal of a young woman who had no vagina or uterus. Between the ovary and duct were two tiny cysts of the organ of Rosenmüller. 5. A cancerous tongue in which one lingual nerve was traced passing into a mass of cancerous infiltration; the patient suffered severe pain during life. 6. Nerves from two stumps showing bulbous enlargement of their ends. 7. A gall-stone surrounded by a thick false membrane, and lodged in a small depression in the upper surface of the liver. 8. A specimen of anteflexion of the uterus of a water deer. 9. And a specimen of anteflexion of the uterus of a baboon in which there was great atrophy of the concavity of the bend; this specimen would have greatly interested Dr. Graily Hewitt and his disciples. 10. A ruptured vagina from a hyena: this was produced during parturition, and three young hyenas were found in the peritoneal cavity. 11. Necrosis of lower jaw from monkey. 12. White patch on heart of a bird. 13. A remarkable parasitic disease in an African carnivorous animal. These specimens were not only described and inspected, but with regard to most of them Mr. Sutton added anatomical and pathological remarks of interest and oftentimes novelty. I think your readers will agree with me that such an evening's work is not unworthy of any medical society. Afterwards a few of the students spoke, referring to similar cases, or asking apposite questions, and one of the assistant surgeons of the hospital, who happened to be present, made remarks on several of the specimens. Another member of the Society exhibited several microscopical sections of amphioscus, human retina, etc., and then the meeting was closed with refreshments in the form of tea and coffee. It is impossible to doubt that such meetings must exert a very powerful influence for good upon the students, educating them, and fitting them in many ways for their future position in society.

The London Medical Union.—A scheme of quite a different kind has just been started in London. This is a club for medical students of all the schools, which in addition to supplying the ordinary accommodation of a club, holds meetings for scientific discussion; gives musical entertainments, and aims at collecting a scientific and general library. The great difficulty it has to overcome is, that already the better class of students have their time too fully occupied to be able to frequent a club; and hence it is in danger of becoming the resort of the less industrious students. Most teachers have from time to time felt the want of residential colleges for our medical students. At present, with very trifling exceptions, the students live in more or less discomfort in lodging houses; some of the more favored ones finding a home with medical men connected with medical schools. This exposes the men—many of them very young—to great temptations; and is, do doubt, one important cause of the failure of many to steer straight through the rocks and shallows of their student days. At King's College, University College, and St. Bartholomew's Hospital, there is a small residential college in connection with the schools. But the London Hospital, which is situated far in the East of London, is about to make the most important experiment in this direction that has yet been made. Should it succeed, it will be necessary for the other schools to provide similar accommodation, in self-defence; and this would make it difficult, if not impossible for one or two of the smallest schools to hold their own at all.

The Tubercle Bacillus, and its Relation with Phthisis and Tuberculosis.—Some months ago the "Scientific Research Association" requested Mr. Watson Cheyne to investigate this subject, and his report has this week been presented to the council of the Association, and will shortly be published; and I must postpone any further allusion to it until the full text of it is at my disposal. The whole question is of course exciting much interest here, and a very good discussion on it has recently been held at the Medical Society of London.

The Bellevue Hospital Medical College.—The twenty-second annual commencement of the Bellevue Hospital Medical College was held in Chickering Hall, New York, on the 14th inst., and the degree of M.D. was conferred on one hundred and sixty-seven candidates by Dr. Isaac Taylor, the President of the Faculty. The valedictory address was delivered by Dr. S. D. Gross, of Philadelphia. He advised the young graduate that the Code of Ethics of the American Medical Association should be his guide; it was "the palladium of his rights, and the ark of his safety; he who dishonored it, dishonored his profession."

The Fruits of the New Code.—A Louisville correspondent of *The Louisville Medical News*, writes to that journal for the yea and nay vote on the New Code at the late meeting of the New York State Medical Society. He says "It is often necessary to refer our friends and patients going eastward to physicians, and it is important to know those members of the New York State Society who have voluntarily severed their connection with the medical profession of the country, so that we may advise accordingly."

Luzerne County (Pennsylvania) Medical Society.—At a stated meeting of this Society held at Wilkesbarre on the 14th inst., a resolution was unanimously adopted instructing the delegates to the State Medical Society to vote against electing any delegates to the New York State Medical Society Meeting, and to oppose any action tending to recognize that Society in any way whatever.

Dr. William S. Forbes was tried last week on two indictments. The first was for a violation of sepulture, and the second was for conspiring with certain parties to rob the graves of Lebanon Cemetery. In each case the jury rendered a verdict of "not guilty."

Cholera in Calcutta.—During the fourth quarter of the past year Calcutta suffered from an unusual rise in its mortality from cholera. The deaths from this disease in October numbered 91, in November 232, and in December 411, making a total of 734 for the quarter, or 373 in excess of the mean number for the corresponding quarters of the preceding ten years. The first indication of unusual cholera prevalence, was the occurrence towards the end of October in some villages of the suburban section, Chitpore, of a very serious outbreak among the coolies employed among certain jute-presses. Close upon 200 of these were attacked in a few days, and the great majority of them died very rapidly. At this time cholera did not prevail with any severity in either town or suburbs, but subsequently the disease became very general throughout both areas. The incidence of the disease in the town was sporadic. A group of cases seldom occurred in one house or locality, but when this did occur, very unsanitary conditions were found in the vicinity. The disease was of a virulent type, the proportion of deaths to cases being remarkably high. The disease did not present any tendency to ascent until after a heavy rainfall, 6.78 inches, which took place on October 15, but with the cessation of the rains and change in the monsoon it made very decided progress, especially in December. About the middle of that month, however, an abatement began; but the mortality rate at the latest dates February 1, continues higher than the average.

What is Said of the Recent Action on the New Code.—There has been no change of sentiment and no recantation of error on the part of those whom these so-called enlightened reformers, masquerading under the disguise of humanitarians, are so anxious to meet by the bedside of wealthy victims of disease.—*New England Medical Monthly*, March 15, 1883.

Memphis Hospital Medical College.—The annual commencement of this institution was held on the 2d inst., and the degree of M.D. was conferred on thirty-two candidates. Prof. B. G. Henning delivered the charge to the graduating class.

Medical College of Ohio.—The Sixty-fourth Annual Commencement of the Medical College of Ohio was held on March 8th, the degree of Doctor of Medicine being conferred on one hundred and two graduates. The valedictory address was delivered by Dr. Thad. A. Reamy.

Vaccination in Ghent, Belgium.—Smallpox has appeared in Ghent, according to late advices, and a notice has been issued by the city authorities inviting the people to get vaccinated free of cost, and offering a fee of twenty cents to those bringing proof that the operation has been successful.

American Cholera?—Reports from Mr. Langner, Consular Agent of the United States at Tehuantepec, Mexico, describe the occurrence of a terrible epidemic of choleraic disease, which has prevailed in the States of Tehuantepec, Oaxaca, and Tabasco. It began in the city of Tehuantepec on December 13, increased rapidly during the two weeks which followed, until,

about its acme, one hundred persons died each day. In January the epidemic began to abate, and by the middle of the month had almost, but not entirely, disappeared.

The deaths in the city during the four weeks of the epidemic amounted to fourteen hundred, or nearly to one in ten of the population, the city being said to have fifteen thousand inhabitants. The surrounding villages suffered in like manner from the visitation.

The reports divide the progress of the disease into three periods. During the first the tongue is coated, pulse slightly increased, evacuations fetid, and speedily becoming loose. This primary diarrhœa may continue for two days. During the second period, the evacuations become watery and transparent, cramps are felt in the stomach, with vomiting at first of bilious matter, the ejecta afterwards becoming colorless and transparent. In the third stage, the cramps and other spasms which had already appeared at the end of the second period, became more frequent and vehement; cold perspirations cover the whole body, the extremities become colder, the eyes sunken and surrounded with a bluish areola, the voice reduced to a whisper, the thirst insatiable, pulse weak, complexion cadaverous—the extremities sometimes acquiring a bluish color.

The disease in most cases ran a course of two to three days, but some of the attacks were of extraordinary vehemence, hurrying to the grave in from four to eight hours those who before had enjoyed perfect health. In such cases all the dangerous symptoms were present at the same time.

The remedies used were clysters of linseed infusion and opium, anti-choleraic tincture, dieting, and mustard cataplasms to the epigastrium. An infusion of orange leaves was also used.

Here we have Asiatic cholera in everything but name and derivation, which are very secondary matters, decimating the people of a large section of North America. In a few years, when railroad communication branches southward, such an epidemic will assume a grave aspect to the people of the United States. Owing to the perfection of the health laws of Europe the presence of cholera at Camaran, Jeddah, Mecca, Suez, or elsewhere, on its way from India, is known to us within a few hours after its development and detection, and we become protected by the barriers of enlightened and effective quarantines, which the European authorities interpose. But from cholera on this continent we have no protection. In health legislation we are far behind the age; and the recent action of Congress in failing to respond to the appeal of the profession gives, what seems a serious check, to our progress. But all things come round to those who will but wait, —*and work*. The history of health legislation in all countries shows that, while its course has not run smoothly, the checks which it has encountered have been but temporary in character. So it will prove with us.

TYPHOID FEVER AT LIEGE, BELGIUM.—The State Department has received a report from Mr. Nicholas Fish, our Minister at Brussels, giving an account of a recent epidemic of typhoid fever at Liege. The disease began early in December last, its first victim dying on the 17th of that month. The report extends to February 11 inclusive, during which period 341 persons suffering from the disease were admitted into the civil hospitals. How many were treated in the military hospitals and at their own homes is not stated, but as 182 deaths from the fever were reported during this period, of which only 24 occurred in the civil hospitals, while 144 took place in private houses, and 14 in the military hospitals, we may infer that the total number of cases must have amounted to about 2500.

The greatest mortality appears to have been among males of from 20 to 25 years of age, and among females between the ages of 15 and 20, amounting to 27 of each. Of the 182 deaths, 88, or 48.3 per cent., were among persons between 15 and 25 years of age, while but 21, or 11.5 per cent., occurred among those over 30 years of age. The deaths among females were 101, or 55.5 per cent., and among males 81, or 44.5 per cent. The census of 1880 gave Liege a population of 123,131.

The epidemic was at first light, there having been but 8 deaths to the end of December, and but 1 from January 1 to 10; but during the twenty days from January 11 to 31, there were 110 deaths. From February 1 to 11 there were 73 deaths, and the greatest mortality, 15 deaths, occurred on February 5. From February 7 there was a decrease in the number, the deaths being 5, 4, 2, 3, 1, from the 7th to the 11th respectively.

Mr. Fish calls attention to the fact that Liege is situated in a district which suffered greatly by the floods last summer and autumn; that the winter during which the outbreak took place was exceptionally mild, greatly resembling the ordinary spring weather on the banks of the Ohio, and that the epidemic was preceded by an unusual continuance of rainy weather.

THE VALUE OF VACCINATION.—In the Annual Report of the Medical Officer to the President of the Local Government Board, for the year 1881, the operation and value of the English vaccination laws are demonstrated by an examination of the smallpox deaths occurring in the hospitals and houses of London in 1881, undertaken at the request of Dr. Buchanan, by Dr. H. Stevens. Of the 2379 deaths from smallpox which occurred during the year, children under fifteen years of age numbered 1125, or not quite half the total number; children under ten numbered 953; under five 667. Formerly, in the twenty years before 1871, when public vaccination was gratuitously provided, but when compulsion was little more than nominal, more than half the deaths from smallpox that occurred in London were of children under their fifth year. In the ten years, 1851–'60, these children contributed 59.5 per cent. to the all-age smallpox mortality of the metropolis; and in 1861–'70 they contributed 54.3 per cent.; while in the year 1881 they formed only 27.8 per cent. of the total smallpox mortality. These figures show that it is especially to the advantage of children that vaccination has been made compulsory.

In comparing the mortality of the vaccinated with that of the unvaccinated, the cases of children under ten years are specially studied. In 1881 the population of London, under ten years, was in round numbers divided into 55,000 unvaccinated and 861,000 vaccinated. Among the 55,000 who had not been vaccinated, there occurred 782 deaths; while among the 861,000 who had undergone vaccination, the deaths numbered 125. Upon equal numbers of the two clases, therefore, the mortality from smallpox among the unvaccinated was about a hundredfold the mortality of smallpox among the vaccinated. If the London children under ten years of age who were unvaccinated had had the protection which the current vaccination gives, not 782 of them, but at the outside *nine*, would have died of smallpox during the year; while if the 861,000 vaccinated children had died at the rate of the 55,000 unvaccinated, not 125, but 12,224 deaths would have taken place among them. This saving of life was essentially the effect of vaccination. But the average current vaccination of London is of various sorts; and Dr. Steven's inquiries have touched upon the relative value of public and private vaccinations. The 125 children under ten who died of smallpox, after an alleged vaccination, have to be reduced to 117, by deducting those who on his personal inquiry were

found not to have been vaccinated at all, or to have been "unsuccessfully" vaccinated; and this number 117 divides itself into 82 vaccinated by private practitioners, and 35 by public vaccinators; while the number of vaccinated children under ten is made up of about equal numbers of each class (53 per cent. at the public expense, and 47 per cent. by private practitioners). When the 35 deaths which are reported to have occurred among those publicly vaccinated are examined, 12 of them are found to have been vaccinated only after their exposure to the smallpox infection, when it was too late to prevent them from catching the disease, and too late to modify its virulence. The remaining 23 cases are made up of two cases that could not be traced, and, in about equal numbers of cases where the child was ill of some independent disease when it became affected with what was registered as smallpox (in a few cases it is doubtful whether smallpox was present at all), and of cases where the vaccination marks, although the work of the public vaccinators, were scanty or imperfect. In only one case had vaccination been performed in the manner contemplated by the instructions of the board. This case finds its parallel in those occasional cases where smallpox itself attacks a person, often severely, and yet leaves him liable to death from a second attack of the same disease after a few years' interval.

During the year 12 deaths were registered in London as from "cowpox" and disease occurring after vaccination. Inquiry into the facts of the several deaths showed that the cause of death, with hardly an exception, was erysipelas, derived from one source or another, and seldom even dating from the vaccination. Dr. Buchanan concludes: "Supposing all the 12 deaths had been justly attributed to vaccination, and had been unavoidable results of vaccination, then 12 lives lost by vaccination have paid for the gain of 12,000 children's lives that would, but for vaccination, have been sacrificed to smallpox, not to mention any gain of security after childhood, afforded by vaccination in infancy." The price has not, in truth, been so high as this; but the complete abolition of every such drawback to vaccination is the aim of every one who appreciates the value of the operation.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending March 10, 1883, indicate that measles and bronchitis have increased, and that erysipelas, intermittent fever, and consumption have decreased in area of prevalence. The reports also indicate that there was a general decrease in sickness.

Including reports by regular observers, and by others, diphtheria was reported present during the week ending March 10, and since, at fourteen places, scarlet fever at nineteen places, and measles at seventeen places. Two cases of smallpox at Detroit March 14.

OBITUARY RECORD.—The weekly *Bulletin de Statistique Municipale*, of Paris, No. 9, March 3, 1883, announced the death of M. Bertillon, Chief of the Bureau of Sanitary Statistics. In 1858 M. Bertillon first raised the important question of infant mortality in Paris, by showing that the department of the Seine and the thirteen departments which surround it furnished 35,000 deaths among children under one year of age, for 173,000 births; while in the rest of France, for an equal number of births, the number of deaths was but 26,000. His labors furnished the most satisfactory arguments in favor of the passage of the law of 1874 for the protection of infant life. His latest work was the reorganization of the service of the City Bureau of Statistics, at the head of which he was placed in 1880. He was sixty-one years of age.

—— On February 23d, in the ninety-third year of his age, PROFESSOR JULES GERMAIN CLOQUET.

Prof. Cloquet was born in Paris in 1790, and obtained his medical education there and at Rouen, his thesis for the *doctorate* being on abdominal hernia. He was elected to the Academy in 1821. Cloquet was a brilliant operator and the author of a large number of valuable papers on surgery and natural history.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 12 TO MARCH 19, 1883.

MURRAY, ROBERT, *Colonel and Assistant Surgeon-General.*—Detailed as member of Army Retiring Board to convene at the call of the president thereof, at Governor's Island, New York Harbor, for the examination of such officers as may be ordered before it.—*Par. 2, S. O. 62, A. G. O., March* 16, 1883.

SUMMERS, JOHN E., *Lieutenant-Colonel and Surgeon.*—Detailed as member of Army Retiring Board to convene at the call of the president thereof, at Omaha, Nebraska, for the examination of such officers as may be ordered before it.—*Par. 9, S. O. 62, A. G. O., March* 16, 1883.

BILL, JOSEPH H., *Major and Surgeon.*—Detailed as member of Army Retiring Board to convene at the call of the president thereof, at Omaha, Nebraska, for the examination of such officers as may be ordered before it.—*Par. 9, S. O. 62, A. G. O., March* 16, 1883.

BROWN, HARVEY E., *Major and Surgeon.*—Temporarily assigned to duty at Mount Vernon Barracks, Alabama, during the absence on leave of Captain T. A. Cuningham.—*Par. 2, S. O. 17, Department of the South, March* 6, 1883.

IRWIN, B. J. D., *Major and Surgeon.*—Detailed as member of General Court Martial to meet at Whipple Barracks, Prescott, Arizona Territory, April 23, 1883, for trial of Captain J. P. Walker, 3d Calvary.—*Par. 1, S. O. 62, A. G. O., March* 6, 1883.

JANEWAY, JOHN H., *Major and Surgeon.*—Detailed as member of Army Retiring Board to convene at Governor's Island, New York Harbor, for the examination of such officers as may be ordered before it.—*Par. 2, S. O. 62, A. G. O., March* 16, 1883.

WILLIAMS, J. W., *Major and Surgeon.*—Upon being relieved from duty at Fort Coeur d'Aléne, Idaho, will proceed to Fort Walla Walla, Washington Territory, and report for duty as medical officer of that post.—*Par. 5, S. O. 24, Department of the Columbia, March* 1, 1883.

CUNINGHAM, T. A., *Captain and Surgeon.*—Granted leave of absence for twenty days, to take effect from the 21st instant.—*Par. 1, S. O. 17, Department of the South, March* 6, 1883.

GIRARD, JOSEPH B., *Captain and Assistant Surgeon.*—Detailed as member of General Court Martial to meet at Whipple Barracks, Prescott, Arizona Territory, April 23, 1883, for trial of Captain J. P. Walker, 3d Calvary.—*Par. 1, S. O. 62, A. G. O., March* 16, 1883.

HEIZMANN, CHARLES L., *Captain and Surgeon.*—To be relieved from duty in the Department of the South, and assigned to duty at Columbus Barracks, Ohio.—*Par. 8, S. O. 58, A. G. O., March* 12, 1883.

TAYLOR, B. D., *Captain and Assistant Surgeon.*—To be relieved from duty at Fort Ringgold, Texas, and will, so soon as able, report to the commanding officer Fort Clark, Texas, for duty.—*Par. 6, S. O. 25, Department of Texas, March* 9, 1883.

WINNE, CHARLES K., *Captain and Assistant Surgeon.*—Granted leave of absence for three months from March 31, 1883, and will be relieved from duty in the Department of the East, and upon the expiration of his leave of absence will report in person to the commanding general Department of California, for assignment to duty.—*S. O. 61, A. G. O., March* 15, 1883.

WOOD, MARSHALL, *Captain and Surgeon.*—Is assigned to duty at Fort Coeur d'Aléne, Idaho.—*Par. 5, S. O. 24, Department of the Columbia, March* 1, 1883.

BRECHEMIN, LOUIS, *First Lieutenant and Assistant Surgeon.*—To proceed to Fort Brady, Michigan, and report to the commanding officer for duty at that post.—*Par. 1, S. O. 41, Department of the South, March* 14, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

DIABETES MELLITUS.

A Clinical Lecture, delivered at the Philadelphia Hospital, December 9, 1882.

BY JAMES TYSON, M.D.,

PROFESSOR OF GENERAL PATHOLOGY AND MORBID ANATOMY IN THE UNIVERSITY OF PENNSYLVANIA, AND ONE OF THE PHYSICIANS TO THE HOSPITAL, ETC.

(Reported by DAN W. NEAD, M.D.)

GENTLEMEN: The patient whom I show you is 70 years of age, a tailor, who was admitted to the Hospital August 31, 1882. According to his own account, he always had fair health until three years ago, when he noticed that he was passing more urine than usual, and was continually thirsty. At the same time he was annoyed by a dryness of his throat and mouth.

It was with these symptoms that he was admitted to the hospital, and they at once suggested an examination of his urine, which was found to contain sugar. Our first note is dated September 7th, when he passed ninety-six ounces with a specific gravity of 1032, and the next day he passed one hundred and twelve ounces, having the same specific gravity. The first quantitative analysis was made on the 10th, when the urine was found to contain twenty-one grains to the fluidounce. I apply the tests in your presence, and you notice both the Fehling's copper test and Bötger's bismuth test respond promptly, the former precipitating the red cupric sub-oxide, and the latter black metallic bismuth.

You will find in the books, in addition to those named, quite a long category of symptoms, which are at times found associated with saccharine diabetes, but those we note in our patient, viz., dryness of the mucous membranes, unusual thirst, and the passing of an increased quantity of urine, of high specific gravity, and containing sugar, are, after all, those essential to a diagnosis. A frequent mode of termination of the disease is by tubercular phthisis, when, of course, are superadded the symptoms incidental to it. Among others, is an annoying itching about the *meatus urinarius*, caused by the constant passage of the sugar-charged urine over it, and in females this sometimes extends to surrounding parts, producing a distressing *pruritus vulvæ*. Emaciation, great muscular weakness, and the loss of sexual inclination are symptoms incident to the malassimilation of ingested food, which, though taken sometimes in more than sufficient quantity, fails to serve its purpose.

Without delaying further, therefore, to discuss the less essential symptoms of the disease so evidently present, let us ask ourselves the question, what is diabetes mellitus? It is scarcely necessary for me to say to you that it is not a disease of the urinary organs. Its study has naturally fallen into the hands of those interested in these diseases, because it requires for its recognition a study of the urine. But the kidneys are simply the organs which eliminate the sugar from the blood, which is there in undue quantity. Glycosuria, or saccharine urine, implies glycæmia, or saccharine blood. If there is no sugar in the blood, there can be none in the urine.

A certain relation of the nervous system to glycosuria has been known to exist since Bernard's discovery that puncture of the floor of the fourth ventricle produced it. Since then it has been found to succeed upon section of the medulla oblongata, the optic thalami, and great crura cerebri; by destructive lesions of the pons, and middle and posterior crura cerebelli; section of the spinal cord above the second dorsal vertebra; by section of filaments of the sympathetic nerve ascending from the first thoracic ganglion to accompany the vertebral artery; by removal or injury of the superior cervical ganglion; and sometimes, but not always, after section of the sympathetic in the thorax; and even after section of the nerve trunks of the limbs, as the sciatic.

With such glycosuria is invariably associated an active hyperæmia of the liver. It must be remembered, also, that an important function of the liver is the formation of the so-called glycogen or animal starch from the starchy and saccharine articles of food, and to a slight extent from albuminous food. Thus produced, it is stored in the liver, but reconverted into sugar and passed into the blood in such quantities as are demanded by the organism, for oxidation. Remembering this function of the liver, there are two ways in which an excess of sugar may get into the blood. Either the grape sugar, formed by the digestion of sugar and starches, may pass too rapidly through the hyperæmic liver to permit its conversion into glycogen, or having undergone this conversion, it is too rapidy reconverted into grape sugar to be oxidized. The blood soon acquires an excess of glucose, and the latter then appears in the urine. It has been ascertained by experiment that when the amount of glucose in the blood exceeds one-quarter of one per cent. it makes its appearance in the urine.

But in whichever of these ways the result is produced, the hyperæmia of the liver is always present. Hence it follows that whatever will produce such hyperæmia may produce diabetes, whether it operate through the nerve centres or not. Two cases of diabetes have come under my notice in which the symptoms were preceded by biliary colic and passage of gall-stones. The one has disappeared under treatment, the other remains uncured. Artificial irritation of the liver by needles and galvanic currents has also produced glycosuria. While injuries and diseases of the nervous system are often accompanied by glycosuria, there are many cases in which it is impossible to discover any relation between the two conditions, and not all cases of diabetes, nor even a majority, dare be considered diseases of the nervous system. It is not unlikely that sometimes the hyperæmia of the liver is a reflex one, being caused by irritative influences operating through the pneumogastric nerve (which is the sensory, and not the motor, nerve of the sugar-forming process) upon the diabetic centre, and thence through the vaso-motor nerves in the spinal cord and sympathetic upon the bloodvessels of the liver. Among these reflex relations must be placed derangements of digestion, which, acting upon the end filaments of the pneumogastric, produce the requisite irritation and its reflex results. It must be admitted, however, that there are still many difficulties in the way of explaining the phenomena of diabetes mellitus. Thus, admitting that a certain number of cases, which cannot be due to central nervous lesions or disease, are the result of reflex irritation, how are we to account for the continuation of the symptoms after the irritation has apparently disappeared? Can it be that the liver, once thrown into

this hyperæmic state, by reason of a sort of inertia, cannot return to its natural condition while such articles of food are given as stimulate its glycogenic function?

In autopsies, alterations in the liver, both of a gross and microscopic character, are sufficiently frequent to make it reasonable that temporary or permanent changes in this organ are at the bottom of a large number of cases of diabetes. These changes are chiefly of size, color, and consistence. The liver is darker and harder, and, while sometimes it is only slightly enlarged, at others it is three times as large as in health. For the more minute changes I must refer you to the books. But it cannot be denied that these changes may be the result of hyperæmia also. Diabetes has been associated, not infrequently, with pancreatic disease.

It is not impossible also that a transient glycosuria—it should scarcely be called saccharine diabetes—may result from an over-ingestion of sugar-forming substances. Any one may produce on himself a glycosuria by the too free consumption of saccharine and amylaceous foods.

Whatever may be the difficulties in the way of explaining the phenomena of diabetes from the standpoint of digestive derangement, that some such relation exists is shown by the result of *treatment*. For by far the most frequently successful plan of treatment is that which excludes saccharine and farinaceous articles from the diet. It occasionally happens that this fails to relieve the symptoms, and when this is the case we may infer that some serious lesion of the nervous system is at the bottom, or more likely, perhaps, that the liver has become secondarily so much altered that it cannot resume its functions, and that now even albuminous foods are being converted into sugar. Of the selected food, that which gives the most satisfactory results is a diet of *pure skimmed milk*, or buttermilk. Our patient has been carefully tested on this system of diet. On referring to the notes, I discover that on October 30th he was passing fifty-six ounces of urine, of a specific gravity of 1029, and containing eighteen grains of sugar per fluidounce. On the day before this he passed seventy-six ounces, specific gravity 1038, and containing twenty-three grains of sugar to the fluidounce. On the thirtieth day he was placed entirely upon a milk diet, and we had an immediate diminution in the amount of sugar passed. On November 1st, there were only ten grains of sugar per ounce; the amount of urine passed in twenty-four hours still remained at fifty-six ounces. Replacing him upon a mixed diet, immediately the quantity of urine and the proportion of sugar rose, to be again reduced on restoring the skim-milk diet.

It is found sometimes that a patient is not able to bear a milk diet, although this occurs less frequently than might be supposed. Pure skimmed milk is to be preferred, chiefly because of its easier assimilation. Some observers, of whom Dr. Donkin is the chief exponent, claim that the skimmed milk has a special curative action, but I cannot see any reason for this. All that is removed from it by skimming is the fat, and fat is not converted into sugar in the liver. It is most interesting to observe that under the use of large quantities of milk how much less urine is passed than fluid ingested. The body weight can easily be maintained on a milk diet, although it is impossible to lay down a rule as to absolute quantity required. I have known the weight to be maintained by two quarts per day, and I have known five and seven a day to be necessary. The milk is best administered at stated intervals and in fixed quantities. I always begin with eight ounces (an ordinary tumblerful) every two hours, increasing as required.

If a milk diet cannot be borne, a restricted diet can be obtained, which is better than a mixed diet. A purely albuminous diet is almost unendurable for any length of time, but there are certain vegetables which contain but a small amount of sugar-producing substance which may be added to meat. Such are the "green" vegetables, including spinach, cabbage, tops of celery, green peas, beans, etc., as well as the acid fruits, and, by a diet such as this, the most surprising results may be obtained. It appears that the vegetable sugars, as those found in berries, are more easily assimilated than cane sugar. Even where a skim-milk diet is well borne, my practice, after the sugar has disappeared, is to gradually add other articles, in the shape of oysters, game, and green vegetables, watching the urine for any return of the sugar; and it is always important to keep a case under observation for some time after sugar has disappeared from the urine.

An article of food which is much missed by some is *bread*, and it is scarcely necessary to say that it is one of the most objectionable, because of the large amount of starch it contains. And I regret to say that I have not found gluten bread a satisfactory substitute. A recent experience will illustrate. I have now under my care, a lady who had been for nine months under treatment for diabetes before I saw her, but in whose case the pure skimmed milk had never been tried. She had finally, in despair of recovery, been allowed to take anything she wanted, and when I first saw her, was drinking a quart of champagne daily to quench her thirst. It is needless to say this was discontinued, and she was put upon a pure skim-milk diet, and an unlimited amount of Apollinaris water. In ten days the sugar had disappeared, and shortly thereafter I permitted the gradual addition of other articles of diet, including green vegetables. All went well until she asked to be allowed to take some gluten bread, which I permitted. In three days I examined the urine, and sugar was again present. The gluten bread was discontinued, and in three days the sugar had disappeared. The resumption of gluten bread was followed by the return of sugar, and its withdrawal by the disappearance of the sugar. Such an experiment is, I think, conclusive. Of course, it is not claimed by the makers of gluten flour, that it is completely free from starch, but as it is already a rather uninviting food in its present state, the inference is, that when it is entirely freed of starch, the bread made from it will be scarcely tolerable. At the same time it must be admitted that the gluten bread contains less starch than the ordinary wheaten bread, and there may be cases in which the starch of the former is assimilated, when the quantity in the latter could not be. The same may be said of the so-called "bran bread," made of unbolted flour. With other substitutes for wheaten flour, as the almond flour of Pavy, bran flour, inulin, etc., I have had no experience.

Are drugs of any use in the treatment of diabetes? I believe they are, although if compelled to rely upon drugs or diet alone, I should prefer diet. The most efficient remedy is probably *codeia*, although I am almost afraid to say this, for a few months ago I should have given the palm to *ergot*, and until recently I have always used it first. The use of ergot is based upon scientific principles, since it is well determined that it exerts a contractile influence upon the walls of bloodvessels, thus counteracting hyperæmia. I have frequently used it, and have no doubt whatever of its efficiency. The best preparation is the fluid extract, which is given in doses of from twenty drops to a fluidrachm four times a day. Codeia is not a new remedy in this disease, having been suggested by Dr. Pavy fifteen years ago. We have found marked results from its use in the case before us. The plan I usually adopt is to begin with half a grain three times a day, gradually increasing the dose, watching its soporific effects,

as well as that upon the pupil. I have given patients in this house as high as ten grains a day, and fifteen grains a day have been given. In this patient, after giving one and one-half grain a day for a few days, we were struck with the smallness of the pupil, but on discontinuing its use for a short time, we discovered that the patient naturally had a very small pupil.

You may ask, have you ever cured a case with codeia? I cannot say I have; possibly, perhaps, because I should be afraid to rely solely upon it, or any other one drug. But such cases of recovery are reported. As is the case with all diseases difficult to cure, there is in addition to those named, a long list which have been put forth as cures. *Bromide of potassium*, also an old remedy, has recently been again brought forward by the French school as peculiarly efficient. I can easily understand how, in a certain class of cases, it would be of value, as those due to hyperæmia of the brain, cases which may be characterized as nervous. We know that emotional causes are often at the bottom of diabetes. Both mental anxiety and physical fatigue have been known to produce the disease, and when purely emotional causes have operated, the bromides may be beneficial, but I have never found them so.

Within the last few days the medical journals have published the treatment of Dr. Clemens, of Frankfort-on-the-Main, by a solution of what he calls *brom-arsen*, which is probably a bromide of arsenic. Dr. Clemens bestows the most extravagant praises upon the remedy; so extravagant, indeed, that I mistrust it, although arsenic itself has long had a reputation in the treatment of diabetes, and not without reason. I shall, however, make an early test of it. He makes it by adding bromine and arsenious acid to glycerine and water, in such proportions that one drop represents $\frac{1}{18}$th grain[1] of bromide of arsenic. Clemens recommends it to be given, along with a selected diet, beginning with one drop three times a day, and gradually increasing until eight or ten drops are given per day. He gives it in a given quantity until it ceases to have an effect, and then he increases it, one drop at a dose, until, as he claims, the disease is cured. He also recommends the use of the *constant current* from twenty to twenty-four cells, one pole being placed at the nape of the neck and the other over the liver. This has been recommended by other German therapeutists. I believe I have tried most of the other numerous remedies recommended in the books for diabetes, but have found them valueless as to specific effects.

Certain it is that we must make different classes of cases of diabetes, and we should never begin treatment until we have as nearly as possible classified our case in accordance with its course. There are cases which can be easily cured by a selected diet; others in whom, while a cure is apparently impossible, the disease may still be kept in abeyance for years, and the patient is practically well. Others again have had sugar in their urine for many years, and seemed not to be seriously affected by it. These are generally stout persons and past middle life. Clemens says, in the article referred to, that the disease in thin, spare persons is generally due to some nervous lesion, and in stout persons to defective assimilation, and in this he is not far wrong. In other cases still, all treatment seems unavailing. The amount of sugar passed may be reduced by treatment, but the patient does not gain any strength. But I believe there are comparatively few cases which, if discovered sufficiently early, are not amenable to treatment. The disease is occasionally overlooked until it has existed for some time. It is well known that it is very much more serious in young persons—say under twenty years of age—than in adults. Yet within the past two years I have known a young girl of twelve years under the care of one of my professional friends recover completely.

Diabetic patients should be careful about permitting any surgical operation. One of the terminations of the disease is gangrene, to which there is a peculiar tendency, and any operation is apt to be followed by gangrene. A year ago a diabetic under my care in this house was blistered upon the foot, and serious sloughing followed.

Cataract is not an infrequent complication, but the operation is not to be recommended for the reasons above given.

[1] Mr. R. F. Fairthorne, with Mr. James T. Shinn, apothecary, corner of Broad and Spruce Streets, Philadelphia, has prepared for me a solution of bromide of arsenic, in the following manner: 77 grains of metallic arsenic in powder are added in small portions to 240 grains of bromine, the latter being placed in a long test-tube immersed in ice-water to prevent too rapid reaction, which is very violent. One hundred grains of the terbromide thus obtained are then dissolved in sufficient distilled water to make ten fluid-ounces. One minim will then contain one forty-eighth of a grain.

Since the above lecture was delivered, I have tried the remedy in two cases, both using an unselected diet. In the one case it could not be borne on account of an obstinate diarrhœa. In the second there appeared to be no effect on the quantity of sugar or urine, but the patient has gained a pound a week in weight for three weeks. The quantity reached was 8 drops a day, or ½ grain.

ORIGINAL ARTICLES.

BRIEF NOTES ON VARIOLA AND VACCINIA.

By EZRA M. HUNT, M.D.,

PRESIDENT OF AMERICAN PUBLIC HEALTH ASSOCIATION.

At the last meeting of the American Public Health Association, in the discussion of a committee report on smallpox and vaccination, the author of this paper, in commenting on the various possible sources of vaccine lymph, enumerated bovine lymph derived from animals which had been inoculated, or which had contracted smallpox. An esteemed member of the Association cautioned against placing a hypothesis so nearly exploded before the unprofessional public. While we claim that there are at present good and perhaps sufficient sources from which to derive vaccine lymph, it is due not less to the art than to the science of medicine that we should know all possible methods of prophylaxis.

We therefore propose to give some facts which seem to us worthy of record, as to the transfer of smallpox to the cow and the subsequent securement of vaccine lymph therefrom. Also to suggest the view that cattle are sometimes inoculated in the act of milking, or in some other way acquire the disease, and that possibly all so-called spontaneous cases of cowpox are but a modified smallpox.

The undenied and undeniable fact that Jenner regarded cowpox as the variolous disease in the cow is well known, and should not be forgotten by those who think he was mistaken. The patient observation of such an authority is of itself of great weight. "Variolæ Vaccinæ" was the name he gave it.

Added to this we long since had the actual results of Mr. R. Ceely, of Aylesbury, whom Simon calls, together with Mr. Marson, "the two highest authorities" in Great Britain (see *Report of Medical Officer of Privy Council*, 1858, p. 8).

The actual fact that both he and afterwards Mr.

Badcock succeeded in variolating thirty-three kine (about 1837), and that this vaccine lymph came long since to be a part of the vaccine supply of England, is indisputable. Although Mr. Ceely succeeded only twice out of a large number of trials, and Mr. Badcock, of Brighton, in only about 7 per cent. of his variolations, yet this does not disturb the fact that they did each succeed. Besides Mr. Ceely's success in the transfer and protection, Mr. Badcock vaccinated over twenty thousand persons from his stock. In fact, much of what we call Jenner lymph is this, for, as Hart states, "many tens of thousands of persons have been vaccinated with lymph generated by passing smallpox through the cow." Lymph from this source, as used in England, is undistinguishable from the spontaneous cowpox lymph.

The Lyons experimenters, in their failure, gave circulation and credence to the idea that Mr. Ceely mistook a variolous eruption for cowpox vesicles. The abstract of facts, as referred to by Ernest Hart in *The Truth About Vaccination*, page 17, shows that Mr. Chauveau and his colleagues were not well informed as to the details of Ceely's experiments. He knew the "tumid papules" full well, and how to distinguish them from the vaccine pustule. (See Robert Ceely's experiments, *Trans. Prov. Med. and Surg. Asso.*, vol. viii. and x., Surgeon-General's Library, Washington.) Dr. Seaton did not doubt the identity of cowpox and human variola (see Seaton's Hand-book). The facts given by Dr. Hardaway in his *Essentials of Vaccination*, 1882, pages 30–34, are confirmative of these views. It is true that at the Brown Institution, Dr. Klein in 1878 failed to produce vaccinia from human variola in thirty-three trials. But Dr. Buchanan, chief of the Local Government Board, in the report for 1879–80 (page 10), says as follows:

"Investigation into the evidences of pathological identity between smallpox and cowpox was made by Dr. Klein during the year 1878–79. Like Gasner, Thiele, and Ceely, he attempted to produce vaccinia in the *calf* by inoculating the animal with human variola; but hitherto his results have so far differed from theirs, that in thirty-three instances his experiments have failed of producing recognizable vaccinia. Yet there is nothing in these observations that can safely be regarded as disproving the transmissiblility of one into the other disease; no doubt the conditions for the transmutation are not yet understood. But there are indications that the affirmative result obtained in a certain proportion of cases by the earlier observers may turn out to be an affair of conditions and circumstances of experiment. Particularly a note appended to Dr. Klein's tabular report (pages 135–142 *cit.*), is of interest in this respect as showing how some unascertained difference in conditions of experiment have yielded in his hands very different results from those of the French Commission in 1865." The success of Dr. Voigt, Supt. Vaccine of Hamburg, whose treatise has been recently translated (see *N. C. Med. Journal*, Dec. 1882), seems to us to settle the question as to the feasibility of producing variola-vaccinia.

In 1830 Dr. Sonderland claimed to have excited variola in cows by enveloping them in infected bed-clothing. A statement made by Dr. Abbott, of Wakefield, Massachusetts, at the last meeting of the American Public Health Association, and to me personally by Dr. Ribble, of Trenton, also seems to suggest the probable transfer in a similar way.

Taking together the views of Jenner, Gassner, Ceely, Badcock, Thiele, Seaton, Voigt, and others, we are surprised that a belief in this source of lymph, and perhaps of this origin of so-called spontaneous cowpox, is not more common. To these, however, we desire to add two reliable testimonies in this country. Dr. Horatio Adams, of Waltham, Massachusetts, in an address entitled "Investigations upon the Subject of Vaccination," read at the annual meeting of the Massachusetts Medical Society, May 26, 1858, uses the following language and gives the following detail of his experiments:

"The fact is probably familiar to all, that within the last twenty years it has been shown that the cowpox can be produced by inoculating the cow with variolous matter. In the October number of the *British and Foreign Med. Review*, for 1839, may be found an account of Mr. Ceely's experiment of inoculating the cow. Soon after this in conversation with a gentleman, whom, in the words of another, I am privileged also to call my teacher, my physician, my friend, James Jackson, it was arranged that the writer should repeat Mr. Ceely's experiment as soon as pure smallpox matter for the purpose could be procured. A brief account of this experiment, the first it is believed that was ever performed in this country with successful results, may not be out of place here.

"On the 11th of January, 1840, I made several punctures with the point of a lancet under the cuticle on the right labium pudendi of two different cows; none of the punctures were sufficiently deep to draw blood. Into each of them was introduced a pointed quill well deluged with variolous matter, and allowed to remain for half an hour.

"On 15th, the punctures were barely visible, but not apparently inflamed.

"On 16th, two of the punctures made on the youngest cow were more distinctly visible; in drawing the finger over them, a slight hardness was felt. None of the other punctures had inflamed.

"*17th.*—These two punctures were more inflamed and a little raised, showing a pearly white, flat top, rather small.

"*18th.*—Punctures larger than yesterday, and each capped with a pearly white, flat vesicle, with centre depressed.

"*19th.*—The punctures (now vesicles) are enlarged, centres depressed.

"*20th.*—Each of the vesicles is nearly four lines in diameter; surface pearly white, flat, with centres depressed, areola not formed, slight crust in centre. This P.M., end of ninth day of disease, punctured one of the vesicles; found cuticle thick, spongy and breaking, like what is seen when a vaccine vesicle is early punctured on the arm. Vesicle distinctly cellular. Transparent lymph oozed from the opening, with which I charged twenty quills. Cow appears perfectly well.

"*21st.*—No material change.

"*22d.*—Vesicle larger and more full, areola forming. Dipped several quills to-day; lymph pellucid. Drs. J. D. Fisher, C. Putnam, and Gregerson examined the case to-day.

"*23d.*—Crust forming rapidly, areola somewhat increased in extent, three-fourths of an inch in diameter, round and regular, and somewhat raised above surrounding skin. Cow eats as usual. From this date disease rapidly subsided; a very dark crust was soon formed. On 27th, Drs. Fisher and Putnam brought me virus taken from a child vaccinated on the 21st instant, with the matter taken from this cow. The vesicle, as they both affirmed, exhibited the characteristic marks of the true cowpox on the sixth day of the disease. Many persons were subsequently vaccinated with matter taken from this cow, and in every instance the true vaccine disease was the result.

"This discovery of the identity, or rather, I should say, this proof of the identity of the vaccine and variolous diseases, is the most important fact observed in relation to the cowpox since the original discovery of Dr. Jenner. For if any doubt should ever arise as to the genuineness of the virus in use, or if it should at any time be lost, as it frequently may be in certain localities, and smallpox makes its appearance, it can be reproduced with certainty by inoculating the cow with smallpox virus."

The large experience of Dr. Adams, and the facts as detailed, leave no doubt as to the reality of his success.

A few months since I had a conversation with Dr. W. C. Van Bibber, of Baltimore, who related to me a series of facts which interested me so much that I asked him to communicate a brief outline by letter. He was so kind as to forward me the accompanying statement, which speaks for itself:

"When I came here in 1845, I found vaccine matter then in the hands of Dr. Peter Chataud, who had been in the practice of medicine here for fifty years. He was one of the originators of vaccination here—and had such enthusiasm that after vaccinating his sons he sent them into the room of a variolous patient. This was in order to establish popular confidence.

"During 1845, '46, and '47, variola was epidemic here. The late Dr. Levin S. Joynes and myself studied it together.

"Dr. William Seward was the "city physician." He inoculated a cow; that is, took matter from an eighth day variola pustule, and inoculated it into the shaved udder of a three year old heifer.

"Dr. Joynes and myself obtained some of this matter, and carefully compared its pustules with the other matter.

"The entire subject here was then much discussed by the old doctors and the young. I was then among the latter.

"I can give some of the points there observed, and can now follow or supplement them by results.

"I had a large acquaintance around the city, and supplied vaccine matter, in crusts at that time, largely. This was then the only source of supply country physicians had. Any one who would supply his professional brethren on call with vaccine matter, was considered a friend in need. I can give some points of information on the matters then under discussion and observation, and which have as yet not been entirely decided.

"Again, in 1852, Dr. Samuel Knight was 'city physician.' An epidemic of variola appeared, not as extensive as that of '45, but still it was bad. Dr. Knight went to the smallpox hospital and took a skein of silk which he charged heavily with lymph from eighth day pustules.

"He had a four years old cow in his own stable on Pearl street. He shaved the udder of the cow and made superficial incisions in its skin. Into these furrows he drew the charged silk, and made a very bold application of the matter. The cow went through a severe disease, and the eruption was very nearly, but not exactly on time; that is, it was not umbilicated on the the fifth day, but continued vesicular until the ninth day. On the tenth, eleventh, and twelfth days the cow did not rise up nor eat. She evidently had a high fever, as shown by her appearance, quick respiration, and thirst. Thermometers were not used then. There were many pustules over the body of the cow; about thirty of them, principally from the udder and belly, were preserved. I selected two for my own use. They were circular; about three-eighths of an inch in diameter; dark mahogany color, with cellular markings, uniform thickness, umbilicated, dry, and hard; having been removed by the finger-nail from the udder on the twenty-third day after the operation. I was the first one to use the virus of one of these crusts. I vaccinated a healthy German five months infant upon the left arm near the insertion of the deltoid in two places. Other physicians saw the case with me during its progress, old physicians and young ones. Amongst the elder ones, I may mention as now living Dr. Ferdinand Chataud, son of Dr. Peter Chataud, and Dr. Thomas Buckler, now living in Paris; Dr. McKenzie and Dr. John Odderman and others, who are dead. They were experienced vaccinators with the original matter which I found here. The vaccinations took in both places, and one proved larger than the other, as is generally the case. But the points were papular to the end of the second day; commenced to be vesicular at the end of the third; umbilicated at the end of the fifth; round and full at end of eighth; and then commencing to be opaque. The areola was large; the fever high on the ninth and tenth days, subsiding on the end of the latter day. The pustules desiccated until the twenty-second day, and when removed, the epidermis beneath them was dry. They had all the marks of a good crust; regularly round, dark color, uniform thickness, umbilicated, cellular markings, dry and hard.

"I then dropped all my old matter and used this, supplying it largely throughout this city, this State, and adjoining States.

"I have never known any one who I vaccinated with this matter to take the varioloid, although I have known numbers to be exposed to the disease.

"I kept this matter alive, active, and largely disseminated for twenty years. About 1871 or '72, M. Lanoix, M.D., from France, came here for the

purpose of introducing the Beaugency matter. He came here from the house of Milhau of New York, and established a vaccine farm near Petersburg, Virginia. My brother-in-law, Dr. Ferdinand Chataud, entertained him. At this entertainment the subject of vaccine was discussed. Lanoix maintained that when the matter was taken from the calf there was no danger of spreading other poisons, as syphilis, scrofula, etc. Unwilling to give up my old matter, which had apparently answered so well, I asked the question "which, as a general thing, is the most healthy animal, a calf or a baby?" It seemed to be the opinion of the majority present that the calf was the most healthy. But, in revenge, I contended that it was a poor doctor who could not select a healthy baby. However, public opinion forced men to give up my matter, although Dr. John Morris and others here urged me to keep on supplying them. But soon a vaccine physician was appointed, the late Dr. Registar, and every one used the "animal" virus. Gradually I have lost trace of my old stock. In this way I have seen, used, and taken great interest in vaccine matter from four different supplies. First, from 1845, the vaccine matter which I found here as used by the older phyicians then practising here, who had obtained it from some original European supply, I do not know where. Then about 1847, I used the Seward supply, but did not give up entirely the original matter until 1852, when I used the "Knight" supply to the exclusion of all others. And since probably 1876, I have used none other than the "animal" matter as propagated by Dr. Martin and others from the Beaugency supply. Dr. Chataud did not like the matter as supplied by Dr. Lanoix, nor did I.

"I can get all the facts, dates, and observations to fill up this rough sketch, my Dear Doctor, if they will be of any use to you or others, and meanwhile believe me to be, with much respect," etc.

In the light of recent facts such as have been brought to notice by Pasteur, Koch, and others, and of the embarrassments which may yet come to attach to the production of lymph from "spontaneous cowpox," about which there is still dispute whether any case has occurred in this country, it is not unwise to put on record these facts.

Even if the first lymph from a variolated cow might be over-severe, or if there might be a risk of mistaking the "tumid papules" of the variola for the lymph-bearers of vaccinia, it is not unlikely that the repetition from calf to calf might furnish an attenuated lymph sufficiently protective. If so, would it not be purer in its origin, and at the same time furnish us a mode of renewal of supply more uniform than the present dependency upon stocks already far removed and probably not now propagated in distinct lines?

We are not of those who doubt the reality of present protective methods, or who would advocate resort to experiments of this character, except under some special State or Government sanction or direction. But fealty to science, to art, and to series of facts thus authenticated, makes it proper to put on record this testimony. All the more because of the great experience of Voigt in bovine lymph, and of the important opinion which he gives when he says, "As a zealous promoter of animal vaccine, which has become indispensable to me, I will not insist again upon its usefulness; but, in conclusion, I will point out that it should be *regenerated betimes* in order that it may maintain its full energy. *To me it seems that animal vaccine* needs such regeneration quicker than the humanized."

TRENTON, N. J., February 14, 1883.

A CASE OF ŒDEMA UVULÆ, THREATENING THE LIFE OF THE PATIENT.

BY CHARLES H. CARTER, M.D.,
OF CHICAGO, ILL.

A FEW weeks since I was consulted by Mr. N., æt. 19, for a "sore throat." This was about 9 A.M., and he had felt no inconvenience till, upon rising that morning, he experienced considerable difficulty and pain in swallowing his breakfast; otherwise, he felt, to use his own phrase, "all right."

Upon examination I found a moderate congestion of the whole post-oral cavity. Tonsils and soft palate slightly swollen, the mucous membrane dry and shiny. Temperature 99½°; pulse 84; tongue clean but dry, and some thirst. No headache or other pain. Had had no chill, nor chilly sensations. Slept well the preceding night, and, notwithstanding the pain caused by the act of deglutition, he ate his breakfast with the usual relish. In short, he had no subjective symptoms indicating that he had "caught a cold," other than the soreness in the throat, and had undergone no unusual exposure.

Calling it a simple pharyngitis, I ordered a seidlitz powder, a solution of potassium chlorate as a gargle, and a flannel around the neck. Knowing him to be of good habits, and he being a furniture upholsterer, working indoors, I had no hesitation in permitting him to continue work as usual. I advised him to consult me again at the same hour the following day, and thought no more of the case, until one o'clock next morning I was aroused by an anxious ringing at my doorbell, and upon attending to it, I was informed by an almost breathless messenger that Mr. N. was dying—choking to death. I subdued a half-uttered "impossible!" and not waiting for any further explanation, and thinking of œdema glottidis or an unusually sudden and excessive swelling of the tonsils, etc., I dressed myself with all possible haste, and was soon at the residence of my patient. A truly terrible spectacle presented itself to my view. He was certainly struggling against impending suffocation, and that with fearful odds. The location of the obstruction, however, was at once apparent, for he was sitting with his head bowed forward, holding the stem of a tobacco-pipe in his mouth, breathing *through* it. A glance into his mouth revealed the cause of his dyspnœa. His uvula was so large that it completely filled the whole inter-tonsillar space and pressed hard upon the dorsum of the tongue, and as he could not breathe through his nose, the uvula and palate evidently closed that passage also.

The œdematous uvula resembled a bladder filled with clear water, and was so distended as to be

almost transparent. I quickly punctured it at several points on its anterior surface with a bistoury. This lessened its size in that portion, but had no effect on the unpunctured sides. Passing a spatula under it and turning it up edgewise, gave him plenty of breathing room, and his dyspnœa was at once relieved, the air then having ready access to the glottis, which was obviously unaffected. Drawing the uvula forward from each side with a tenaculum, I successively drained its lateral and inferior surfaces. He had now no further use for the spatula, and felt comfortable, but almost exhausted. Now passing a loop of stiff wire behind the uvula and drawing it forward, I riddled the posterior surface with the point of the tenaculum, and finally I transfixed the body of the uvula twice from before backwards with a small tenotomy knife. This being done, he could respire through the nose with ease.

All this scarification and transfixion drew only a few drops of blood, and were almost painless.

The uvula now hung in a flabby, irregular, wrinkled mass, apparently having lost all contractility, its lower extremity lying upon dorsum of tongue, but leaving a small space open on each side. The tonsils were more swollen, but paler, than on the morning before. Temperature now 102°; pulse 108, and weak.

Deeming an astringent indicated, I added tannic acid, gr. x to ℥j, to his chlorate of potassium solution as a gargle, and left him happier than I found him.

A bilateral suppurative tonsillitis followed, but its course was thenceforward typical, and ended in complete recovery in two weeks, under the use of warm poultices, externally and my usual "let-alone" treatment of such cases, internally. I have rarely found it necessary or even advisable to resort to incision to expedite the evacuation of the pus, nature, in most cases, being surgically self-sufficient.

I have frequently noted a moderate degree of œdema uvulæ in connection with pharyngitis or tonsillitis, but never before of such prominence as to be more than a minor accompaniment. In this case it was the disease *per se*, and the other pathological phenomena the complications.

The above case is, in my experience, unique, and judging from the very slight references or even silence of authors on diseases of the throat, concerning œdema uvulæ, such cases must be very rare. My patient was thoroughly convinced that his time had come, and this also was the conviction of all the anxious spectators of his struggle for life. He stated that the swelling in his throat had gradually increased after seeing me in the morning, but he had had no difficulty in breathing through his nose till about half an hour before sending for me, and this increased rapidly till that source of oxygen was also cut off, and then, in some way or other, in his desperation, he seized the pipestem and forced the end of it into his throat, and felt the air pass through it, though in very inadequate quantity, and held it there till I arrived. I have no doubt that by means of this simple though much abused instrument, he was rescued from being asphyxiated, before help could be procured. He said he did not think of the pipestem being a *tube* when he inserted it into his mouth. Did not know what was his object in using it. In fact, did not remember anything about the pipestem up to the time when he felt the air passing through it. So much in favor of the clay-pipe. This one was not made in vain.

The above case being interesting and novel to me, I have thought it worth relating for the readers of The Medical News. No doubt some will be as much surprised as I was, to know that so insignificant a part of the economy as the uvula may *thus jeopardize life*. Others may have seen similar cases. If so, I for one, would be gratified to see them reported.

1198 Milwaukee Avenue.

MURIATE OF QUININE.

(QUININÆ HYDROCHLORAS, U. S. P., 1880.)

By JOSEPH MIXSELL, M.A., M.D.,
of Philadelphia.

Custom and habit together have bound each successive generation of physicians to the exclusive use of certain combinations of drugs whose choice was originally the result of accident or commercial convenience.

This assertion will be studied in the present instance in its bearings upon the medicinal application of the principal alkaloids derived from cinchona; as of these, quinine has deservingly occupied the most prominent position in therapeutics, its selection, as an example, will be assumed as most proper.

This substance has been quoted ever since its discovery and isolation—in combination with sulphuric acid, in its familiar form as the sulphate of quinine—by all writers with but few exceptions, to the extent of obtaining tacit recognition as the standard or normal state of the drug, few reporters ever specifying the salt by title; and several high authorities confirming this usage by explicitly calling attention to the fact that whenever the expression quinia (quinina, 1880) is used the reader will understand that the sulphate of quinia is intended.

The writer was led to the examination and employment in practice of the combination of hydrochloric acid with this and associated alkaloids, through the ideas suggested by observing that the valuable and interesting experiments of E. Buchanan Baxter, M.D., London ("Action of Cinchona Alkaloids, etc., on Bacteria," *Practitioner*, Nov. 1873), were conducted exclusively with solutions of the hydrochlorates of the alkaloids. Reference to the standard works on pharmacology in general use in this country, showed complete indifference on the part of authors and editors on this subject, until the publication in 1879 of a portion of Phillip's *Mat. Med. and Therapeutics* ("Wood's Library Standard Medical Authors," N. Y.), where brief allusion is made to the experiments of Dr. Baxter—in their microscopical and toxicological bearings, without suggesting their possible importance in the light of therapeutics.

The *National Dispensatory* (Stillé & Maisch, second edition, Philadelphia, August, 1879), after

devoting over fourteen pages to the consideration of quinia (quinina) as a sulphate, gives just as many lines to the description of the hydrochlorate—hidden from observation by association with the other little known salts under the caption "valerianate of quinia." The *United States Dispensatory* (Wood & Bache, fourteenth edition, Philadelphia) merely alludes to the existence of these salts, in the same category with the fanciful combinations, as the lactate, arseniate, etc., without a word of commendation.

The *Pharmacopœia of the United States*, sixth revision, introduces this salt for the first time as an officinal along with the sulphate, bi-sulphate, hydrobromate, and valerianate, and the uncombined alkaloid; from the purely pharmaceutic character of this work in its present state of incompleteness, no information is obtainable save that of chemical characteristics. The impressions of the writer, then, are based entirely upon the experience obtained by the opportunities afforded within the necessarily limited field of private practice, and this under the serious obstacle of an almost prohibitory price demanded by the manufacturers and dispensers of the substance; and it has only been by direct persistent personal effort that at the present time this salt is placed within the reach of patients in moderate circumstances. In this connection he is compelled to refer to the unfair discrimination on the part of the large producers of these salts in favor of the commercial sulphate and its associate the bi-sulphate. That this is entirely based upon commercial prejudices is beyond question, the writer having received the most respectful attention in his direct application to all the large manufacturers of the derivatives of cinchona bark in the United States, but with such moderate success in obtaining concessions in price as to dishearten him as to the use of further individual effort. The therapeutic harmony of this combination of either of the cinchona alkaloids will occur to the mind of the careful prescriber as of peculiar fitness; but not upon this alone does the writer urge the claims of the muriates, which may be enumerated as follows:

I. *The advantage of superior alkaloidal strength;* II. *More rational therapeutic combination;* III. *Prompt action—due to speedy absorption;* IV. *Extensive range of pharmaceutic compatibility;* V. *Ready solubility without aid of acid;* VI. *Toleration by stomach or rectum.*

The comparative richness in the basic element is thus well shown.

The theory of its composition, as formulated in the *United States Pharmacopœia* of 1880—$C_{20}H_{24}N_2O$, HCl_2H_2O, requires a percentage of quinine of 81.71; that of the sulphate being 73.5 (*misstated on page 1212 of the National Dispensatory, second edition, as 85.0*), and the bi-sulphate 59.1, a difference in favor of the muriate of respectively 8.21 and 22.6 per cent.

By actual analysis made with great care and in every instance verified by the process known as "acid determination"—whereby the most common source of error in the estimation of quinine strength is avoided, that of the invariable loss in washing the precipitate whenever the "direct process" is employed (by the kind assistance of Edward Hart, Ph.D. [J. Hopkins], Professor of Analytical Chemistry, Scientific Department Lafayette College, Easton, Pennsylvania, 1880)—it was found that an actual alkaloidal yield of from 81.4 to 84 per cent. was obtained, probably due to the loss of some of the water of crystallization.

The identity of therapeutic applicability possessed by quinine and hydrochloric acid will be questioned by few, both exhibiting azymotic powers in the highest degree.

The quality of readiness of absorption is probably its most valuable attribute. Where promptness of action is desirable, as in the anticipation of the chill in the pernicious form of malarial toxæmia, or where, through the unfavorable condition of the oral and gastric surfaces, due to the accumulation of epithelium and inspissated mucus, the less assimilable forms of quinine do not obtain access to the absorbing tissues, the muriate, from its relations to the fluids of the body, will obtain entrance to the circulation to a degree surprising to those unfamiliar with this peculiar power.

Its chemical relationships give it a wider range of pharmaceutic combination than the sulphates possess.

In the familiar instance of the almost classic prescription of the alcoholic solution of chloride of iron, alone or with potassium chlorate, with quinine, which is usually specified as in the form of sulphate, a most disagreeable and unscientific result is obtained, that of a precipitate of a portion of the iron in the form of a gummy sediment—a basic sulphate, similar to the styptic salt of Monsel; it is true that this is often avoided by the skilful pharmacist, by converting the quinia into an acid salt by the addition of a few drops of hydrochloric acid before combining it with the iron solution, but this is not to be relied upon, and may result in the dispensing of an almost corrosive mixture in place of the neutral one intended. The substitution of the muriate for the sulphate of quinine will obviate this difficulty; so too with potassium iodide or bromide, although owing to the presence in the commercial salts of a small amount of potassium carbonate, the addition of an amount of hydriodic or hydrobromic acid is needed to ensure the absence of precipitation.

Ready solubility in watery or alcoholic fluids, nearly equal to that of the much advertised bi-sulphate, far greater than that of the commercial or neutral sulphate. Although much stress has been laid upon the great advantage possessed by the acid sulphate over its older companion, clinical experimenters seem to have overlooked the counterbalancing disadvantages of increased dose, and, until the bubble was burst in the "wars of the pill-makers," increased cost. Although the writer's lack of time and opportunity has not permitted him to apply other than clinical tests to the comparison of the muriate with all other forms of quinine administration, he is still convinced of the equal solubility of this salt in the gastric fluid, as shown by the very simple and unquestionable test afforded by the production of cinchonism. In the practical employ-

ment of this salt, it will be found that the addition of a few drops of strong alcohol to a gramme of the muriate will render the crystals so permeable that the addition of a very moderate amount of water will effect a perfect solution—this in view of the effects shown in the paper of Dr. Baxter, *loc. cit.*, upon bacteria growth, has led to its trial as a local application in diphtheritic angina, by brushing the exuding surface every hour or two with a saturated solution prepared as mentioned, or with the addition of aqua chlorinii, with apparent advantage in limiting the disease to its original locality. The stomach will tolerate this, if properly administered, when other salts of quinine are promptly ejected.

The absurdity in the practical work of medicine, of compromising the activity of medicinal agents, by so combining them as to procure immunity from taste at the expense of solubility in the fluids of the stomach, is nowhere so glaring as in the various devices by which both practitioner and pharmacists have from time to time conspired against the welfare of their patients and patrons, in their dealing with this life-saving drug. The tannate will represent the most aggravated instance of this misconception; however valuable where its *acid* constituent is the one needed, as a means of administering quinine it is irrational and unscientific. Nausea is not always, nor even often, produced by taste, and when the stomach is irritable and disposed to reject anything placed within it, it will be found least apt to do so with *neutral* solutions. In the bilious remittents found along the water-courses draining into the Lehigh Valley—when the remission was so feebly separated from the pyrexia that the whole intestinal tract was in a state of exalted sensibility throughout the entire cycle of twenty-four hours, with rejection of everything administered as food or medicine—this combination of quinine has been successfully administered (in sufficient doses to obtain its apyretic influence), dissolved in freshly tapped champagne, without a word of complaint from the patient. With an experience of nearly twenty years spent in the dispensing and prescription of this remedy, in its several forms, the writer is disposed to regard as the ideal mode of its administration that of "*capsulation*" IN THE DRY WAY, *i. e.*, while yet in the crystalline state, *without* the preliminary operation of forming a pill mass; the latter is chiefly objectionable on account of the usual addition of some gummy excipient, which speedily hardens, rendering the salts less soluble than when discrete in the crystalline state, often ensuring gastric or enteric disturbance through mechanical irritation from slow solution.

If given in champagne or other spirituous or syrupy vehicle, a solution should be prepared as directed for topical application before addition, to insure complete admixture. The rectum will most readily tolerate and promptly absorb this salt, which can be introduced by enema of simple watery solution, or by suppository—the *hollow* variety affording the simplest means of placing it within reach of the absorbing tract.

In concluding this very incomplete *résumé* of the reasons entitling this little-used group of salts to our earnest consideration, the sole objection to their frequent substitution for those in common use—that of costliness—will bear a parting word. That this is not an insuperable obstacle may thus be shown:

The main cost to the makers of all the cinchona salts is that of the extraction of the alkaloids from the bark; so that it may be fairly assumed that the cost of either of the salts of quinine to the manufacturer would be principally that of the relative amounts of the alkaloid required to produce a given weight of any one of them. Admitting the correctness of this proposition, if the cost of producing one ounce of the commercial sulphate of quinine, requiring the outlay of 73.5 per cent. of its weight of the alkaloid, is at present somewhat less than $1.80, the cost of any salt would bear a definite relation to this fundamental representative. Thus, in estimating the value of the muriate, 73.5 : $1.80 : : 81.17 : $2.00. Or, as to the bi-sulphate, 73.5 : $1.80 : : 59.1 : $1.45.

To divest this statement of all complexity, it will suffice to claim that if the manufacturer can produce and sell at a profit, an ounce of a combination of which the costly element is represented by 73.5 parts to the hundred, at $1.80, a second combination containing in every hundred parts 81.7 of the same costly ingredient, should be offered at the relative price of $2.00, or a third combination in which there is contained only 59.1 per cent. at its true value based upon its relative composition, $1.45.

It is, however, due to the makers of these salts to admit that the cost of material is not absolutely the only factor in the disparity of trade and therapeutic value. By reason of the vast consumption of the sulphates their crystallization is effected on so extensive a scale that labor and apparatus are both reduced to a minimum of expense; while that which to us, as therapeutists, constitutes a great advantage—the extreme solubility of the hydrochlorates—is commercially a disadvantage, rendering their separation from the mother-liquor tedious and difficult, demanding a higher grade of intelligence on the part of those conducting the operation, hence enhanced cost of labor; still another impediment to parity in expense of production is found in the character of the material from which the vessels for evaporation, etc., are made, porcelain or wedgewood-ware alone being suitable.

A portion of this cause of expense can be dispensed with by the presentation of the salt in its amorphous form, found by Kerner, of Frankfort (*Practitioner*, March, 1873), to be equally active, if not superior, to the crystallized form. This is not procurable in this city, in its isolated form, the nearest approach to it being the "muriate of quinquinia," of "The Charles T. White Co.," of N. Y., a residual product of quinine manufacture of variable composition, containing always about 20 per cent. of crystallizable quinine.

The well-known house of W. H. Schieffelin & Co., of New York City, have, at the suggestion of the writer, included the muriate of quinine in their list of gelatine-coated pills.

Through the enterprise of Messrs. Keaseby &

Mattison, of Philadelphia, the hydrochlorate of cinchonidine was placed before the profession in December, 1880; but, from the extreme solubility of the salt and the resultant difficulty of presenting it in a crystalline state, its costliness proved a bar to its general adoption.

The hydrochlorate of cinchonine is made in large quantities, and has been sold for a long time; not, however, without the suspicion of entering largely into the adulteration of the sulphate of quinine, which it closely resembles, at the hands of fraudulent pill-makers and jobbers, whose sales are made in the remoter portions of our country.

With a favorable impression of the utility of the "unbleached or hospital quinine," only presented as a sulphate, the writer suggests its production as a hydrochlorate, that the most needy may not be debarred from the use of the most active remedies.

Finally, no credit is claimed by the writer for his comparatively superficial, although always practical, researches in this field. The paper is placed before the readers of "THE NEWS" that it may be tried as to its worth, and save others the labor and expense its preparation incurred.

NOTE.—The *United States Dispensatory* (Wood, Remington, and Sadtler, 1883), just issued, confirms the writer's assertion that medical authorities, as a rule, show positive lack of acquaintance with the theoretical as well as practical superiority of the hydrochlorate over the sulphates; this combination being dismissed by the above-named compilers with a careless remark as to its intrusion among the officinals without good reason.

No excuse can be offered for so glaring an omission; simple inquiry of either of the great quinine-producing establishments of this city would have shown that since the earlier efforts of the writer to familiarize the profession with the usefulness of this and other muriates [annual meeting Lehigh Valley Medical Association, Bethlehem, Pa., August, 1880, reported in *Trans. Med. Soc. of Penn.*, vol. xiii., part 2], the salt is in active demand, hundreds of ounces being produced where formerly it was rarely called for.

822 N. TWENTY-FIRST ST., PHILADA., Jan. 1, 1883.

HOSPITAL NOTES.

ST. JOSEPH'S HOSPITAL, PATERSON, N. J.

Service of G. H. BALLERAY, M.D.

SUB-PERITONEAL HÆMATOCELE.

(Reported by JAMES W. SMITH, M.D., House Surgeon.)

A CASE of sub-peritoneal hæmatocele was admitted into the hospital in December, 1881. The patient was 26 years of age, the mother of four children, the last two of which were twins, and were born in April, 1881. The menses appeared during the last week in October, reappeared in three weeks, and after being absent one week, returned, accompanied by pain in the back, and continued up to the time of her admission to hospital. Two weeks before admission, a substance was expelled from the vagina, which, according to the description of the patient, "resembled the lining of a chicken's intestine."

On admission, the patient was in the following condition: Pulse 112, very feeble, face pale, lips blanched, abdomen tympanitic, temperature normal. The discharge from the uterus resembled lochia, and was somewhat offensive. Physical examination revealed a tumor, rising about three inches above the brim of the pelvis, globular in form and regular in outline. This tumor was situated to the left of the median line; several other large masses, of irregular outline, could be felt through the thin abdominal walls, at different points in the abdomen. Per vaginam, the cervix uteri was found crowded over to the right, and pressed up so closely against the pubes, that it was reached with difficulty. When the os was reached, it was found patulous, admitting the index finger easily for some distance. By conjoined manipulation, the smooth globular tumor felt above the brim of the pelvis, was found to be continuous with the cervix. To the left of, and posterior to the uterus, a large, smooth, slightly fluctuating tumor could be felt, which was continuous with the uterus, and but slightly tender to the touch.

The patient being in a very critical condition, a consultation was called, the day after she was admitted to the hospital, with a view to obtaining the opinion of the staff as to the nature of the case and the advisability of an operation. The opinions of the members of the staff differed widely as to the nature of the case, and, consequently, as to the best treatment to adopt. Drs. Balleray, Van Riper, and Calvin Terriberry, were of the opinion that the case was one of extra-uterine pregnancy; while Dr. Marsh thought it might be a case of malignant disease,[1] and Dr. Quinn believed it to be a morbid growth connected with the uterus and bound down in the pelvis, but in no way connected with gestation.

It was finally decided to aspirate the fluctuating mass in the vagina. The aspirator needle was plunged into the mass, but nothing was obtained but a small quantity of dark, bloody fluid, containing numerous small, dark coagula. This caused Dr. Balleray to modify his diagnosis. He then expressed the opinion that the case was one of sub-peritoneal hæmatocele, due to rupture of the Fallopian tube, at its lower part, at an early stage of tubal pregnancy, and an escape of its contents, together with a considerable effusion of blood, between the layers of the broad ligament; and some inflammatory exudation in the surrounding tissues. The patient was put to bed, perfect quiet ordered, with nourishing liquid food and some stimulants; the vagina to be syringed out twice daily with hot water, followed by a weak carbolic lotion. On the fifth day after the aspiration, the pulse became more frequent and the temperature began to rise.

On the seventh day, Dr. Balleray observed, while making a digital vaginal examination, that the discharge was increased in amount, and more offensive than usual. He therefore suspected that a portion of it came from one of the openings made with the aspirator. The following morning the patient's pulse was 120, temperature 103.4°. She was placed on the operating table in Sims' position, and Sims' speculum was introduced, and the posterior vaginal wall retracted. It was then found that a grumous, dark, bloody, offensive discharge was issuing from the opening made with the largest aspirator needle. A free incision was made into the softest part of the tumor with a bistoury, when about two ounces of thick, dark, grumous, bloody

[1] Dr. Marsh formed this opinion from the feel of the hard, irregular masses before referred to, which were to be felt in different portions of the abdomen. Dr. Balleray, however, thought that these masses were fecal accumulations, and this opinion proved to be correct, as they were subsequently removed by repeated large enemata containing ox-gall.

fluid escaped; together with considerable débris of blood-clot. The patient was then put to bed, and the nurse directed to continue the vaginal injections.

The following morning the temperature was 102°, pulse 108. The patient was again placed on the table, a soft catheter introduced into the opening made with the bistoury the previous day, and a weak, warm carbolic acid solution was injected into the cavity. The catheter passed in to the depth of three and a half inches. By means of the injections, dark, broken-down, offensive coagula were removed. The injections into the cavity were repeated daily, and the vaginal injections continued. On the fourth day after the operation, some exceedingly foul-smelling material, resembling a mixture of pus and débris of partially organized blood-clot, was removed by the injection. After this the temperature fell to 100°, and never rose again above that point. The injections were resorted to daily for nine days, after that only every second day for some time longer.

At the end of three weeks the cavity had contracted so that it would not hold a half ounce of fluid; the swelling previously felt in the vagina had almost entirely disappeared; the cervix was in its normal position, and the fundus no longer to be felt above the pubes. At the end of four weeks the artificial opening had closed; the patient's appetite was good, the temperature and pulse normal; in short, convalescence was fully established. The patient returned to her home in Passaic city, and is now in good health.

The interest of this case attaches to the diagnosis. What was the cause of the hæmatocele?

If it was due to rupture of the Fallopian tube at an early stage of tubal pregnancy, then the woman ought to have had some of the symptoms of pregnancy previous to the accident, but the fact is that these were entirely wanting. She ought also to have manifested some symptoms of shock at the time that the rupture occurred, but no such symptoms were observed. On the other hand, what other condition than that to which they were attributed could have given rise to the enlargement of the uterus, the patulous os, and the discharge of a deciduous membrane? The treatment was justified by the result. Those who saw the patient were convinced that she recovered *in consequence* of the treatment, not, as very often occurs, in spite of it.

MEDICAL PROGRESS.

The Relation of Micro-organisms to Tuberculosis.—Mr. W. Watson Cheyne, in a report to the Association for the Advancement of Medicine by Research, holds that when the tubercle-bacilli reach the alveolus of a lung which is in a suitable condition for their growth, they develop in the epithelial cells lining the alveolus. This alveolus becomes filled with cells, neighboring alveoli become affected, and the same process goes on in them. The further result will depend on the number and growth of the bacilli, and on whether the patient is a good soil for their development. If they develop well, we have caseous pneumonia; if they grow slowly and with difficulty, we have fibroid phthisis. In the former case, the alveoli become early distended with epithelioid cells; inflammation of the walls of the alveoli ensues; the epithelioid cells soon undergo caseous degeneration; and the presence of the masses leads to atrophy and sloughing of the walls of the alveoli. Infection of neighboring parts of the lung occurs by continuity, and also by partial coughing up, and re-inhalation of the bacilli into other parts of the lung. In this rapid phthisis, fibrous formation around the alveoli only takes place imperfectly, and the lung rapidly breaks down.

In the case of fibroid phthisis, the bacilli are few, and grow only with difficulty. Thus fibrous formation occurs extensively, and giant-cells are entangled in this fibrous tissue. In parts, however, the process may be more rapid, and these cheesy masses are found, which may lead to breaking down of the lungs and the formation of cavities.—*British Medical Journal*, March 17, 1883.

The Antipyretic Action of Kairin.—At the meeting of the Berlin Medical Society, held February 21st, Prof. Ewald demonstrated some temperature curves, which proved the antipyretic action of kairin, as claimed by Filehne. In the case of a phthisical patient with chronic gastric disturbance the hourly administration of kairin in seven grain doses reduced the temperature below normal: when the administration of the drug was stopped, the temperature again was elevated above the normal, to be again reduced by the re-administration of the drug. Guttmann could also confirm this evidence as to the antipyretic action of kairin in the instance of a case of bilious pneumonia, where a similar result followed the administration of the drug.—*Deutsche Med. Woch.*, February 28, 1883.

Thymol as an Antipyretic.—Fiori has made investigations on the action of thymol on the circulation of febrile and non-febrile patients with diseased or sound hearts (*Centralblatt f. klin. Med.*, No. 2). The points that received attention were the temperature, the pulse, the blood-pressure, and the respiration. Three to four gramme doses lowered the temperature and the frequency of pulse and respiration, without exercising any injurious action on the contractile power of the heart. The arterial blood-pressure, as measured by Basch's apparatus, was found to be invariably raised.—*Med. Times and Gaz.*, March 3, 1883.

Azoospermia in Health and Disease.—A. Busch has examined the condition of the spermatozoa, in different ages, in the testicles, epididymis and the vasa deferentia, with the following results:

	Spermatozoa. None.	Few.	Many.	Total.
Cases of sudden Death,	—	3	4	7
Acute Diseases,	2	3	9	14
Pulmonary Phthisis,	14	20	8	42
Chronic Diseases,	11	13	13	37
Total,	27	39	34	100

As causes of the absence of spermatozoa, Busch mentions faulty development of the testicles, local causes, general causes, and senile atrophy. The average weight of the testicle and epididymis is 14.3 grammes, while its relation to the general body weight is as 1 : 1755.—*Central. f. d. Med. Wissen.*, February 24, 1883.

Operation for Umbilical Hernia.—Dr. Dejean, communicates an interesting case to the *Bulletin de Thérapeutique*, in which he performed an operation for an umbilical hernia, as large as a fist, which occurred in the person of a woman twenty-two years of age. Signs of strangulation had manifested themselves during five days, when the operation was performed, under Listerian precautions "as far as possible." The hernia, as usual in such cases, was found to consist of omentum and intestine, the former placed in front. The reduction of the intestine was accomplished, as recommended by Richer, by dilatation of the ring instead of by its incision, and the portion of the omentum which obstructed the reduction was removed. The wound healed readily; and on the twelfth day the patient was able to leave her bed.—*Med. Times and Gaz.*, March 3, 1883.

TWO CASES OF PERFORATION OF THE ŒSOPHAGUS.—KLAAR reports the following cases:

1. A woman, aged 32, swallowed a piece of bone, and an attempt was made to push it down into the stomach. Severe pain in left half of the chest resulted, and death occurred in a few days with symptoms of pneumothorax. The autopsy revealed a perforation of the œsophagus, with consecutive pleurisy and pneumothorax.

2. A man, aged 41, swallowed a small piece of wood which was enclosed in a sausage; the fragment remained in the œsophagus, and in fourteen days death resulted from severe hemorrhage from the mouth and anus. The autopsy showed that the splinter of wood had been arrested in the œsophagus at the level of the bifurcation of the trachea, and that one end had perforated the aorta.—*Centralb. f. d. Med. Wissen.*, February 24, 1883.

NEPHRECTOMY IN ITALY.—DR. SPADARO reports (*Gazetta degli Ospitali*, February 18, 1883) that five operations for removal of the kidney have been performed in Italy: the first by Urbinati, of Cesena, the second by Raffa, of Rovigo, the third by Clementi, of Catania, the fourth by Novaro, of Turin, and the fifth by D'Antona, of Naples, the last three being successful. Prof. D'Antona's operation was performed December 20th, on a married lady, aged twenty-six, by a curvilinear incision in the left loin. Pus was found around the kidney, which was changed into a bag containing matter. The artery and vein were secured in one ligature, the ureter in another, while a third ligature on the proximal side of the others included all those structures. Perchloride of iron was applied to the stump, and iodoform sprinkled into the wound, which, on the suggestion of Prof. Palasciamo, was not sutured. According to the last report (twenty-fifth day after operation), the wound was granulating rapidly, and the patient progressing to complete recovery.—*Lancet*, March 10, 1883.

DILATATIONS OF THE ABDOMINAL VEINS.—At a recent meeting of the Medical Society of Bonn, DR. LEO presented a man with immense enlargement of the veins of the abdominal walls, which had developed in the course of a few months. The enlargement commenced in the right groin and extended in two snake-like coils to the border of the ribs; on the left side, and in the middle line of the abdomen there was also a single strand of similarly enlarged veins. The affection suggested the well-known *caput Medusae*, although it did not surround the umbilicus; although the etiology is obscure, it is probable that the condition is caused by compression of the portal vein, though the liver is normal in size.—*Berliner klin. Woch.*, March 5, 1883.

ANEURISM OF THE ORBIT TREATED BY LIGATURE OF THE CAROTID.—In the *Vratch*, 1882, No. 13, there is a very interesting clinical lecture by Professor N. V. Sklifosovsky, of Moscow, on a case of idiopathic aneurism of the right orbit in a male non-syphilitic patient, aged 45, of moderately alcoholic habits, with chronic arteritis. All symptoms of the aneurism, viz., pulsating exophthalmos, œdema of the lids, dimness of vision, headache and earache, noise in the head, had been developed quite suddenly, no history of injury having been obtained. On examination of the patient about six weeks later, there were found, in addition to the above symptoms, total loss of vision, insensibility and opacity of the cornea, dilatation and immobility of the pupil, anæsthesia of the lids and right half of the forehead, complete immobility of the eyeball, pulsation on pressure of the latter, blowing noise (like that of a pair of slowly working bellows) heard over the right eyeball and the corresponding temporal, parietal, and occipital regions, and disappearance of the subjective noises on compression of the right carotid at the level of the cricoid cartilage. The author diagnosed rupture of the atheromatous right internal carotid within the cavernous sinus, under the influence of some accidental increase of arterial tension. After the failure of seven days' treatment by compression of the carotid (ten minutes every hour), and low diet, the artery was tied at the level of the cricoid cartilage. Four weeks later the state of the patient was found satisfactory; the opacity of the cornea, the œdema of the lids, and the exophthalmos had disappeared almost completely; the eyeball became movable (abduction, however, was paretic); cutaneous sensibility was restored, and headache had ceased. The loss of vision, however, remained as entire as before the operation. Within five days after the ligature, there began to be developed a cataract of the right lens.—*London Medical Record*, March 15, 1883.

DRAINAGE OF THE ENTIRE MEDULLARY CAVITY.—BLECKWENN reports a case of chronic, diffuse osteomyelitis of the humerus in which resection of the head of the bone was performed, and drainage of its shaft accomplished by trephining the lower diaphysis and removal of the medulla. Recovery, with a useful arm resulted.—*Centralb. f. d. Med. Wissen.*, February 24, 1883.

TREATMENT OF HYDROCELE.—DR. MELILLO, of Rio de Janeiro, recommends (*Il Morgagni*, December) as an improved method of treating hydrocele the employment of a small syringe capable of holding ten grammes, graduated into ten equal parts, each capable of holding a gramme of a mixture of equal parts of chromic acid and water. After the puncture with the trocar has been made, and the liquid begins to flow out, the point of the syringe is immediately substituted for the trocar, before any more of the liquid escapes, and two grammes of the dilute chromic acid are slowly injected for every eight grammes calculated to exist in the tunica vaginalis. After five minutes the syringe is withdrawn, and nearly all the liquid allowed to escape, after which the canula is withdrawn. Any other irritant may be substituted for the chromic acid, and any sized syringe may be used; the object being only the securing the liquid of the hydrocele as a menstruum for the irritating substance employed.—*Med. Times and Gaz.*, March 3, 1883.

AUSCULTATION OF THE RESPIRATORY MURMUR IN THE ABDOMEN AS A MEANS OF DIAGNOSIS.—PROF. CANTANI claims that auscultation of the respiratory murmur over the abdomen will enable the separation of intestinal meteorism from pneumo-peritoneum. In the latter condition the respiratory murmur can be heard over the entire abdomen, while in the former it does not extend further than the region of the stomach.—*Centralb. f. d. Med. Wissen.*, February 24, 1883.

GASTRO-ENTEROSTOMY.—DR. FISCHER (*Deutsche Zeit. f. Chirurg.*, Bd. xvii. 5, 6), of Strasburg, describes the case of a woman, aged 31, who, a year before admission to hospital under his care, had been a patient of Professor Freund, who had removed the uterus for fibro-myomatous disease. She had all the symptoms of cancer of the pylorus, and Lücke decided upon attempting resection. The stomach was washed out for twelve consecutive days, and on the twelfth the abdominal cavity was opened, but the pylorus was found intimately adherent to the pancreas and other adjacent structures, so that resection could not be performed. The pylorus, was, therefore, simply laid open and

united to the abdominal wound, as in an ordinary gastrostomy. The operation was performed without spray, and the aperture in the abdominal wound that was united to the opening in the pylorus was dressed with iodoform and covered with thymol gauze. In thirty-seven days the patient was discharged. Since her dismissal from hospital she has been able to take light nourishing food, and remains free from any tendency to vomit.—*London Medical Record*, March 15, 1883.

The Virus of Charbon.—At a recent meeting of the Société de Biologie, M. Franck read a note by MM. Arloing, Cornevin, and Thomas relative to the different modifications produced in the virus of charbon by various physical and chemical agents. The resistance of dried virus is very much greater than that of fresh virus, and its virulence in different cultures is not invariably associated with mobility of the bacteria; since, although the bacteria remain active, a solution to which eucalyptus has been added, becomes perfectly inoffensive. Putrefaction and cold are without effect on the microbes. On the other hand, a temperature of 80°, maintained for two hours, or of 100° for twenty minutes, destroys all signs of activity. The difference between dried and fresh virus is well seen in their behavior to different so-called antiseptics. Thus dried virus at 32°, even when containing spores, is uninfluenced by such liquids as camphorated or carbolated alcohol, oxygenated water, quicklime, borate of sodium, gaseous sulphurous acid, and the vapor of chloroform, The most active agents are corrosive sublimate, nitrate of silver, and carbolic acid; these destroy both fresh and dried virus, as is also the case with permanganate of potassium, chloral, and eucalyptus.—*Le Progrès Méd.*, February 24, 1883.

A Rapid Treatment of Erysipelas.—Mr. Richard Barwell reports five cases of erysipelas which he thinks are sufficient to show that a very great effect is produced upon erysipelas and its congeners by covering the surface with white lead paint. This effect is, he believes, entirely due to exclusion of air; the lead of that compound is in an insoluble condition; nor does he believe that the inflamed skin is in a state to absorb any material applied on its surface; by the time that it has recovered the lead is separated from the living tissue by a tolerably thick layer of desquamated and dead epidermis. Moreover, lead as a solution of the acetate has been applied from a very early period, and, as far as he knows, without any appreciable benefit to erysipelas.—*Lancet*, March 10, 1883.

The Nature of Soft Chancres.—Dr. Moritz Winter believes that the so-called soft chancre originates from a modification of the syphilitic virus, but is then a separate disease, and can never serve as a source of pure syphilitic contagion. — *Medicinisch-Chirurg. Centralb.*, February 16, 1883.

Extra-peritoneal Nephrectomy.—Brichetti, as the result of his studies and experiments, arrived at the following conclusions (*Gazz. degli Ospitali*, Sept. 3, 1882). 1. The system does not suffer from the sudden removal of one of the kidneys. 2. Nephrectomy (in dogs) has no great danger as an operative proceeding. 3. It is better to abandon the pedicle, previously applying two distinct ligatures with catgut, then to close the wound with the twisted suture, using long and strong pins. 4. The urine undergoes no alteration, chemically or microscopically. 5. Hypertrophy of the heart, which is especially found in atrophy of one kidney (Traube) is never met with. 6. The remaining kidney does not increase in weight or volume, but undergoes a fatty degeneration of the canaliculi, with slight enlargement of the epithelium, noticeable three months after the operation, more evident after six months, and reaching the maximum after the twelfth month. Professors Tizoni and Pieuriti found in rabbits after nephrectomy an increase in weight and volume of the remaining kidney, and a reproduction of glomeruli and tubuli. This the author has not been able to confirm, though he thinks there might be an increase of glomeruli.—*London Medical Record*, March 15, 1883.

Spontaneous Rupture of the Gall-bladder.—Sahlin (*Hygiea*, 1882) relates the following case: Patient thirty-two years of age; mother of four children; has for years had a chronic catarrh of stomach, and complained of pain in right hypochondrium from time to time; she has never had biliary colic. One night, when six months advanced in pregnancy, she was seized with a sudden and violent pain in the abdomen. During the following days the abdomen enlarged and there was extreme tenderness in the right iliac fossa. On the twelfth day miscarriage occurred, and three days later she died without any appearance of jaundice. At the autopsy a large amount of bile was found in the peritoneal cavity; the gall-bladder contained five large calculi, and had ruptured through the anterior wall.—*Weekly Med. Rev.*, March 10, 1883.

On a Direct Communication between the Portal Vein and the Inferior Vena Cava.—M. Ch. Labourin claims to have detected in man a direct communication, other than the capillaries, between the vena cava inferior and the portal vein.

The Treatment of Epilepsy.—Dr. Paul Bricon (*Thèse de Paris*, 1882) has made a series of experiments at Bicêtre regarding the effect of certain therapeutic measures in the treatment of epilepsy. These measures were hydrotherapy, arsenic compounds, magnetism, and pilocarpine.

Among fifty-four epileptic patients to whom hydrotherapy was applied, ten were decidedly improved, seventeen slightly improved, the rest were not affected. Among seventeen of those improved, there was no other treatment.

The bromide of arsenic was used in ten centigramme doses, but with very poor result. Ten patients were treated with it, and only one was improved by it alone.

Daily applications of very large magnets were made upon sixteen patients. The applications were continued for from three to six months. No physiological or therapeutical effects were produced.

The nitrate and hydrochlorate of pilocarpine were tried, in .005 to .05 doses, upon fourteen patients. Seven were improved. Dr. Bricon thinks that only hydrotherapy and the salts of pilocarpine gave sufficiently good results to justify further trial.—*Journal of Nervous and Mental Disease*, January, 1883.

The Prevention of Laceration of the Female Perineum.—Mr. Alexander Duke makes use of the following procedure to prevent rupture of the perineum in labor. When he finds the head fairly engaged in the pelvis, and advancing with each pain, he takes his seat by the patient's bedside, and having lubricated his left thumb, or the first two fingers of his right hand, he introduces either into the vagina, and at the onset of a pain, draws back the perineum firmly, but gently, towards the coccyx, relaxing the tension gradually as the pain lessens till the next ensues, and so on till he can draw back the perineum with very slight effort. He thus tires out the muscular structure, and produces sufficient relaxation for the head to pass.

In most cases so treated there is no danger to the

perineum, but when the pubic arch is narrow (which can be easily determined) he takes the additional precaution of raising the patient's left hip, and supporting it on a hard pillow, while the shoulders are kept low, fomenting the parts, using inunction of lard or vaselin, and taking particular care to direct the head forward by pressure, with his left hand below the coccyx, or a finger in the rectum, leaving the perineum untouched. It has always seemed anomalous to him that the perineum should be expected to dilate on such short notice, namely, "the process of extension," while dilatation of the os and cervix occupy such a considerable time, even with the additional help of nature's hydrostatic dilator, viz., the bag of waters.

The drawing back of the perineum produces no additional pain to the patient, as it is done during a uterine contraction; and he feels sure that, if nurses and students were educated as to the proper way of preparing the perineum previously to its distention with the presenting part, we should see and hear less of lacerated perineum.—*Brit. Medical Journal*, March 10, 1883.

THE EMPLOYMENT OF CHLOROFORM-WATER IN GASTRIC IRRITATION.—It is well known that washing out the stomach with alcoholic liquid is not without advantage in certain chronic affections of that organ, such as cancer, catarrh, and dilatation. DR. BIANCHI (*Lo Sperimentale*, November, 1882) employs chloroform-water in such cases with a view of preventing fermentation. In three cases, of cancer of the stomach, chronic catarrh with dilatation, and chronic gastritis, he introduced daily into the stomach a litre of chloroform-water and allowed it to remain for a minute or two. Instead of irritating still further the mucous membrane, as might be expected, the chloroform-water stimulated the secretion of gastric juice, and was without any toxic properties.—*Gaz. Hebdomadaire*, March 2, 1883.

THE TREATMENT OF SYPHILIS, BY INDIANS.—DR. J. MARION SIMS gives the following as the ingredients of a decoction used with great success by the Creek Indians in treating syphilis:

"Fluid extract of *Smilax sarsaparilla*, fluid extract of *Stillingia sylvatica* (queen's delight), fluid extract of *Lappa minor* (burdock), fluid extract of *Phytolacca decandra* (poke root), āā ʒij; tincture of *Xanthoxylum carolinianum* (prickly ash), ʒj. Take a teaspoonful in water three times a day before meals, and gradually increase to tablespoonful doses.

"In making the fluid extracts, there is some risk of getting a remedy less efficient than the original Indian decoction, because the manufacturer may use roots that have been kept too long, and lost some of their active principles, while the decoction used on the plantations was always made of fresh roots just gathered from the woods. In making the fluid extracts, we should therefore be careful to have them made from roots recently gathered."—*British Medical Journal*, March 10, 1883.

HYSTERO-EPILEPSY IN MAN.—M. PARISOT has under treatm ent in the Hospital Saint-Charles, at Nancy, a young man, eighteen years of age, who is subject to convulsive crises ten times daily, each lasting about one hour. When the attack commences it is announced by pains in the neck and epigastrium, followed by falling and loss of consciousness. The first period is characterized by distortion of the face, convulsive movement of the eyes, and then general convulsions; passionate attitudes terminate the attack, during which there is no incontinence of urine, and the tongue is not bitten. M. Parisot discards the hypotheses of abscess of the brain, epilepsy, or tetanus, as explanations of the convulsions, and thinks that the condition most resembles what is termed hystero-epilepsy in the female. —*Journ. de Méd. de Paris*, February 24, 1883.

SUCCESSFUL GASTROSTOMY FOR COMPLETE STRICTURE OF THE ŒSOPHAGUS.—DR. A. VENER describes in detail (*Mediz. Obozr.*, March, 1882) the case of a man, aged 49, who was suffering from a cancerous obstruction of the œsophagus, the first symptoms of which had been observed about eighteen months before the operation. The patient was extremely emaciated, weighed 105 pounds, was not able to swallow solids, nor, of late, even fluids. The stricture was situated at the distance of 30 centimetres from the incisors. Gastrostomy, to which the sufferer readily consented, was performed by Dr. Knie, after the plan of Fenger and Howse, under the strictest antiseptic precautions (but without spray). The patient bore the operation excellently. The highest temperature (100.6°) was observed on the second day, after the first stage of the gastrostomy. On the seventh day the salicylic dressing was removed, and on the eighth the stomach was opened and a drainage-tube (provided with an Escher's obturator) introduced. On the nineteenth day the patient got up, and on the fortieth left the hospital, feeling quite comfortable and having considerably gained in weight. Drs. Vener and Knie emphatically insist on the necessity of performing gastrostomy in cases of cancerous stricture at as early a period as possible, before the patient's strength has been exhausted and the œsophagus has become absolutely impassable. [This is only the second successful case of establishing a gastric fistula known in the Russian literature. In the first (non-cancerous) the operation was performed by Dr. A. S. Satzenko, of Kieff. All the other Russian cases of gastrostomy (Professor Sklifosovsky's two, Drs. Snegireff, Anders, G. F. Tiling, Stukovenkoff, Kitaevsky) were followed by death within a few days after the operation. The longest survival (nineteen days) presents the second case of Professor Sklifosovsky (*Vratch*, 1880, No. 21, pp. 341–2). Save Dr. Anders' case, in which fatal peritonitis developed (*Peters. Med. Wochensch.*, 1881, No. 21), all the patients died from exhaustion.]—*London Medical Record*, March 15, 1883.

SYPHILITIC DISEASE OF THE RETINAL ARTERIES.—HIRSCHBERG (*Centralb. f. prakt. Augenheilk.*, Nov. 1882) reports the case of a man, aged 39, who had two years earlier suffered from a venereal sore and an inguinal bubo, presented the following symptoms and appearances in his left eye: $V=\frac{15'}{XXX}$; field normal; slight haze of the disk, and enlargement of the veins; an opacity in the vitreous about one millimetre in front of the papilla, like a delicate veil with a dozen reddish-brown dots scattered over it. Besides this, denser membranous opacities in the vitreous and a small hemorrhage over a cilio-retinal vessel, which took the place of the arteria temporalis inferior. Some three weeks later there were observable, in addition to opacities in the vitreous, well-marked white peri-vascular streaks surrounding the arteria nasalis inferior, from which delicate white lines passed perpendicularly into the retina on either side. More peripherally the affected artery plunged into a system of bluish spots, chiefly lying in the retina, but partly projecting into the vitreous, and it terminated in a branched arrangement of red lines covered with retinal hemorrhages. After treatment—mercurial inunction, etc.—the blood became absorbed, but the other appearances remained unaltered. The importance of this observation is somewhat lessened by the absence of demonstration of the presence of syphilis.—*Ophthal. Rev.*, March, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MARCH 31, 1883.

THE BACILLUS TUBERCULOSIS IN DIAGNOSIS AND PROGNOSIS.

THE latest observations on the tubercle bacillus being based on the acknowledged essential relation between it and tubercular disease, have had for their object the determination of its clinical and diagnostic value.

Thus PFEIFFER, of Wiesbaden (*Berliner klin. Wochenschr.*, January 15, 1883), in the recent study of a series of cases, divided them into four grades of severity, and from a quantity representing four or five drachms of sputum he made daily four preparations from each case, and when these happened to contain no bacilli he made a second set of four. He further indicated the number of bacilli in each preparation as, numerous, sparse, and absent. His results were as follows:

In the first or mildest grade the bacilli were numerous 4 times, sparse 14 times, absent 7 times; in the second, numerous 11 times, sparse 10 times, absent 4 times; in the third, numerous 13 times, sparse 10 times, absent 2 times; in the fourth or most serious grade, numerous 16 times, sparse 6 times, absent 3 times.

From this it will be seen that the number of bacilli in the sputum increased with the severity of the disease. The fourth case died a few days after the termination of the observation; the bacilli in his sputum were always "numerous." Only in one case, the mildest, were bacilli absent for three successive days, none being found in twenty-four consecutive preparations.

DR. FRANZ ZIEHL (*Deutsche Medicinische Wochenschrift*, January 31, 1883) found tubercle bacilli in the sputum of 72 out of 73 cases in which the physical signs of phthisis were present; even in such cases in which the local objective condition is wanting can the diagnosis be sometimes confirmed; in one of this kind the method failed, where there could be no doubt as to the diagnosis, while in a couple of cases this demonstration turned the scale in the diagnosis.

On the other hand, in none of 34 non-tuberculous affections of the respiratory apparatus (including croupous pneumonia, acute bronchitis, chronic bronchitis, with and without emphysema, gangrene of the lungs, and putrid bronchitis), were the bacilli present, although many preparations were made from each case.

While Ziehl considers that, according to his methods of staining, amplification, and illumination, he finds the tubercle bacilli in sputum more frequently than others, he still admits that there may be cases in which this new aid to the diagnosis of tuberculosis may lead to error or fail of its purpose. Thus in cases of true tuberculosis the sputum investigated may be derived from the nasal passages or the mouth, and thus be naturally devoid of bacilli, while it still occasionally happens that there may be cases of undoubted tuberculosis in which the bacilli are absent from the sputum. In one case, for example, a patient in whose sputum even elastic tissue of the lung was found, and who died with the signs of a cavity five months after he came under observation, bacilli were never found; while in incipient phthisis, too, the quantity of expectoration is sometimes so trifling that it is difficult to obtain a true pulmonary sputum.

Ziehl cannot, therefore, on this account agree with Balmer and Fräntzel who say that, in cases of lung disease, where, notwithstanding repeated and careful observations, no tubercle bacilli can be demonstrated in the expectorations, tuberculosis cannot exist; nor in their assertion that in all cases of rapid phthisis the bacilli are abundant in the expectoration. Lichtheim and d'Espine confirm Ziehl in this respect.

On the other hand, we dare not infer from the presence of tubercle bacilli in sputum that tuberculosis necessarily exists. Since we must admit the curability of phthisis in rare instances, we must admit the possibility of elimination of the tubercle bacillus. Hence, it is not impossible that tubercle bacilli may enter the respiratory passages by inhalation and be removed by expectoration. And, although, no instances of this kind have as yet been noted, it does not do to admit the second proposition of Balmer and Fräntzel, that where tubercle bacilli are present in sputum, we must have to do with tuberculosis of the lungs. Contrary, also, to Balmer and Fräntzel, as well as Pfeiffer, we dare

not attribute to the number or stage of development of bacilli any weight in prognosis beyond that the bacilli are very often, though not always, abundant where cavities are present. So, too, the bacilli in the bronchi and cavities of phthisical patients can have nothing to do with tubercular processes in other parts of the body.

DR. THEODORE WILLIAMS, of London (*The Lancet*, February 24th), examined the sputum in 130 cases of lung disease. Out of 109 phthisical cases he detected the bacilli in 106, and in 21 cases other than phthisical, he did not find the bacillus in one. DR. HERON found the bacillus in 54 cases, in some of which the *physical signs were so slight that he would have hesitated to make the diagnosis without the aid of the bacillus.*

If such observations as these are correct, and there is a remarkable unanimity in the results, the bacillus tuberculosis is no longer a pathological curiosity, but it behooves every practitioner to examine the sputum from cases of lung disease which are of any duration. How many of us have been consulted in cases in which, without any suspicion whatever that the sickness was to be of more than a few days' duration, and have seen it drift into phthisis, or have, perhaps, been informed by a sudden copious hemorrhage that we have something more to deal with than a simple bronchitis.

THE BACILLUS TUBERCULOSIS AND THE ELASTIC TISSUE OF THE LUNG IN THE DIAGNOSIS OF TUBERCULOSIS.

IT has long been known that one of the most positive aids in the diagnosis of phthisis is the elastic tissue of the lung as found in the sputum by aid of the microscope. In this manner fragments of considerable size derived from the disintegrated air vesicles are discovered with comparative ease—very much more easily and requiring much less manipulative skill than the bacillus tuberculosis as ordinarily sought for. Notwithstanding this fact, it is comparatively rare that sputum is studied, even by hospital physicians, with a view to finding it. It will be a matter of surprise, therefore, to some of our readers to learn that it is found in almost as large a proportion of instances as the bacillus, and is therefore practically as useful in the diagnosis of chronic phthisis. Drs. Dettweiler and Meissen (*Berliner klin. Wochensch.*, Feb. 12) investigated eighty-seven cases of chronic phthisis in different stages. In eighty-five of these clinically diagnosticated cases, or 97.7 per cent., bacilli in larger or smaller numbers were found in the sputum, while in eighty-two, or 93.8 per cent., elastic tissue of the lung was found.

In this connection it is interesting to know that Dr. Formad, of Philadelphia, has discovered that Fenwick's process of preparing sputum for examination for elastic tissue (boiling with liquor potassæ, setting aside to cool, and examining the sediment) serves also to prepare it for examination for bacilli, and in this manner both objects may be sought at the same time, and by a single manipulation.

MEDICAL PHILOLOGY.

THE state of medical terminology and pronunciation is, to say the least, most unfortunate. As in the days when there was no king in Israel, when every man did that which was right in his own eyes, so is it now. The student who has received a classical education has a sufficiently hard time of it, but woe be to him to whom Latin is a novelty and Greek an enigma. The English method of pronouncing Latin, which gives us "vagina" with its long *i* as in light, is followed by not a few, and even adherents of the Continental method (save the late dear old Charles D. Meigs) hardly dare to pronounce it with the *ee* sound. "Major" is almost always sounded with the *a* as in hate, even when combined with "pectoralis" with its *a* as in far, thus commingling the two systems. And now, still further to confuse us, comes the Roman method, with its hard *c*, and its "hydrocephalus" in medicine, and its "keramic" in art.

Still worse, quantity seems to be often wholly forgotten. The followers of all three systems shorten the penultimate of "umbilicus" instead of making it long, and tranform "parĕsis" into "parēsis," and "tinnītus" into "tinnĭtus." Not without reason, then, does Virchow enter a protest, in a late number of his *Archiv*, against the "Barbarisms of Medical Language."

As systems of pronunciation are blended, it is no wonder that even the two ancient tongues themselves are joined in unseemly wedlock. We know one of our best medical authors who has repeatedly written "subdermal," which is no less a monster of language than "hyperextension" and its similars, to which our Berlin linguist objects. Celsus and other Roman authors, though they adopted many Greek terminations from their Grecian masters in our science, and thus unfortunately led the way to such anomalies, always printed the Greek terminations with Greek letters to denote their foreign origin.

Not only have genders suffered strange transformations, but the very forms of words have undergone extraordinary changes. The old Greek "kynanche" and its later "synanche," through the Latin and Italian, became "squinantia," and in English quinsy, as in German Propst (English provost) is derived from præpositus and Pferd from paraverēdus. This same tendency to abbreviation is giving us "ary-" instead of "aryteno-epiglottidean," and other equally bad, though handy, terms.

Nearly every page of our medical journals presents us with the illegitimate "diagnose" for "diagnosticate," and in adjectives a similar forgetfulness of the proper root form is giving us many unjustifiable terms. "Hypodermic" is almost an established word, although the proper form is "hypodermatic;" and "tabetic" is derived from an impossible "tabeticus," in spite of the fact that the genitive of tabes is tabis, and its adjective "tabidus."

So, too, the Greek termination "ides" is made to assume a Latin form, "ideus," and its corresponding feminine as in "mastoideus," both in describing the process which is, and its muscle which is not, "teat-like;" or in "arachnoidea," to denote the membrane which is, and its vessels which are not, "like a spider's web."

An international science like medicine, deriving most of its technical terms chiefly from two ancient languages, and adding to them by the coinage of new terms by authors who write in all the modern tongues, and who are often sadly deficient in classical culture, is necessarily at the mercy of ignorance and carelessness. We bespeak, therefore, from our teachers, and especially our educated authors, more care and exactness in the use of language. He who mispronounces a word is guilty of philological murder, and he who joins Latin and Greek is the author of a linguistic miscegenation.

We trust eventually to see a science of literary orthopædy arise in medicine, the province of which shall be to correct the deformities of speech, deformities which are as obnoxious to the ear of the scholar as is a clubfoot or a knock-knee to the eye of the surgeon.

CHEMICAL TREATMENT OF SEWAGE—THE PETRI SYSTEM.

For over two years this system has been in use experimentally at the Plotzensee prison near Berlin, which aggregates a population of about two thousand persons. Filtration through turf, gravel, and sand, with precipitation by lime, sedimentation, and subsequent filtration, form the steps of the new process. The turf acts, of course, mechanically, but it is claimed that it also exercises a chemical action, causing the destruction of dissolved organic matters, the retention of ammonia, and the preservation, by an antiseptic property, of substances prone to decomposition which may have been retained by it. The sand and gravel are simply filtering agents. The lime precipitates much of the organic matter, such as the acids which take their origin in the fermentation of the sewage, and especially combines with the carbonic acid present, carrying down in a sedimenting basin during its precipitation all the mechanically suspended matters of the sewage. The turf is understood to last a long time without deteriorating in its chemical qualities, or choking in its pores.

The city government of Berlin has recently instituted an investigation into the working of this system with the view of applying it to the general sewage outlets of the city. The sewage has been examined by chemical means before and after its purification—and the effluent liquor has been compared with certain river and well waters, and with the effluents of certain farms where sewage irrigation is carried on, the results being understood to be extremely favorable to the new process.

The purified sewage is considered qualified for admission into any water-course in the country, provided the process is carried on under judicious and watchful supervision. In addition to the chemical proof of the quality of the purified sewage liquid, it was shown capable of sustaining vegetable and animal life notwithstanding the chemical treatment, by lime, which it had undergone. Certain chlorophyleaceous algæ flourished in it and fishes thrived. The value of the sludge as a manure is also adverted to, as is usual in the history of a new chemical process for the purification of sewage, the said sludge containing so much nitrogen and so much phosphorus.

But so many chemical methods have been introduced, with reports showing their ability to deal satisfactorily with the two difficult questions, the disposition of sewage and the pollution of rivers, and have failed when applied on the large scale, that we must hesitate before accepting the Petri process as presented by their chemist to the city authorities of Berlin.

SYSTEMATIC POST-MORTEMS.

It is a matter of no little surprise, when we once have our attention directed to the subject, that so many valuable, and in many cases indispensable, data are entirely omitted from even the best of our reports of autopsies. Who of us give the weight and volume of the various viscera, the length of the large or the small intestine, or the circumference of the principal arteries?

Following the lead of the anthropologists, and especially in this country of Dr. Bowditch and the Massachusetts Medico-Legal Society, the Surgeon-General, U. S. A., has issued a circular of instructions, directing that these facts and figures shall be included in army reports of autopsies, besides the ordinary facts of the medical histories. It is a step in the right direction, *i. e.*, the substitution of precision for a guess; and when a sufficient number of facts are gathered, we can establish a norm as to all these organs. Sufficiently detailed instructions are given as to the precautions to be adopted and the methods of making the observations.

The government services are so favorable to all such exact scientific observations, that we should be very glad if the Medical Corps of the Navy and that of the Marine-Hospital Service would adopt a similar form. True, so full a record requires time and trouble, but what is worth having that does not?

DIVORCE.

IN the *North American Review* for April, 1883, Judge Jameson closes an article full of startling disclosures, with some excellent suggestions. The increase in the number of divorces in this country, and especially in New England, is one of the most serious of the social problems affecting the population. In Massachusetts, in 1878, there was one divorce to every 21.4 marriages; in Vermont, one to 14; in the Western reserve, one to 11.8; and in one of its counties, one to 7.4.

Judge Jameson points out that the law, thus far, has only considered the interests of the husband and the wife, and has neglected to make any provision for the representation of the other two and very deeply interested parties, viz., the children and the State. He proposes that a guardian *ad litem* be appointed for the children, who should be heard in their interest, and be paid by the complainant; and that the State should be represented by its attorney. In addition, he advocates a Federal statute on the whole subject of marriage and divorce to make it uniform all over the country. Coming from one who is evidently of very "liberal" views on the subject, these opinions carry all the more weight, and should receive earnest consideration.

THE NEW YORK COUNTY MEDICAL SOCIETY AND THE NEW CODE.

A LARGE and spirited meeting of the Medical Society of the County of New York was held last Tuesday evening, to elect three delegates to the State Medical Society, to fill the vacancies created by the resignations of Drs. Webster, Johnson, and Foster, who had been elected permanent members. The meeting was crowded with members who were present to give expression, through the election, to their views on the New Code.

Dr. Austin Flint, Jr., nominated Drs. Charles Hitchcock, C. S. Ward, and C. A. Leale, to fill the vacancies created by the resignations; and stated that these gentlemen were earnest advocates of the Old Code, and in the State Society would vote for its restoration. Dr. D. B. St. John Roosa nominated Drs. Walter R. Gillette, P. Albert Morrow, and F. M. Weld, who were announced to be supporters of the New Code. The ballot resulted in 94 votes for the Old Code ticket, nominated by Dr. Austin Flint, Jr., against 71 for the New Code supporters, nominated by Dr. D. B. St. John Roosa.

This important action in the home of the New Code is significant, and indicates that the profession is aroused to the importance of the issues involved. By the election of these three gentlemen, the delegation of the New York County Society no longer remains solid, and we trust that the influence of an aroused professional sentiment may make itself felt still further in this matter.

MYOSURIC URINE.

UNDER the above title M. Denancey describes a kind of urine which must have attracted the attention of those of our readers accustomed to make urinary examinations.

The following are the physical characteristics of such urine: It has a strongly reddish-yellow color; has a specific gravity which oscillates between 1025 and 1029; does not contain any sugar; is but slightly acid; blackens silver vessels in which it is boiled, and is colored brownish by the cupro-potassic test. He finds, further, that it has the property of decolorizing iodide of starch, which is due to the unoxidized sulphur in the large quantity of extractive contained in it. M. Denancey thinks that this condition of the urine is a pathological state related to diabetes, and he therefore proposes to name it *myosuric diabetes*.

PART III. of the surgical volume of the *Medical and Surgical History of the War of the Rebellion* has just been issued from the Surgeon-General's Office. It is a portly volume of one thousand quarto pages, and completes the surgical portion of the history. The work on this volume, which was interrupted by the untimely death of the late Surgeon George A. Otis, has been ably carried on to completion by Surgeon D. L. Huntington, and it covers the following subjects: The treatment of regional injuries of gunshot origin, and those of the lower extremities; miscellaneous injuries, not strictly gunshot in character, but incident to the military status; wounds and complications, including the nature, peculiarities, and effects of missiles and projectiles, and conditions affecting the course and result of wounds, with especial reference to the graver complications of secondary hemorrhage, erysipelas, pyæmia, gangrene, and tetanus; anæsthetics, and a brief historical sketch of the medical staff, and a description of the materia chirurgica, and of the methods of field, railway, and water transportation of the wounded. The volume is profusely illustrated, and sustains the high reputation which is enjoyed by its predecessors of the series. Of the work in detail, we shall have more to say hereafter.

Our readers will learn with deep regret of the death of Dr. William H. Van Buren, which sad event occurred last Sunday morning. Dr. Van Buren was an eminent surgeon, and a distinguished citizen, and his death is a profound loss to the profession of which he was a most esteemed member. Of his life and labors, a brief sketch will be found in another column.

REVIEWS.

Color-blindness: its Dangers and its Detection. By B. Joy Jeffries, A.M., M.D., Ophthalmic Surgeon to the Massachusetts Charitable Eye and Ear Infirmary, Carney Hospital and New England Hospital for Women and Children, etc. etc. Revised and enlarged edition. 12mo. pp. 334. Boston: Houghton, Mifflin & Co., 1883.

This work was first published in 1880, and the demand now for a second edition shows that it has been well received. It has an established position as a standard text-book on the subject of which it treats; in fact, it is the only one in the English language, and its possession is therefore a necessity to all who wish to be up to the times in this branch of ophthalmic surgery.

The new matter in the present edition comprises the statistics of recent examinations for color-blindness, both in this country and abroad, the law passed by the Massachusetts Legislature in 1881, for the examination of railroad employés, and that which went into force in Sweden in January of the present year. Also the Congressional bill for the appointment of delegates to the proposed international convention to establish regulations for the control of color-blindness on the sea, which has been twice favorably reported by the Naval Committee, to which it was referred, but has not yet been acted upon by the House.

Eighteen pages have also been added to the already voluminous bibliography. Of the type, paper, etc., it is enough to say that it comes from the Riverside Press, and is equal to that of the first edition.

The Compend of Anatomy. By John B. Roberts, A.M., M.D. Third edition. 12mo. pp. 198. Philadelphia: C. C. Roberts & Co., 1882.

This excellent little compend has reached its third edition in less than as many years. Within its sphere, it is one of the most useful books of its class, and each edition has witnessed some slight improvement. We could, however, wish for a few more definite articles, especially in the table of contents, even though the process of compression had necessitated a rather abrupt style.

SOCIETY PROCEEDINGS.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Stated Meeting, March 7, 1883.

Edward Harsthorne, M.D., in the Chair.

Dr. George Hamilton read a paper entitled

SEWER GAS, AND ITS ALLEGED CAUSATION OF TYPHOID FEVER,

in which he said that, in his country practice, he had nearly always found that the young men who were at work in the fields were more frequently attacked with typhoid fever than the females, who were generally engaged in domestic duties in or about the house; and if, as the sanitarians declare, "there is in the country houses, or the surroundings, something equivalent to sewer gas," why is it that the reverse, as to sex, should not be the case? Diphtheria is also said to be caused in great measure by sewer gas; why is it, then, that the most violent and fatal attacks of this malady occur in the country, sweeping off at times four, five, or six children, in a single family, without a thought of sewer gas; whilst in cities, with sewer gas almost everywhere, the proportionate mortality is much less. Notwithstanding the testimony of Dr. Alfred Carpenter, of London, to show the causation of scarlatina by this agent, here again such testimony is confronted by facts similar to those adduced in regard to diphtheria. It is only a few months since scarlet fever appeared in a town in Pennsylvania, noted for its cleanliness, and occasioned a proportionate degree of mortality unknown in Philadelphia.

It is now time to confront the popular opinion, he contended, that typhoid fever, diphtheria, and scarlet fever are caused by sewer gas, and that to a degree unequalled by all other alleged causes combined. In attempting to do this, such cases as the following will be completely ignored. Mr. A., on returning from his summer tour, perceived, distinctly, the smell of sewer gas in his house, and fell sick on the third day with typhoid fever. What can be said against sewer gas in this case, it may be asked. In answer, it may be said that while, by a bare possibility, the gas was the cause of the disease, the probabilities are all the other way. In the first place, the period of incubation is from eight to twelve days; in the second place, his experience has convinced him that in not more than one house out of five has any smell or sign of sewer gas been detected, either before or during an attack of typhoid fever. And again, if the opinion lately advanced by a few of the most eminent authorities that, as at present constructed and placed within the dwelling, the apparatus is incapable of excluding the gas, is correct, then, in such a city as Philadelphia or New York, many thousands more must be added to the tens of thousands of houses said long ago by the alarmists to be infected with sewer gas. In this connection, it may further be stated, that if the dwellings of this city and those of New York are infected to the extent asserted, then the conclusion is inevitable that the mortality would be absolutely frightful, and yet, in some weeks, in our city and in New York, with, taken together, about three millions of people, the deaths have been down to two, three, or four; while diphtheria caused, as sanitarians and experienced physicians say, by the same sewer gas, has at this identical time occasioned weekly, the death of about thirty or forty persons. In the third place, it is well known that many individuals on returning from the country to their homes in the city, in a very few days, before the period of incubation has expired, have had attacks of typhoid fever, and such cases may fairly be regarded as having had their origin in the country.

An important point in the history of typhoid fever, as it occurred in the country, was, that if the disease once appeared in a farm-house, it would, as a rule, attack more than one of the members of the family before leaving it, and this, too, when the physician knew of no other case within a mile or more of the afflicted family. Now this is in entire accord with the admitted contagiousness, under certain conditions, of typhoid fever. The feature just noticed does not, as a rule, occur in the city, for in an immense majority of cases there will be but one member of a family attacked. Now it has been said by a somewhat noted medical statistician, and concurred in by many others, that if a

case of typhoid fever appears in a family, it proves the existence of gas or filth in immediate relation with the residence. This is certainly explicit; but the question is, how happens it that, with such an efficient cause for the first case, it is only occasionally followed by others in the family? But, again, it may be asked, if sewer gas, for this, after all, appears to be the great "*cheval de battaille*," has not been, and is not yet excluded, by even the best plumbing, from the finest houses in this city or in New York, and, consequently, that tens of thousands of houses in both cities are in this fearfully exposed condition, how comes it that in Philadelphia, with 900,000 inhabitants, the Board of Health has recently reported but two deaths from typhoid fever in one week, and four in another; whilst diphtheria, said to be due to the same agencies, has prevailed at the same time to an alarming extent? The returns of the Board of Health of New York present similar statistics, showing comparatively fewer deaths from typhoid fever than Philadelphia, but a larger proportionate fatality from diphtheria and scarlet fever. That many physicians neglect to carefully examine these reports is well known, and yet they are the only available and reliable sources of information in regard to the character and movement of disease. If, instead of this reprehensible neglect, a diligent and discriminating examination were regularly made, it would do much to prevent misconception and error in regard to the actual causation of disease, a subject admitted by the most experienced and gifted minds to be one of equal difficulty and importance.

In this connection it must be stated that the reports of the Board of Health of Philadelphia show, unmistakably, that in the central portions of the city, where sewers and water-closets are most numerous, there is, as a rule, less typhoid fever and diphtheria than upon the outskirts, adjacent to the country; and this was the fact in regard to bilious remittent fever, before it gave place to typhoid. Neither is it matter of surprise, for, just in proportion as the streets have been extended into the suburbs, graded and paved, houses erected thereon, and sewers constructed to carry off the surface drainage, a diminution of fever, whether intermittent, remittent, or typhoid, has been the beneficial result of such improvements.

COL. WARING, who was present by invitation, was called upon by the Chair to discuss the subject considered in the paper.

He remarked that he desired to say one word for sanitary engineers with regard to the cause of typhoid fever, and this was, that they had long since abandoned the opinion that sewer gas was the cause of the disease. He thought it very important that filth should be gotten out of the way so as not to become a source of contamination to the water-supply. The literature of the subject seems to prove that typhoid fever in the country is due to drinking water which has become contaminated. Cleanliness is safe and important, and efforts should be always made to secure it.

DR. HAMILTON said the quality of the drinking water remained essentially the same from year to year, whether typhoid fever prevailed extensively, or was absent. So, also, in regard to vegetables and roots for family use. These are laid up every season, generally in trenches, covered with clean straw and earthed over. On consulting several German monographs Dr. H. had found the experience of the writers to conform with his own, that males suffered more from typhoid fever than females, and that from the fifteenth to the twenty-first year, the period of rapid growth, the danger, in case of an attack, was augmented.

DR. J. M. KEATING said that the paper just read might mislead some into the supposition that *sewer gas* was considered a cause of typhoid fever. It may be well for us at once to dispel such an idea, and to couple with the paper just heard the emphatic endorsement of this body that *sewer gas*, as far as *typhoid fever* is concerned, is simply a VEHICLE by which the specific germ may enter the system of one prepared to nourish and develop it. There is no need to debate the question as to the greater importance of infected drinking water; the incidents in the paper just heard, the greater prevalence of the disease in the rural districts where privy wells contaminate the drinking water, and the remarkable statistics of the New England country towns where the wells for sewerage and drinking purposes are under one roof, the fact that these localized epidemics are usually traceable to one primary case entering the village, are all sufficient evidence in themselves.

But though *sewer gas* may not always carry the germs of typhoid fever, it has a poison of its own equally terrible in its consequences.

The modern improvements in house-drainage are unfortunately too often the means of carrying the most deadly vapors directly into the abodes of luxury and wealth. At those hours when depressing influences have disarmed their victim, these noxious gases steal insidiously into his chamber, and do such violence as to render fatal by the most serious complications such diseases as are otherwise mild and harmless in themselves. Whether the concentrated miasms from paludial emanations or the outpouring gases from a sewer through *siphoned* traps, the unconscious sleeper breathes poisons as potent in their devitalizing effects as if he inhaled the germs of typhoid fever in their purity or drank water impregnated with the excreta of typhoid cases. *Sewer gas* is not necessarily a *cause* of typhoid fever, except when it carries its germ, but it is the most potent cause of the "typhoid state;" and there is a decided choice between these two evils—in favor of the former.

Early manhood carries with it a decided predisposition to typhoid fever.

The typhoid germ is certainly more deadly if its vehicle be poisonous also; and it becomes our duty to add an earnest appeal to that which seeks by proper legislation to give us pure air for our children to breathe, and pure uncontaminated water to drink.

DR. J. G. RICHARDSON remarked that Dr. H.'s illustrative cases may be very plausibly explained in accordance with the modern views respecting the danger to human health from impure drinking water, foul sewer air, and other grave sanitary errors.

Dr. Hamilton mentioned the case of the mother of a family who contracted typhoid fever away from home, and brought it back to her farm house, where several members of the family seemed to take the disease from her, and argued that this circumstance proved that the infection of typhoid fever was not carried by sewer gas, because in this instance no sewers existed near the place. The true explanation of this seeming anomaly is, he believes, however, that, whilst typhoid fever is sometimes carried by sewer gas, it is more frequently conveyed in drinking water contaminated by sewage, and that in this case the diarrhœal discharges of the mother were emptied near enough to the family well to soak through the ground into it, and, by polluting the drinking fluid, transmit the disease to other members of the household.

That some such mode of propagation may have existed is shown by a remarkable fact related by Prof. Flint, upon whom Dr. Hamilton relies as an authority against the dangers of sewer gas, which is briefly as follows: A young man travelling by stage-coach in Vermont was taken sick, and left at a wayside inn in a small village. His complaint soon proved to be typhoid fever, and in a short time the disease appeared

in each of the neighboring houses, the inhabitants of which used water from the tavern-keeper's well, *except one*, whose residents had quarrelled with the landlord, and consequently went elsewhere for their water-supply.

In the light of recent sanitary science, then, it appears that many people, many whole families, in rural districts, suffer from typhoid fever because they drink well water polluted by direct mixture with fecal matter containing the specific fever germ, which soaks through the soil, often directly into the well; whilst in cities a few persons, relatively, are attacked with typhoid fever, and many with diphtheria, etc., by inhaling poisoned sewer air from stationary washstands and other modern conveniences. There are probably one hundred thousand village and farm houses in the United States today where the cesspools *feed* the wells in this abominable manner, and such wells surely in their turn *feed* from time to time the churchyards in their neighborhood.

Again, Dr. Hamilton inquired, why is it, if sewer gas is the cause of both typhoid fever and diphtheria, we now have, according to the late reports of the Board of Health, only two or three deaths per week from the former disease, and thirty or forty from the latter? The obvious answer is that sewer gas can only convey the *materies morbi* (the disease germ as I believe it is) with which it is freighted, and, at the present time, sewer air in but few houses is contaminated with typhoid-fever poison, whilst in many it is loaded with diphtheria germs. Precisely as drinking water might contain both lead and copper in varying proportions, and accordingly as one or the other temporarily predominated, would persons who imbibed the fluid be liable to exhibit the symptoms of lead palsy or of copper poisoning.

Although he is not yet prepared to endorse the *dictum* of a late English hygienist, who declares "For every death from typhoid fever, somebody" (meaning some plumber, architect, or sanitary engineer) "ought to be *hung*," he does hope and believe that the time is not far distant when at least the charge of criminal negligence will lie at the door of every physician who, after being warned by the occurrence of one case of typhoid fever, diphtheria, etc., in a dwelling, does not immediately endeavor to guard the other residents of that house against the germs (or poison) of infectious disease, by a diligent search for the sanitary defects in water or milk supply, or in the disposal of sewage, which will almost certainly be discovered.

After having spoken of the germs of typhoid fever, diphtheria, etc., entering sleeping apartments from stationary washstands in spite of traps, he said that in this connection he desired to show, just how, as he conceived, these poisons may penetrate through such mechanical contrivances. He then exhibited the ball of an ordinary Bower trap, covered with a coat of fungous growth, and a portion of the slimy coating from one of the pipes of similar structure. Since these form a continuous lining quite through the trap, it is obvious, he thinks, that it may have crept up from the sewer itself, thus forming on the inner or house side of the trap a new starting-point for the evolution of disease germs, against which of course the most perfect water seal is absolutely no protection. This, he believes, is what really occurs in a multitude of instances, as he pointed out in a paper entitled *Why Sewer Traps are Unreliable* in The Medical News, Sept. 2, 1882. The true remedy for the dangers of sewer gas poisoning is, therefore, as explained in that article, to be found in sterilizing the whole interior of our traps and waste-pipes with slow currents or drippings of powerful disinfectants, such as the salts of iron, zinc, mercury, or arsenic, "just as the shores of the Dead Sea and the banks of certain small streams are sterilized, by mineral ingredients or poisonous metallic substances from manufacturing refuse, with which their waters are mingled."

THE PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, March 8, 1883.

The President, James Tyson, M.D., in the Chair.

Dr. J. T. Eskridge exhibited a

UNIQUE SPECIMEN OF OSSIFICATION AT THE AORTIC ORIFICE,

which was sent him from a distance, and consisted of about one inch of the cardiac end of the thoracic aorta, the aortic semilunar valves, and the immediate portion of the heart. The specimen was removed from a man, aged about seventy, who had suffered a number of years from severe heart-disease. The walls of the large arteries were thickened, rigid, and contained numerous deposits of inorganic matter. The left ventricle was enormously enlarged. He was unable to obtain any information with regard to the condition of the cardiac valves other than those of the aortic orifice.

Description of the specimen—The aorta, where it surrounds the valves, for about half an inch in extent is a hard, unyielding substance of fibrous tissue, and calcified and ossified matter. The valves in several places are about one-fourth of an inch thick, and seem to have been almost entirely transformed into bone-like material. They are rigid and immovable, and have almost completely cut off all communication between the heart and aorta. One of the leaflets, about three-fourths of an inch in all directions with its vegetations, stretches across the aorta, lies against and is apparently adherent to the other segments of the valves, the latter being curled upon themselves. The central portion of the aorta is entirely occluded, and only two small openings through which the blood could have escaped from the left ventricle, are seen between the valvular leaflets near their peripheral attachments. The larger of these holes admits a flattened probe three mm. wide by one thick; the smaller is about two-thirds as large. Three other smaller orifices have existed, but these were obliterated before death by a thin, fibrous, transparent membrane, which is still seen. The valves on the cardiac side are tolerably smooth, but on the aortic side they are very rough, one of the leaflets supporting a vegetation ten mm. long. One of the segments of the valves is adherent to the inner coat of the aorta for about half an inch in extent, the free end of the valve being folded upon itself, and pointing towards the nearly closed aortic orifice. After macerating the specimen in water for forty-eight hours, the diseased valves still remain inflexible.

Drs. Formad, Dunn, Griffith, and Edwards reported having seen similar, or nearly similar cases.

Drs. Tyson and Nancrede called in question the correctness of calling the disease *ossification* of the valves, as it was in reality a *calcification*.

Dr. Shakespeare concurred in this view, and thought that ossification rarely, if ever, occurred in this situation.

Dr. Eskridge said that Hayden (*Diseases of the Heart and Aorta*, vol. ii. p. 839) referred to bony deposits in the aorta and its valves, as follows: Sir Dominic Corrigan exhibited before the Pathological Society of Dublin (see *Proceedings*, vol. ii., new series, February, 1864) the heart of a young woman, in which the root of the aorta had undergone complete osteoid transformation; it was likewise greatly dilated, and the aortic valves had been rendered thereby inadequate. During the patient's last illness, a systolic murmur of metallic quality, appropriately designated a "trumpet-

bruit," was audible at the base, and in the ascending aorta and carotid arteries; there was likewise a soft diastolic murmur. He regards a "trumpet-bruit" as absolutely diagnostic of bony deposit in the aorta, either in the form of a "rim of bone," or a "projection or tongue of bone." In the same paragraph Corrigan refers to Dr. Bank's specimen of "a tongue of bone" projecting into the aortic orifice.

DR. NANCREDE exhibited

A TUMOR COMPOSED OF MILIARY TUBERCLES OF THE SUBCUTANEOUS ADIPOSE TISSUE CONNECTED WITH ONE OF THE ANTERIOR CUTANEOUS BRANCHES OF THE LUMBAR NERVES.

The patient from whom this unique tumor was removed was a young girl, eighteen years of age, who for four years past had had occasional coughs, with at times some bloody expectoration; but was able to attend to her occupation of housework; her family history was not characteristic in any way. About one year since, she thought that she "strained herself," since when she has been subject to severe attacks of abdominal pain, which extends to various portions of her body. She was admitted to the female medical wards of the Episcopal Hospital last fall, when dulness on percussion and harsh respiration at the apex of one of the lungs was detected. During December, 1882, the pains increased, and the right thigh became flexed upon the abdomen. A small, exquisitely sensitive, nodulated tumor was now detected just to the outer side of the right rectus abdominis. Dr. Morris J. Lewis, by whose kindness he was enabled to present this specimen, then asked him to see the case with him. Under ether, he found a nodulated mass, beneath but attached to the skin, and freely movable upon the deeper parts. He then thought that the growth was one of the ordinary so-called neuromata, *i. e.*, usually fibrous growths in connection with some nerve, and that the pains were reflex, as was also the flexion of the thigh. February 20, 1883, he accordingly removed the growth, which to his surprise was markedly infiltrated, and only at one spot in any sense encapsulated, where it evidently had developed around a small cutaneous nerve and artery. The wound did badly and has left an indolent ulcer, but *all the reflex pains, and flexion of the thigh have disappeared;* and, while the lung is breaking down, nevertheless the patient is gaining flesh, and looks and expresses herself as much better, and thoroughly satisfied with the results of the operation. Dr. Nancrede termed this growth "unique," because he believes that none such has been reported, *i. e.*, subcutaneous masses of tubercle large enough to require the surgeon's knife, and liable to be mistaken for other neoplasms. The present growth was about an inch in its various diameters, as far as could be estimated. Microscopically, sections show fibrous and adenoid tissue, with giant-cells, according to the kind report of Prof. Simes, whose observations have been confirmed by Dr. Formad, and other pathologists, as well as by himself.

DR. G. G. DAVIS said that he had seen a somewhat similar case in the clinic of Prof. König, of Göttingen. A young man had a subcutaneous tumor just above and to the outer side of the patella. It was about one inch and a quarter in diameter, and perfectly circumscribed. It and a portion of the joint-capsule, including the part to which it was attached, were excised antiseptically. On the synovial membrane were found a number of what appeared to be miliary tubercles. There were no other evidences of tubercular disease, and he recovered with a good, movable joint. Prof. König regarded the case as one of true localized tuberculosis. He examined the excised portion microscopically. The tumor was hard, but had undergone cheesy degeneration.

DR. NANCREDE thought that this interesting case related by Dr. Davis still left his own unique, as Prof. König's case evidently had its origin from the synovial membrane, which was so closely related to the other serous membranes, which, as is well known, are so very prone to miliary tuberculosis.

CORRESPONDENCE.

SUDDEN DEAFNESS FROM MUMPS.

To the Editor of THE MEDICAL NEWS.

SIR: In the interesting article by Dr. George C. Harlan, on this subject, in the last number of your Journal, he states "it is only recently the clinical histories of a few such cases have been reported." In 1874 I published in *The American Journal of the Medical Sciences*, vol. lxviii. page 377, an article on disease of the internal ear, in which I gave a detailed account of two cases of sudden deafness from mumps, and I also made some remarks on the cause of the affection.

Since this report seems to have been ignored by the recent writers upon this subject, I have compiled all my cases of this kind, including of course those just alluded to. They will appear in the next number of the *Archives of Otology*, soon to be issued.

I am sir, very respectfully, etc.,

D. B. ST. JOHN ROOSA.

NEW YORK, 24th March, 1883.

A TOOTH AT BIRTH.

To the Editor of THE MEDICAL NEWS.

SIR: Yesterday I drew a tooth for an infant seventeen days old. The child was a female, one-quarter Sioux. When it came into the world it had this tooth, a lower central incisor, developed as now presented.

The crown and body of the tooth seemed fully developed, and as large as the usual milk tooth. The attachment to the gum, instead of a root, appeared to be a mere fleshy connection, and hence not very solidly implanted. Moreover, it gave the child great uneasiness in nursing. The tongue in moving over the sharp surface presented by the tooth, in every attempt at drawing milk from the breast, became abraded, and finally ulcerated. As soon as the tooth was extracted, the child took the breast with avidity. The pain caused by nursing had undoubtedly interfered with the child getting a sufficient amount of nourishment.

I thought this case sufficiently unique to justify at least a brief reference to it.

Yours, etc.,

FORDYCE GRINNELL,

PHYSICIAN TO PINE RIDGE AGENCY, DAKOTA.

PERIOD OF STUDY REQUISITE TO ENTER THE ARMY MEDICAL DEPARTMENT.

To the Editor of THE MEDICAL NEWS.

SIR: Dr. Harvey L. Byrd, of the Baltimore Medical College, in his letter published in THE MEDICAL NEWS of March 10th, makes this statement: "It has long been the custom of the United States Army and Navy Medical Examining Boards to pass those *only* who *are* qualified to enter the medical service of our common country, without regard to period of study, or whether they are M.D.'s or not."

Dr. Byrd is evidently misinformed, at least in so far as the army is concerned, and the last clause of his assertion is misleading, and places the Medical Corps

of the Army, and I think of the Navy also, in a false position, which we naturally resent.

The law on the subject is clear, and the custom of the Army Board conforms to this law, namely, An Act of Congress approved June 23, 1874, ... "Candidates [for the Medical Corps of the Army] must be between twenty-one and twenty-eight years of age, and graduates of a medical college, having a thorough and complete course of medical education, evidence of which must be submitted to the Board before examination." Any graduate of a medical college, graduated on *merit*, without regard to period of study, would, I believe, stand a poor chance of passing an Army Medical Board, or even of coming before it for examination, if he should be so rash as to apply for an invitation to do so.

The law requiring that a candidate shall be a graduate of a medical college, is slightly varied by paragraph 2273 of Army Regulations, 1881, which requires the candidates to be "graduates of a regular medical college." This is further modified by General Order No. 65, Current Series, 1882, which directs that a candidate must be "a graduate of a regular medical college, evidence of which, his diploma, must be submitted to the Board."

If any non-graduate ever entered the Medical Corps, United States Army, prior to 1868, I have not heard of it, and I am sure none has since.

Yours very respectfully,
J. C. Worthington,
Captain and Assistant Surgeon, U. S. Army.

Fort Wayne, Detroit, Mich.,
March 26, 1883.

OBITUARY.

William Holme Van Buren, M.D., LL.D. (Yale).

On Sunday morning, March 25th, after an illness that followed a slight stroke of paralysis, and had been prolonged through many months, Dr. Van Buren died.

He was prominent for so many years as a teacher of anatomy and surgery in New York, so widely and so favorably known as a writer, so generally sought in consultation, that the principal features of his life and character are doubtless familiar to most of our readers.

He was born in New York, April 5, 1819. His great-grandfather was a Holland physician, and came to New York in 1700, and practised medicine there until his death; he was succeeded by his son, the grandfather of the subject of this sketch, who practised in the same city until his death in 1812. Dr Van Buren's mother returned to Philadelphia after the death of his father, which took place during his childhood, and there he was educated until he entered Yale College in 1834. He left his class during its junior year, returned to Philadelphia, and studied medicine in the University of Pennsylvania. In 1838, he went to Paris with his preceptor, and studied in that city until the autumn of 1839, occupying the position of *externe* under Velpeau at La Charité, and was graduated at Philadelphia in 1840. It is worthy of remark that the subject of his thesis was the immovable apparatus, the starch dressing, in the treatment of fractures; that even at this early period of his career he appreciated the value of and sought to popularize this method of treatment, which did not win general recognition until after the lapse of more than twenty years. The thesis received the signal honor of publication by the faculty of his school, and young Van Buren, who was just completing his twenty-first year, was invited to lecture upon the subject, and to give a practical demonstration of the method in the amphitheatre, where, the day before, he was sitting as a student.

Two months after graduation he was appointed assistant surgeon in the Army, ranking first in the competitive examination, and entered upon his duties in the following July. After a short service at the station in Buffalo, he went to Florida, on the staff of General Wool, returning in 1842 to marry the eldest daughter of Valentine Mott, whose acquaintance he had made in Paris. After a short stay in Florida he was assigned to duty in Washington, on the staff of General Scott. He resigned from the army in 1845, and took up his abode in New York.

After serving for several years as Prosector to the Chair of Surgery in the University of the City of New York, under Dr. Mott, he was appointed, in 1852, to the Chair of Anatomy in the same school, succeeding Prof. Granville Sharp Pattison, a position which he held until 1866, and combined with it the duties of Professor of Clinical Surgery, with especial reference to diseases of the genito-urinary system.

In 1847 he was appointed Surgeon of Bellevue Hospital, and in 1852 Surgeon of the New York Hospital, and subsequently held a similar position in St. Vincent's Hospital. For several years previous to his appointment as Professor of Anatomy, he gave private instruction to students of medicine, in connection with Dr. Metcalf and two or three other young practitioners.

His life during the first fifteen or twenty years of his practice in New York was extremely laborious. He spared no pains to perfect himself in his profession, to do thoroughly the work that came to him to be done. Success came promptly, and was complete; and it showed itself not only in the extent of his practice, the number of his *clientèle*, but also and especially in the recognition and respect given him by the profession.

At the outbreak of the war, when associations to aid the wounded were forming all over the country, he was chosen to represent the hospital surgeons of New York in a committee composed of representatives from four of these associations, to visit Washington for consultation concerning the needs of the service. Out of this visit grew the Sanitary Commission, in the organization and management of which he took a very prominent part during the five years, as a member of the Executive Committee. It brought him, also, into close relation with the officers of the Government, who showed their appreciation of his ability by offering him the position of Surgeon-General, and, on his declining to accept the offer, by asking him to name a candidate.

His health, which had been much affected by his residence in Florida, failed under the pressure of this work, and in 1863 he contracted typhus fever and was brought almost to the point of death. In 1865 he spent six months in Europe with his family, and on his return purchased a country-place at Shrewsbury, New Jersey, and began to reduce his active practice, spending a portion of each week at this place.

About 1868 he was appointed Professor of the Principles of Surgery at Bellevue Hospital Medical College, a position which he held until his death. In 1862, when only forty-three years old, he resigned from the New York Hospital, his only remaining active surgical position; he was appointed consulting surgeon a year or two afterwards, and in 1876 was elected President of its Medical Board, and delivered the public address in Chickering Hall on the opening of the new hospital building. At the time of his death, and for many years previously, he was a member of the consulting staff of Bellevue, the Woman's, and the Presbyterian Hospitals, and of several dispensaries. He was President of the New York Pathological Society for two terms, and Vice-president of the New York Academy of Medicine. In 1867 he was elected a corresponding member of the *Société de Chirurgie* of Paris, and in

1879 was one of the founders of the New York Surgical Society.

His published works consist of translations of Morel's *Histology*, and Bernard and Huette's *Operative Surgery*, a small volume composed largely of collected papers under the title of *Contributions to Practical Surgery*, 1865; *Lectures upon Diseases of the Rectum*, 1870, and a second greatly enlarged edition of the same in 1881, and a text-book on *Diseases of the Genito-Urinary System with Syphilis*, in collaboration with Dr. E. L. Keyes, in 1874. In addition to these he wrote and published many articles in the medical journals, including a recent valuable contribution to our own columns on the subject of litholapaxy (THE MEDICAL NEWS, January 14, 1882); a paper on "Aneurism," read before the International Medical Congress, in Philadelphia, in 1876, and (his last work) the article on "Inflammation" in the *International Encyclopædia of Surgery*, a paper in which his large experience, wide reading, sound judgment, and broad and scientific views appeared to great advantage.

Dr. Van Buren was preëminently a painstaking man. Whatever he did was done thoroughly and to the best of his ability. He was never careless or hasty in his work. He brought to his daily practice as well as to the preparation of his papers and lectures, his full and earnest attention, all the powers of a mind and judgment that were constantly strengthening by study and exercise, and a very keen sense of professional responsibility. His powers of analysis and exposition were remarkable. His success as a lecturer was of the highest order, and the intrinsic value of his written work was embellished by the accuracy, grace, and polish of his language.

As an operator, he is ranked among the first, by those who were familiar with his practice during the more active part of his career. The same extent and accuracy of knowledge; the deliberation, neatness, and grace of execution, which characterized his other work appeared also in this, and his sound judgment, fertility of resource, promptness of decision, and self-reliance carried him not only safely, but even brilliantly, through the most trying emergencies. It was a revelation even to see him pass a catheter, to see him bring even to that simple act so much dexterity, gentleness of touch, keenness of observation, and attention to detail. Notwithstanding the possession of all these qualities and his success as an operator, he disliked to use the knife, and he never resorted to it unless the indications were imperative; his counsel in this respect always leaned to the side of conservatism.

His mind was not a nimble one; he thought slowly and deliberately, but he thought well and deeply. His perception was keen, his observation close and far-reaching, his grasp of a subject broad and strong; his mind never rested on details, but always sought the deeper cause, the broader generalization. These qualities were familiar to all who sought him in consultation, and are to be recognized in his printed works, and in his influence upon the general conception and treatment of the specialties with which he was identified. At the same time, he had a very lively sense of the value of details, especially in treatment, and he devised some very valuable and ingenious additions to the surgical armamentarium.

In person, he was a large, handsome, dignified man, with whom no new acquaintance would be familiar, whom no one would treat without respect. Quiet and self-contained in manner, scrupulously neat and careful in person and dress, he always appeared for what he was—a gentleman by birth and breeding. When he gave his trust he gave it completely, and his judgment of character was seldom at fault, his confidence rarely abused. His sense of professional responsibility was great, and while he often refused to take a new case, he never neglected one that was under his care. Even within a few years, after he had long ceased to visit in practice, and at a time when he was guarding his failing health most carefully, he has left his bed at midnight and driven ten miles to answer a call from a gentleman who had had a chill after the passage of a catheter in his office, in the morning. And often when consulted in a case, even a hospital one, which he had turned over to another, he would say, "Well, I suppose I have some responsibility in the matter; I will see him with you."

His acquirements, outside of his profession, were considerable; his literary tastes and habits strong and cultivated. He had a good knowledge of French, some knowledge of German, and occupied a portion of his leisure in reading the Latin classics, while his acquaintance with the best English literature was wide and accurate. His extensive knowledge, scholarly tastes, quick humor, and fertile fancy made him a delightful companion, and almost his last words, as he was sinking into the unconsciousness that preceded his death, were a playful affectionate recognition of one who has been to him for many years as devoted as a son.

"He was a man, take him for all in all,
I shall not look upon his like again;"

NEWS ITEMS.

RICHMOND, INDIANA.

(*From our Special Correspondent.*)

EPIDEMIC OF MEASLES.—Richmond, Indiana, was invaded by an epidemic of measles, continuing through the last four months of 1882, wherein there was an extraordinary large number of cases, and but few deaths. The County Health Officer reports 3,536 cases of measles in a population of 15,543, with but 12 deaths from measles directly, 3 deaths from whooping-cough following measles, and 1 death from croup following measles.

LONDON.

(*From our Special Correspondent.*)

URINE-TESTING.—At the last meeting of the Clinical Society of London the important subject of urine-testing was brought up by Dr. George Johnson. Already at the Pathological Society Drs. Pavy, Oliver, and Ralfe have this session given demonstrations of new tests, etc. Dr. Ralfe's communication was of considerable importance. It was to the effect that, although picric acid, ferrocyanide of potassium, and the other new tests are valuable as affording us means of detecting very minute traces of albumen, yet they are imperfect, as not by themselves distinguishing between the different forms of albumen found in urine. He showed—1. That urine precipitated by ferrocyanide of potassium, and also coagulated by heat, contained serum albumen. 2. Urine precipitated by ferrocyanide of potassium, and not coagulated by heat till citric acid be added, contains alkali-albumen, or casein. 3. While if the addition of carbonate of sodium be necessary before coagulation by heat occurs, the albumen is in the form of acid-albumen or syntonin. 4. Urine coagulated by ferrocyanide of potassium, and not precipitated by heat at all, but giving a red color with an alkaline solution of copper sulphate, contains parapeptone. Heat, therefore, must be employed in all cases where the more delicate tests have shown the presence of albumen, to determine what form that albumen is present in. This knowledge throws much light upon the other conditions of the urine.

A Case of Fracture of the Radius and Dislocation Forwards of the Ulna at the Wrist, in which the Lower End of the Latter Bone was Removed to Effect Reduction.—Mr. R. I. Godlee, at the same meeting, related the history of a patient, aged twenty, who was jumping a high jump at a gymnasium, when his feet slipped forwards on a badly secured mat, and the whole weight of his body fell suddenly on his hands, which were placed behind him. The left radius was fractured at the junction of the middle and lower thirds, the *upper end* of the fracture being compound; the lower end of the ulna was displaced forwards and projected in front of the carpus beneath the skin. All attempts at reduction with or without an anæsthetic proved unsuccessful. An incision was made over the lower end of the ulna, and a hook was placed under the tendon of the carpi ulnaris, which had slipped behind the bone; but the bones could not be replaced until first the styloid process and then the lower end of the ulna had been sawn off. The wound was treated antiseptically, and healed without any inflammatory disturbance. In ten days it was placed in a plaster-of-Paris apparatus, and in about six weeks passive movement was commenced. The limb is now about as useful as the other, and can be employed for gymnastic exercises as well as for the ordinary uses of daily life; but pronation is not quite as free as before. The patient was shown.

Mr. Clement Lucas stated that he had excised the lower end of the ulna, and the case recovered without any adduction; this he believed to be due to the greater power of the abductor muscles.

Mr. C. Heath said that he had had a similar experience, and thought the operation of excision of the lower end of the ulna a very good one.

Mr. R. I. Godlee replied that there was no adduction of the hand in cases of congenital absence of the ulna, and this he explained by the fact that the carpus articulated with the radius, not the ulna.

Acute Necrosis of the Right Orbital Plate of Frontal Bone.—Dr. Pearson and Dr. Broadbent reported at the same meeting a case of a girl, æt. nine years and eight months, in whom four days after exposure to cold on a foggy November afternoon, symptoms of stiff neck, relaxed throat, causing restless nights, began, but so gradually that medical attendance was not called in till the fourth day. When first seen, the noticeable point in the case was that the child put both hands to her head to lift it when asked to sit up in bed. On the fifth day of the disease there was marked improvement, after a saline aperient and four-grain doses of salicylate of sodium every four hours. In the morning the right upper eyelid had got puffy, but the swelling went down again. There were slight droppings of blood from the nose three separate times during the day. On the sixth day, after a restless night, with some wandering, followed by a morning sleep of two and a half hours, the child woke up sufficiently well to listen to fairy tales and talk about them. She felt the neck so much better that she volunteered to get out of bed alone to show her throat, but still holding one hand lightly to the head. There was some sensitiveness to light, and the right eyelid was again puffed. The same evening great restlessness set in, the child throwing the legs and arms about and calling out. The tumefaction of the right eyebrow had now markedly increased, and there was strong delirium. The temperature at 11.30 P. M. was 103.3°, pulse 140, respiration 38. Bromide of potassium was added to the salicylate mixture, and, after a sleep of an hour and twenty minutes, the pulse was 120, and temperature 101.6°. On the seventh day the right eyebrow was quite tense and glazed, and livid with tumefaction, and delirium continued. At 10 A.M. the temperature was 104.° Two leeches were applied to the right temple, and three grains of calomel were given, to be followed by a saline purge. Towards evening the strength perceptibly diminished. Just after midnight the pulse was 138, respiration 52, temperature 105.7°. At 4.30 A. M., temperature 106.4°; 6.30 A. M., temperature 107.7°; at 9.45 A. M., temperature 107.9°; and death took place at 10.45 on the morning of the eighth day from the commencement of symptoms.

Post-mortem examination, five hours after death.—At once on removing the scalp, the frontal portion of the longitudinal sinus showed itself over-charged, staining the periosteum externally. On lifting the brain, the dura mater covering the petrous portion of the right temporal bone was found smeared with thick yellow lymph. The same lymph smeared the pons and the parts comprised in the circle of Willis. The right temporo-sphenoidal lobe of the brain was protuberant, due to serous infiltration from obstruction to the venous return. The right optic nerve and the fat surrounding it were stained with the same clinging yellow lymph. The periosteum of the right orbital plate of the frontal bone was stained with inflammation, and destroyed in patches.

Mr. Pearce Gould asked if any pulsation was at any time noticed in the orbital swelling, as thrombosis of the cavernous sinus was stated to be one of the causes of pulsating exophthalmos, although that condition was at any rate more generally due to arterio-venous communication.

Mr. J. Black asked if the swelling fluctuated, and whether an incision would have been of any avail.

Dr. Mahomed referred to a similar case in which the septic nature of the affection was shown after death by the presence of numerous abscesses in the brain.

Dr. Broadbent replied that there was neither pulsation nor fluctuation in the swelling. The orbital periosteum was intact, and the effusion within it was serous. The dura mater was pierced in several places. He had considered that the free mobility of the eye, and entire absence of proptosis excluded any inflammatory effusion within the orbit.

On Picric Acid as a Test for Albumen and Sugar in the Urine.—The following is an abstract of Dr. George Johnson's paper on this interesting subject, also presented at this meeting of the Clinical Society:

Although picric acid has for ten years or more been used as a test for albumen in the urine, its value has not been fully appreciated. It may be used in the form of a saturated aqueous solution, made by dissolving the crystals in about fifty times their volume of boiling water, or in the form of powder, which may conveniently be carried in a pocket-case.

The solution poured on the surface of the urine in a sloping test-tube will cause opalescence in a specimen of albuminous urine diluted much beyond the point at which nitric acid fails to act. The powder of crystals equal in bulk to a pepper-corn, when shaken up with about a drachm of urine will be dissolved, and immediately coagulate any albumen present.

Picric acid boiled with a solution of potash is a most delicate test for glucose. The reduction of yellow picric to the deep red picramic acid by glucose when boiled with potash, although noticed by Bram nearly twenty years ago, appears not to have been utilized as a practical test; ʒj of a solution of grape sugar (gr. j to ʒj) is mixed with ʒss of liquor potassa (B. P.) in 10 of a saturated solution of picric acid and made up to ʒiv with distilled water. The mixture is placed in a boiling tube ten inches long and three-quarters of an inch wide, having a mark made at the height of ʒiv. It is then heated to the boiling-point and kept boiling for sixty

seconds. The resulting color indicates gr. $\frac{1}{4}$ sugar to $\overline{3}$j. This color may be exactly imitated by a solution of acetate of iron with excess of acetic acid, which is used as a standard in making a quantitative analysis. The depth of color is directly proportioned to the amount of sugar present to decompose the picric acid.

When the color is deeper than the standard, the dark liquid is diluted until it and the standard have the same tint. The dilution is effected in a tube twelve inches long, divided into equal $\frac{1}{10}$ and $\frac{1}{100}$ parts. By the side is a tube of equal size containing the standard color.[1] A more exact comparison of the colors is made by looking through equal columns of the saccharine liquid and the standard in flat-bottomed tubes held over white paper or porcelain. Ten minims of solution of picric acid are rather more than equivalent to the sugar ($\frac{1}{8}$ gr.) in $\overline{3}$j of a solution containing gr. j to $\overline{3}$j

In making an analysis, the picric acid must be in proportion to the amount of sugar. If the proportion of sugar be as high as six grains to the ounce, about a drachm of solution of picric acid will be required for a drachm of the sugar solution. When the amount of sugar is more than six grains to the ounce, the liquid should be diluted in a definite proportion before it is analyzed. Distilled or pure rain water is used for dilution. Hard water becomes turbid when mixed with caustic potash. If undiluted urine is rendered turbid by phosphates in process of testing, it should be cleared by filtration. The measurements and dilutions must all be accurate.

The presence of albumen, even in large amount, does not interfere practically with the picric acid test. The accuracy of the test is proved by practically identical results from analyzing the same specimens by Dr. Pavy's ammonio-cupric solution, and by picric acid and potash. Some tabular statements of results are given.

An analysis of about three hundred specimens of normal urine by the picric acid process indicates the constant presence of a substance capable of reducing picric acid and cupric oxide in proportions equivalent to from 0.5 to 0.7 grain of glucose per ounce, but apparently differing from glucose in the fact that it cannot be made to undergo the vinous fermentation under the influence of heat.

DR. SOUTHEY and MR. MCHARDY both spoke of the great delicacy of the picric acid test for albumen, and the former said that urine which must be considered normal often contained albumen.

DR. JOHNSON doubted very much whether even the smallest traces of albumen are found in urine as a physiological result.

SIR JOSEPH FAYRER took the chair at the meeting of the Medical Society of London for the first time as the newly elected President. He announced that next week Dr. Manson, of China, will exhibit to the Society a newly discovered parasite—*Distoma Ringeri*—and will read a paper on the disease caused by it—endemic hæmoptysis.

THE ERICHSEN TESTIMONIAL.—On Saturday, March 10, at a large gathering of Professor Erichsen's old pupils and friends, he was presented by them with a marble bust of himself by Thornycroft, and a purse of money, which he at once gave to University College, to found in perpetuity a Prize for Operative Surgery.

INVESTIGATION OF CATTLE DISEASES.—A press dispatch from Washington states that Dr. D. E. Salmon, who has been for several years employed by the Department of Agriculture to conduct investigations into the diseases of swine and poultry, has been called to Washington by Commissioner Loring, to conduct like investigations on a more elaborate scale. Land is to be leased, and animals provided for experiments on inoculation, etc., and the Pasteur system of inoculation will be adopted with such additions and modifications as have been suggested by Dr. Salmon's own discoveries and experiences. The investigation will be conducted with a special view of ascertaining the nature, and the means of prevention and cure of Texas cattle fever, pleuro-pneumonia, and hog and chicken cholera. The results of the researches already made by Dr. Salmon are such as to make him feel reasonably confident that he will eventually be able to discover remedies which will enable any farmer to prevent or cure the diseases mentioned.

THE PROTECTION OF MEMPHIS FROM YELLOW FEVER.—According to a press dispatch, owing to the unsatisfactory condition of the laws governing quarantine at the mouth of the Mississippi, the authorities of Memphis have determined to inaugurate a system of precautionary measures that will enable them to prevent the introduction of contagious diseases during the summer months. A few days ago President Holden, of the Legislative Council, petitioned the State Legislature for an appropriation to defray the expenses of local quarantine in case of necessity, and the President of the City Board of Health has issued a proclamation warning the citizens that a thorough house-to-house inspection would begin Monday, and every building, front and back yards, outhouses, stables, etc., would be thoroughly examined, with a view to having them put in the most complete sanitary condition.

The President of the Council backs up the proclamation with the warning that the owners of unsanitary premises will be punished to the fullest extent of the law for violations of the sanitary ordinance. This system of inspection will be continued throughout the summer, and until all possibility of danger is passed. The first intimation of yellow fever or other contagious diseases, at New Orleans or other points on the lower Mississippi, will be the signal for the establishment of a rigid quarantine against the places. The troubles of 1878 and 1879 have not been forgotten, and the authorities are determined that they shall not be repeated, if it is in the power of man to prevent them.

AMERICAN LARYNGOLOGICAL ASSOCIATION.—The Fifth Annual Convention of the above Association will be held in the hall of the Academy of Medicine, No. 12 West Thirty-first Street, New York City, commencing Monday, May 21, 1883, at 10 A. M., and continuing during the two following days.

MEETINGS OF STATE MEDICAL SOCIETIES.—The Kentucky Medical Society will hold its annual meeting on April 4th, and on the same day the Mississippi State Medical Society will meet at Meridian, and the Louisiana State Society at Shreveport.

COMMENCEMENT OF THE IOWA COLLEGE OF PHYSICIANS AND SURGEONS.—The Iowa College of Physicians and Surgeons held its commencement March 6th, and granted diplomas to three graduates.

THE DISPENSARY OF THE PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES IN MEDICINE has treated during the first two weeks of its existence 397 patients.

LECTURES UPON MATERIA MEDICA AT THE U. S. NATIONAL MUSEUM.—Dr. D. W. Prentiss has been invited to deliver a course of lectures in connection with the department of Materia Medica of the National Museum.

[1] This picro-saccharimeter was made by E. Cetti, 36 Brooke St., Holborn, E. C.

The course will consist of eight lectures, and will be illustrated by specimens and other material from the collections of the Museum.

The lectures will be delivered at 4 o'clock on successive Saturday afternoons, beginning Saturday, April 7.

These lectures are free. Persons desiring to attend must be provided with tickets, which may be obtained by application through the mail or in person, to Mr. S. C. Brown, Registrar of the Museum.

CINCINNATI TRAINING SCHOOL FOR NURSES.—A school for the systematic training of nurses has been started in Cincinnati, under the presidency of Dr. Geo. B. Orr.

A NEW NEW YORK STATE MEDICAL SOCIETY.—The conviction that this State must have a medical society, in affiliation with the American Medical Association and the best physicians of this country and Europe, is becoming more general and profound. That the merest fraction of the medical corps of this State is to dominate the entire body, to disrupt, degrade, and disgrace it, no one can believe; and physicians of the State will deserve ruin and disgrace if they passively submit to be thus outraged and trampled upon. It needs but a strong "call," and the new State Society, supported by the whole country, and all the medical press (two journals excepted), would spring into vigorous being.—*Gaillard's Med. Journal*, March 10, 1883.

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending March 17, 1883, indicate that bronchitis and pneumonia have decreased in area of prevalence. There was no marked increase in any disease reported.

Including reports by regular observers and by others, diphtheria was reported present during the week ending March 17, and since, at sixteen places, scarlet fever at eighteen places, and measles at fourteen places. No smallpox reported in Michigan.

PROF. NEUMANN, the successor to the chair of the late Professor von Sigmund, in the University of Vienna, on February 8, delivered an eloquent eulogy of his predecessor, in which he claimed for him the honor of first having instituted a systematic clinic of his specialty.

PROF. V. BERGMANN, who for some weeks has been incapacitated from his duties on account of sickness, has now entirely regained his health.

PROF. V. BERGMANN'S SUCCESSOR.—PROF. MAAS has been appointed Professor of Surgery in Würzburg, in the place vacated by the resignation of Prof. Bergmann.

PROF. VON ARLT has been decorated with the star of a Commander of the Order of Francis-Joseph.

THE LIBRARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY of London contains 33,500 volumes.

SANITARY EXHIBITION AT BERLIN, GERMANY.—It will be remembered that it was the intention of the German authorities to open a Hygienic Exhibition, in Berlin, in May of last year. Unfortunately, however, a few days before the proposed opening the magnificent building, which had been constructed for the purpose of the exhibition, was destroyed by fire. This caused a temporary suspension of the whole matter, but the deep interest felt in the success of such an undertaking by the Emperor, Empress, Crown Prince, and medical and scientific men, has tended to so strengthen the committee having the matter in charge, that new buildings have been constructed and enlarged, and improved accommodations made for such an exhibition; and it is now expected that it will be ready to be opened on the first day of May next.

DRAIN-TESTING.—The Sanitary Inspector for Glasgow reports that of 236 properties, the drains of which were examined last year, only seven were found thoroughly tight and efficient—229 permitting the escape of sewer-air into the dwellings.

ASTLEY COOPER PRIZE.—The next triennial prize of $1500 will be awarded to the author of the best essay or treatise on "Diseases and Injuries of the Nerves and their Surgical Treatment, together with the operations performed upon nerve-trunks in the treatment of various diseases, and descriptions of the changes which ensue in other structures as well as in the nerves themselves from these operations." The condition annexed by the testator (the late Sir Astley P. Cooper, Bart.) is, "That the essays or treatises to be written for such prize shall contain original experiments and observations which shall not have been previously published, and that each essay or treatise shall (as far as the subject shall admit of) be illustrated by preparations and by drawings, which preparations and drawings shall be added to the museum of Guy's Hospital, and shall, together with the work itself, and the sole and inclusive interest therein and the copyright thereof, become henceforth the property of that institution, and shall be relinquished and transferred as such by the successful candidate." The essays must be written in the English language, or, if in a foreign language, accompanied by an English translation, and must be sent to Guy's Hospital on or before January 1, 1886, addressed to the physicians and surgeons of Guy's Hospital.—*Lancet*, March 10, 1883.

PRIZE FOR THE SOLUTION OF THE QUESTION AS TO THE PREVENTION OF POLLUTION OF RIVERS.—The King of Saxony offers a prize of a silver "jardinière," with nine hundred marks, to be awarded by the German Fishery Commission for the best essay on "The Pollution of Water-courses and its Prevention, with special reference to the Maintenance of the Life and Health of Fish."

Essays are to be sent to Dr. P. Boerner, 8 Burggrafen Strasse, Berlin, W., before December 31, 1884, from whom further information may be obtained.

COMPLIMENTARY DINNER TO DR. OLIVER WENDELL HOLMES.—The leading members of the medical profession of New York will give a complimentary dinner to Dr. Oliver Wendell Holmes at Delmonico's, Thursday evening, April 12. It is tendered as an expression of appreciation of the honor Dr. Holmes has won for American medical and general literature during the past forty years.

NEPHRECTOMY.—This rare operation was performed at the Queen's Hospital, Birmingham, on March 3d, by Mr. West, and the case was reported on the 7th to be doing well. The patient on whom the operation was performed was a boy, aged fifteen, who, on last Guy Fawkes day, sustained a traumatic rupture of the left kidney. Suppuration ensued, and for this aspiration and then free incision were employed; but as the boy was discharging about eighty ounces of putrid ammoniacal urine mixed with pus through the loin, and as he was getting into a hectic condition, Mr. West decided to remove the kidney. The kidney was of great size, and was full of suppurating cysts.—*Lancet*, March 10, 1883.

LEPROSY IN HAWAII.—The *Commercial Advertiser* of Honolulu, referring to reports of the general spread of leprosy in Hawaii, says: "The districts of Wailuka, Waikee, Wakawas, and Ulspalakua, of the island of Wauai, comprising an area of 300 square miles of the most densely populated portion of the kingdom, with 10,000 inhabitants, have been thoroughly searched for lepers by the Board of Health. The result was that twenty-eight native and no foreign lepers were found. There are ten foreign lepers at the leper settlement at Molokai, most of whom contracted the disease by licentiousness."

BOSTON PLUMBING ORDINANCE.—The following is the text of the ordinance regulating plumbing in the city of Boston, which passed the City Council the 16th inst., and has received the Mayor's signature.

"SECTION 1. No person shall carry on the business of plumbing unless he shall have first registered his name and place of business in the office of the Inspector of Buildings, and notice of any change in the place of business of a registered plumber shall be immediately given to said Inspector.

"SECT. 2. Every plumber, before doing any work in a building, shall, except in the case of repairs or leaks, file at the office of the Inspector, upon blanks to be provided for the purpose, a notice of the work to be performed; and no such work shall be done in any building without the approval of said Inspector.

"SECT. 3. Every building shall be separately and independently connected with the public sewer, when such sewer is provided; and, if such sewer is not provided, with a brick and cement cesspool of a capacity to be approved by the said Inspector.

"SECT. 4. Drains and soil-pipe through which water and sewage are used and carried shall be of iron, when within a building, for a distance of not less than five feet outside of the foundation walls thereof. They shall be sound, free from holes and other defects, of a uniform thickness of not less than one-eighth of an inch for a diameter of four inches or less, or five-thirty-seconds of an inch for a diameter of five or six inches, with a proportional increase of thickness for a greater diameter. They shall be securely ironed to walls, laid in trenches of uniform grade, or suspended to floor-timbers by strong iron hangers, as the said Inspector may direct. They shall be supplied with a suitable trap, placed, with an accessible clean-out, either outside or inside the foundation wall of the building. They shall have a proper fall towards the drain or sewer, and soil-pipes shall be carried out through the roof, open and undiminished in size, to such height as may be directed by said Inspector; but no soil-pipe shall be carried to a height less than two feet above the roof. Changes in direction shall be made with curved pipes, and connections with horizontal pipes shall be made with Y-branches.

"SECT. 5. Rain-water leaders, when connected with soil or drain-pipes, shall be suitably trapped.

"SECT. 6. Sewer, soil-pipe, or waste-pipe ventilators shall not be constructed of brick, sheet-metal, or earthen-ware, and chimney-flues shall not be used as such ventilators.

"SECT. 7. Iron pipes, before being put in place, shall first be tested by the water or kerosene test, and then coated inside and out with coal-tar pitch, applied hot, or with paint, or with some equivalent substance. Joints shall be run with molten lead, and thoroughly calked and made tight. Connections of lead pipes with iron pipes shall be made with brass ferules, properly soldered and calked to the iron.

"SECT. 8. Every sink, basin, bath-tub, water-closet, slop-hopper, and each set of trays, and every fixture having a waste-pipe, shall be furnished with a trap, which shall be placed as near as practicable to the fixture that it serves. Traps shall be protected from siphonage or air-pressure by special air-pipes of a size not less than the waste-pipe; but air-pipes for water-closet traps shall be of not less than two-inch bore for thirty feet or less, and of not less than three-inch bore for more than thirty feet. Air-pipes shall be run as direct as practicable, and shall be of not less than four-inch bore where they pass through the roof. Two or more air-pipes may be connected together or with a soil-pipe; but in every case of connection with a soil-pipe, such connection shall be above the upper fixture of the building.

"SECT. 9. Drips or overflow pipes from safes under water-closets and other fixtures, or from tanks or cisterns, shall be run to some place in open sight, and in no case shall any such pipe be connected directly with a drain, waste-pipe, or soil-pipe.

"SECT. 10. Waste-pipes from refrigerators or other receptacles in which provisions are stored, shall not be connected with a drain, soil-pipe, or other waste-pipe, unless such waste-pipes are provided with traps, suitably ventilated, and in every case there shall be an open tray between the trap and the refrigerator.

"SECT. 11. Every water-closet, or line of water-closets on the same floor, shall be supplied with water from a tank or cistern, and the flushing pipe shall not be less than one inch in diameter.

"SECT. 12. Pipes and other fixtures shall not be covered or concealed from view until after the work has been examined by the said Inspector, and he shall be notified by the plumber when the work is sufficiently advanced for inspection.

"SECT. 13. Plumbing work shall not be used unless the same has first been tested by the said Inspector with the peppermint, ether, or water test, and by him found satisfactory.

"SECT. 14. No steam-exhaust shall be connected with any soil or waste-pipe, or drain which communicates with a public sewer.

"SECT. 15. Water-pipes in places exposed to frost shall be packed with mineral wool, or other substances equally good, and they shall be cased to the satisfaction of the said Inspector.

"SECT. 16. A grease trap shall be constructed under the sink of every hotel, eating-house, restaurant, or other public cooking establishment.

"SECT. 17. The provisions of Sections 3–13, inclusive, and of Section 15 of this ordinance, shall apply only to buildings erected, or to work performed, after its passage."—*Sanitary Engineer*, March 22, 1883.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 19 TO MARCH 26, 1883.

BURTON, HENRY G., *Captain and Assistant Surgeon.*—To be relieved from duty in the Department of the East, and will report in person to the commanding general Department of Dakota, for assignment to duty.—*Par. 1, S. O. 67, A. G. O., March 22, 1883.*

PORTER JOSEPH Y., *Captain and Assistant Surgeon.*—To be relieved from duty in the Department of the South, and will report in person to the commanding general Department of Texas, for assignment to duty.—*Par. 1, S. O. 67, A. G. O., March 22, 1883.*

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia*

ORIGINAL LECTURES.

GASTRIC CANCER;

THE DIAGNOSIS BETWEEN CANCER OF THE STOMACH AND CANCER OF THE PANCREAS; RECTAL ALIMENTATION AND THE USE OF ARTIFICIALLY DIGESTED FOOD.

A Clinical Lecture, delivered at the Philadelphia Hospital, January 31, 1883.

BY JAMES TYSON, M.D.,

PROFESSOR OF GENERAL PATHOLOGY AND MORBID ANATOMY IN THE UNIVERSITY OF PENNSYLVANIA, AND ONE OF THE ATTENDING PHYSICIANS TO THE PHILADELPHIA HOSPITAL, ETC.

(Reported by WILLIAM H. MORRISON, M.D.)

GENTLEMEN: Before making a personal examination of this patient, I wish to call your attention to her extremely cachectic appearance. This is seen not only in the pallor of her face, but also in the almost bloodless condition of her lips. The little bloodvessels, which, seen through the transparent mucous membrane, give the red color to the lips, are either almost empty, or filled with blood which is deficient in red corpuscles.

As to her history, she is forty years of age; is married; her husband living; she has had two children. Three years ago a hard lump appeared at the left angle of the mouth. This gradually ulcerated, and was removed two years ago by Dr. Wilson, at the Woman's Hospital. The growth, she tells us, was pronounced a cancer. The scar left by its removal is still visible, but there has been no reappearance of the disease *in loco*. Before the operation there had been a gradual failure of strength and weight, and instead of her general condition improving after the removal of the tumor, it seemed rather to continue to fail.

She was admitted to the hospital September 15, 1882. At that time she complained of dyspepsia. The indigestion was characterized by acidity and the disposition to discharge acid fluid. This was the only trouble complained of. The efforts to counteract this acidity by the ordinary alkaline mixtures were but partially successful, and it was only by the use of large quantities of lime-water and other alkalies, and the final adoption of a pure-milk and lime-water diet, that this acidity was relieved sufficiently to secure her tolerable comfort, and at present she does not suffer much from this symptom. There soon supervened upon this condition a tendency to nausea, and a disposition to vomit. In this vomiting there was not, nor has there been since, anything like regularity, nor a fixed relation to the meals. Large quantities have never been vomited, and this has never been a troublesome symptom. The matters discharged were usually an acid fluid and partially digested food; occasionally, however, she vomited matters different from those described, and to these I shall refer in a few moments. There has also been some constipation, not obstinate constipation, for the bowels are easily relieved by ordinary aperient remedies.

As to the second kind of vomited matters, she tells us that they consist of a substance resembling coffee grounds. She says that last night, for instance, she vomited a teacupful of this brown substance, which, in her own language, looks like the sediment which remains in the cup after the coffee has been drained off. This description is spontaneous, and, although we have never seen the substance, I do not think we dare doubt its nature. It is altered blood. The vomiting of this occurs at very irregular intervals, sometimes every week, and sometimes only once a month. She says that this peculiar vomiting occurred even before she came to the hospital. This, then, is her history so far as subjective symptoms are concerned.

On her admission we were impressed by her extreme pallor, and therefore frequently examined the abdomen for a tumor. She was also carefully examined for uterine cancer, but none was found, and there is no other disease of the womb. In the absence of anything distinctive in the symptoms, leukhæmia suggested itself, and I had the blood examined by Dr. William E. Hughes, who reports that he found in a cubic millimetre of blood 1,999,000 red corpuscles, and 15,000 white corpuscles—one white to about 133 red. The red corpuscles were also small, but the disproportion between the two kinds was not considered sufficient to justify a diagnosis of leukhæmia.

About the middle of November the looked-for aid to diagnosis presented itself—a tumor. This is now much more distinct than it was then. Even at a considerable distance you can see an elevation of the triangular space included between the lower border of the ribs and a line drawn from the angle of this border on the right side, through the umbilicus almost to the superior spinous process of the ilium on the left. In addition to this diffuse swelling there is a distinct tumor, nearly circular in outline and about two and a half inches in diameter, just to the left of the umbilicus; that is, a line drawn vertically through the umbilicus bounds the right edge of the tumor as a tangent does a circle, the mass of the tumor being to the left. I should have stated earlier that soon after admission, that is, about October 1st, there was not only tenderness in this region, but she also complained of pain independent of pressure, although no tumor was detected until a month later.

Let me briefly recapitulate the symptoms:

An intensely anæmic woman has suffered for some time from gastric symptoms, these symptoms being almost constant acid dyspepsia and a disposition to vomit, the vomiting occurring at irregular intervals and with no definite relation to the meals. Occasionally there has been vomiting of altered blood. There is a circumscribed tumor to the left of the umbilicus. The question as to what is the matter, is immediately answered by the suspicion, that it is a case of cancer of the stomach. There are, however, some doubts upon this point, and it is partly for the purpose of trying to determine this question that I brought her before you to-day. While many of the symptoms of cancer of the stomach are present, some of the most distinctive are wanting. One of these is obstruction of the pylorus. There is no symptom of obstruction at this situation. In the vast majority of cases of cancer of the stomach, the pylorus is the point affected—in fact, the pyloric orifice of the stomach is, next to the uterus, the most frequent seat of carcinoma. There may of course be cancer of the cardiac orifice with obstruction, but under such circumstances the food is regurgitated immediately after ingestion and little altered. On the other hand, when the obstruction is at the pylorus, the vomiting comes on a couple of hours or even longer after a meal. It may not occur for several days after

the food has been taken, but the longer the interval the greater the amount vomited. This is owing to the fact that the stomach becomes gradually dilated, and the longer the case lasts the less frequent is the vomiting. I recall an instance of cancer of the pylorus, in which this was particularly marked. In this patient the vomiting was sometimes at intervals of ten days, and then a bucketful was ejected. At the autopsy, there was found cancer of the pylorus with great dilatation of the stomach, from which I removed at the time of the post-mortem examination over a gallon of fluid. In the present case there has been nothing of this kind.

Let me again refer to the situation of the tumor, which lies to the left of the umbilicus. This, is, however, not inconsistent with the view that there is cancer of the pylorus. I have several times called attention to this fact. If you examine the books, you will find that they state that the most frequent situation of the tumor in cancer of the pylorus is in the epigastric region, a little to the right of the median line, and below the free border of the ribs. I do not know how many cases of this disease I have seen, but in at least half a dozen the tumor was exactly in the position occupied by the mass in this case. In the patient with the enormous dilatation just alluded to, the tumor was in the same situation, but a little to the right. At present, I recall no case in which the tumor has not been in the umbilical region. The situation of the pylorus in health cannot be said to be fixed, but it is probably most frequently to the right of the median line, and a couple of inches below the ribs. I cannot but think that writers have been misled by this normal position, to expect that a tumor of the pylorus is always found in the same place. But it must be remembered that the tumor soon acquires weight, and that the stomach is easily displaced; to such displacement dilatation often contributes. Apart from this, if you examine the position of the pylorus after death, in cases where there has been no disease of the stomach, you will find that it is not constant, and that it is as frequently to the left of the median line as to the right. So that, although we find the tumor in this position, we have in this fact nothing to diminish the probability of this disease being cancer of the pylorus; the strongest point against cancer of the pylorus being the fact that there is no obstruction.

What else could it be? The most likely disease after cancer of the stomach, would be cancer of the pancreas. I have seen two or three cases of cancer of this organ, in which the tumor occupied this situation. In a case which I had a year ago, there was a tumor in precisely this situation. The autopsy proved it to be cancer of the pancreas, as had been suspected before death. Is there anything which will help us in this dilemma? In the first place, in a large proportion of cases of cancer of the pancreas, there is jaundice; there is no jaundice in our patient. Again, in cancer of the pancreas there are symptoms of indigestion, which resemble those present in this patient more than they do those of typical cancer of the stomach, excepting the vomiting of blood, which does not occur in pancreatic cancer. In the latter there is a tendency to diarrhœa, and frequently the liquid stools contain fat; sometimes this is very manifest. In the case to which I have just alluded, the diagnosis was made from the presence of indigestion with irregular vomiting, and the characteristic condition of the stools. By the use of opium, bismuth, etc., the diarrhœa is checked for a time, but in a few days the liquid discharges seem to burst through a barrier which held them temporarily in check. In the patient before you to-day, there is but one of these symptoms, *i. e.*, indigestion. The stools have been carefully examined, but no fatty matter has been found; neither is there any diarrhœa. There is on the other hand, some constipation, although it is not as marked as in cancer of the pylorus with obstruction. Balancing these facts, therefore, the probabilities are in favor of the presence of cancer of the pylorus, notwithstanding the absence of the most valuable symptoms of obstruction.

Cancer involving other portions of the stomach does not produce a circumscribed tumor such as we have here. The cancers affecting the greater and lesser curvatures are diffuse growths and soft cancers, whereas those at the pylorus are circumscribed tumors and epithelial or schirrous cancers in nature.

The question of *treatment* is an important one. For although it is impossible to do anything to remove the growth, we should not, at the same time, be apathetic in the matter, and I am quite sure that a good deal more can be done than is commonly thought possible. As a rule, the food taken into the stomach is sooner or later rejected; but this is partly because the stomach is disqualified to prepare it; to reduce it, by digestion, to the liquid state it must have to enable it to pass through the pylorus. Now if we can digest the food partially or altogether, before it is put into the stomach, we obviate this difficulty. Still better will we accomplish our purpose if we can introduce it partially or wholly digested into the rectum.

The stomach has no use outside of the preparation of the food for digestion. It is not a vital organ in the sense that the heart and the lungs are vital organs. It is important so far as it prepares the food, but if the food can be prepared for absorption outside of the body, its necessity is diminished, as it also is, if we introduce this artificially digested food into the rectum. Or we may use both of these methods. We can, by the use of prepared food, diminish the labor of the stomach, and by using the prepared food by the rectum, we can relieve the stomach of all labor. This is being done of late by peptonized foods of various kinds. The food may be prepared by the *extractum pancreatis*, which is now made by a number of pharmacists. Three to five grains of the extract added to a pint of milk and placed at a temperature of 100°, will in one hour peptonize all the casein. A curd is first produced, which subsequently undergoes digestion. The addition of rennet will then not produce coagulation. Milk thus prepared makes little demand upon the stomach for digestion, and it can be introduced by the rectum with good effect. The peptonized milk has a peculiar bitter taste, and unless this bitterness is present the digestion is unaccomplished. The digestion will take place at a lower temperature than 100°, but it takes longer.[1]

I have had very satisfactory results from another method of preparing the food for use by enema, the only objection to it is that it is a little troublesome. I saw it suggested in 1876, but by whom I cannot now recall, and I have since frequently used it when the patient is to be maintained solely by enema. The plan is to take from one and a half to two pounds of beef with the fat removed, and from one-half to one pound of fresh pancreas. The pancreas is finely chopped and afterwards bruised in a mortar with tepid water at

[1] The following method, slightly modified from that usually recommended, after numerous trials by patients, has been found most satisfactory: Take one pint of skimmed milk, to which add one gill of water. Heat to 140° F. (a temperature at which the finger can be immersed for half a minute). After taking from the fire, stir in three grains of powdered pancreatine and fifteen grains carbonate of sodium. Place in a covered kettle or jug and roll up in a cosey (an ordinary gossamer water-proof coat answers admirably well), near a stove or register to keep warm. Let it remain thus for an hour and a half; it then resembles slightly thickened milk, but there is no curd. Pour it into a covered pitcher and set aside to cool in the open air. Thus prepared, it has the slightest perceptible tinge of bitterness, and is very palatable.

a temperature of 100°. It is then strained through a cloth. The juice thus obtained is intimately mixed with the meat, which has previously been chopped into small pieces. The product is next allowed to stand at a temperature of 100° for two hours; it is then ready for use. This amount suffices for two daily injections. The preparation decomposes very quickly, so that it has to be made fresh every day. I was surprised at what I accomplished by this method. In the man with the dilated stomach to whom I have referred, nothing could pass the pylorus, but during the use of daily enemata there occurred each morning an evacuation from the bowel as natural as though the patient were living on a mixed diet and digesting it properly. The extract of pancreas will probably answer as well as the method which I have described, but I have not had any experience with it.

In this connection, I want to call your attention to a little book by Dr. William Roberts, *On the Digestive Ferments, and the Preparation and Use of Artificially Digested Food.* After an account of normal digestion, he gives a description of the methods of preparing food by the use of these ferments. The method which I have just given you is not contained in this book.

The use of peptonized food is advantageous in many diseases, and especially in the diseases of children. Most cases of diarrhœa in children are due to indigestion, but by means of the extract of pancreas, we have the power to prepare the food for absorption thus lessening the labor of the stomach. The so-called *liquor pancreaticus* may be used for the same purpose, but I have had more experience with the extract.

By using this method of alimentation we can, in cancer of the stomach, prolong the life of the patient and make his condition less burdensome. But it occasionally happens that rectal alimentation does not appease the sense of hunger; and I have had patients who, in spite of all injunctions to the contrary, and who, knowing themselves that they would sooner or later reject it, would take food by the mouth.

It has been proven, over and over, that life can be sustained in this way. Not only have dogs been kept alive for months by rectal alimentation, but the same thing has been done with men. But where it is possible, the stomach should be made use of to some extent, and thus save the rectum.

ORIGINAL ARTICLES.

OBSERVATIONS ON OCCLUSION OF THE POSTERIOR NARES AS A RESULT OF NASAL CATARRH.

By ALEXANDER W. MacCOY. M.D.,
MEMBER OF THE PHILADELPHIA LARYNGOLOGICAL SOCIETY.

(*Read before the Philadelphia Laryngological Society.*)

So much has already been written during the past few years concerning the pathology and treatment of chronic nasal catarrh, that it is with no little hesitancy I offer my contribution to its study.

I should scarcely have an apology for offering this paper, were I less convinced that a new era had arrived in the successful management of what was, and, by some, is yet considered an incurable disease. The spirit of incredulity has so completely possessed the minds of many, that any one professing to cure chronic nasal catarrh runs the risk of being considered an enthusiast.

In our humid and variable climate, affections of the nasal mucous membrane are all but universal. In some cases of nasal catarrh, but little appreciable ill-effect results; in others, the progress is steadily onward from year to year, to one certain end—nasal occlusion, partial or complete. Between the beginning and the result, in these latter cases, there is a period of discharge of muco-purulent or serous secretion, which increases with each acute exacerbation during the winter and spring, but lessens considerably during the summer, and in some cases is almost absent.

The course of chronic nasal catarrh of the *hypertrophic* variety (of which variety alone I wish to speak in this paper) is undoubtedly of long duration, extending over many years, and in many persons appears to have been the companion of their lives.

After considerable observation, I am of the opinion that no hypertrophic condition of the nasal mucous tract arises in any case except from a long-continued and persistent coryza. Hypertrophic change cannot be present without previous inflammation: the hypertrophic tissue is the *result* of the persistent irritation—the *effect* of an ever-active *cause.*

Only during the last few years has the rapid development taken place in our knowledge of diseases of the nasal cavities.

To native investigators we are indebted for much of the advance in pathology and treatment, and, as a clearer understanding of the true anatomy of the parts has obtained, the pathology has become so clearly established, that the mind has no alternative but to accept it.

The *peculiar* anatomical characteristics present in the mucous membrane lining certain portions of the nasal cavities, were prominently pointed out by Kölliker and by Kohlrausch twenty-nine years ago, who described, in the sub-mucous layer, what they termed venous channels, great in size and very numerous—out of all proportion to what were known to exist in other mucous tissue. Kohlrausch's discovery was not attended by any practical results, because this anatomical knowledge was far in advance of his time, particularly as to its bearing upon nasal catarrh.

Twenty years after Kohlrausch had made his observations, Dr. Bigelow, of Boston, made a much more elaborate and successful study of this peculiar anatomy. While Dr. Bigelow's observations confirmed those of Kohlrausch, as to the enormous venous channels in the sub-mucous layer of the nasal cavities, he also proved that these sinuses constituted a true erectile tissue, such as is most clearly observed in the corpora cavernosa, capable of dilation and contraction.

Bigelow's investigations have been repeatedly confirmed by observers in recent years. To these later observations are we indebted for refreshing our memory concerning this unique structure, and most of all, concerning the practical bearing which this information has had in building up so clear a pathology.

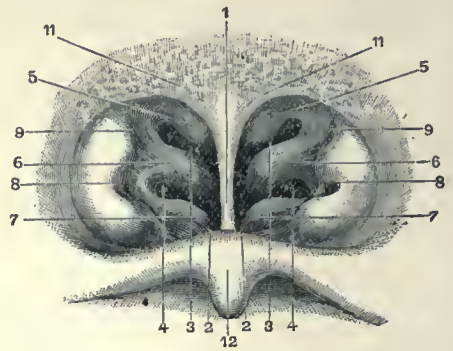
If, then, we keep a clear understanding of the anatomy of the mucous membrane lining the nasal cavities, the conditions found in hypertrophic disease are readily understood.

In examining cases of long-standing nasal catarrh, we are almost certain to find hypertrophic changes most clearly defined in those portions where the erectile tissue is most abundant—over the turbinated bones and the vomer.

It is my purpose to limit these observations to that portion of the nasal tract visible in the rhinoscopic mirror, viz., the posterior nares.

If we examine the image of a normal posterior naris, as seen in the rhinoscopic mirror, we will observe a picture somewhat resembling Fig. 1.

FIG. 1.[1]

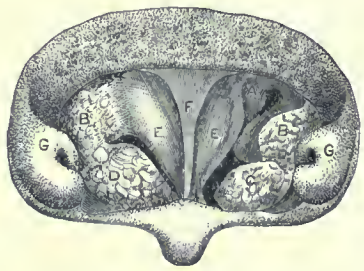


Rhinoscopic image of normal posterior nares. (Seiler.)

1. Vomer. 2. Free nasal passage. 3. Superior meatus. 4. Middle meatus. 5. Superior turbinated bone. 6 Middle turbinated bone. 7. Inferior turbinated bone. 8. Orifice of Eustachian tube.

In these openings are seen the posterior ends of the lower and middle turbinated bones, slightly scrolled and slanting, with their mucous covering; occasionally we get a view of a portion of the superior turbinated bone. Dividing these two openings we see the posterior portion of the vomer, wedge-shaped, with clearly defined surface gradually tapering to a narrow edge, as it joins the floor of the nose. Considerable spaces are observed between these turbinated bones, and between them and the vomer.

FIG. 2.



A. Superior turbinated bone (normal). B B. Hypertrophied tissue over middle turbinated bones. C D. Hypertrophied tissue over lower turbinated bones. E E. Hypertrophied tissue over vomer. F. Free surface of vomer. G G. Eustachian tubes.

If we now contrast this picture of the normal posterior nares with one such as is sometimes observed in cases of long-standing nasal discharge, a marked change will be noticed.

[1] This cut was kindly loaned by Dr. Seiler, taken from the second edition of his Handbook.

Fig. 2 illustrates what is often seen in the rhinoscopic mirror in a case of nasal catarrh of long duration.

CASE I.—The patient from whom this drawing was taken was a man twenty-six years of age, of good parentage and of fair health. His history showed that he had always been easily affected by atmospheric changes, and that the nasal tract suffered most from these changes. For twelve years he remembered having a discharge from his nostrils, which, however, gave him but little concern. During the summer solstice the discharge was much lessened. Respiration had always been good, according to his statement, and at no time was mouth-breathing necessary; no attacks of asthma had ever occurred. For some years constant efforts to clear his throat have annoyed him. The post-nasal discharge was greatest when he became excited, and during the early part of the day. The secretion from the posterior nares was viscid and difficult of removal. Rhinoscopic examination revealed the conditions as seen in Fig. 2. Enormous hypertrophy of the soft tissues over the vomer on each side, extending its entire length; much greater above than below. The posterior end of the lower turbinated bone greatly hypertrophied on the right side, less on the left side; diffused thickening of the posterior end of the middle turbinated bone on right side. An hypertrophy resembling a collar projecting from the outer wall of left posterior opening, on a line with the middle turbinated bone, and springing from its outer portion. It will be noticed that on the right side, the spaces belonging to the posterior opening are so encroached upon by the hypertrophies that nothing but a mere fissure remains unoccupied; so that, practically, the right posterior naris is occluded, and can afford but little facility for the passage of atmospheric air during

FIG. 3.

A. Hypertrophied tissue over superior turbinated bone. B. Hypertrophied tissue over middle turbinated bone (left). C D. Hypertrophied tissue over lower turbinated bones. E. Hypertrophied tissue over vomer, left side. F. Enormous swelling of the free surface of the vomer. G G. Eustachian tubes. Right middle turbinated bone shows diffused thickening.

respiration. The left opening is less encroached upon, sufficient air appearing to pass through for respiratory purposes.

CASE II.—Is faithfully represented in the drawing, Fig. 3, which shows the same hypertrophic changes, with modifications, as are seen in Case I.

A. H. L., æt. 36, native, married, has enjoyed remarkably good health all his life; belongs to a

wonderfully hardy stock, his father having died at a great age.

Fifteen years ago he first contracted an acute coryza, while exposed to very inclement weather. This coryza, which was severe in its onset, continued without abatement for fourteen years.

From the beginning of the attack he gradually grew worse, until, after years of annoyance, he was compelled to seek relief for the persistent and profuse nasal discharge. After many months of treatment, with but little mitigation of his disease, he abandoned all further medication, and resigned himself to his condition. For a number of years he endured his misfortune, continuing to grow worse. In the winter of 1881, he was compelled again to seek medical advice, when he came under my care. His condition was as follows: Profuse serous discharge[1] from both nostrils, which required the use of *five dozen* large handkerchiefs per week; the almost constant use of handkerchiefs was necessary, so persistent and so profuse was the discharge. Respiration was entirely obstructed on the left side; the right side allowed a small quantity of air to pass through it, but not sufficient for respiration, which had to be carried on through the mouth. Extraordinary attacks of sneezing[2] often supervened, lasting for hours. These attacks of sneezing left him exhausted, and frequently occupied hours which were necessary for rest. In addition to this his nights were broken by repeated attacks of asthma, rendering it necessary for him to seek an open window for freer respiration. Attacks of intense itching in the ear occasionally occurred. Thick tenacious mucus escaped from his post-nasal cavity, causing gagging, with oft-repeated hawking to dislodge it.

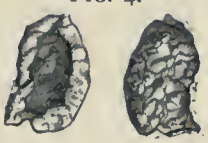
His voice was flat and nasal in character. With such a combination of distressing symptoms the patient's condition was deplorable.

Rhinoscopic examination was rendered extremely difficult, by reason of great irritability of the fauces, and the soft palate was unmanageable from the patient's inability to breathe through the nose. After repeated efforts had been made, and an unlimited amount of patience had been expended, a satisfactory view of the posterior nares was obtained.

The appearance was unique in several particulars; marked hypertrophic conditions of the soft tissues over *all* the turbinated bones of the left side were seen; the same conditions were present on the right side over the lower and middle turbinated bones. The vomer was greatly hypertrophied on the left side. A most peculiar condition of the vomer was manifest, which I have never seen in any other case. In place of the wedge-shaped vomer, with the hypertrophy some distance within its free margin (as is seen in Fig. 2, and as is usually noticed), there was an entire change in the shape of the vomer, its normal outline being lost in an enormous infiltration, which extended upon all sides; the lower portion, where it joins the floor of the nose, was increased so much that it appeared of the same breadth as above, while the infiltration was flush with the free surface of the vomer. This swollen tissue was regarded as an infiltration or congestion, caused from obstructed circulation, which was produced by pressure of the hypertrophies conjoined with the effect of an ever-existing rarefaction in the post-nasal space. Another most remarkable condition present in this case was an undoubted hypertrophy of the *superior* turbinated bone on the left side. The possibility of such a condition has been denied by very excellent observers, and to me was of so great interest that I made repeated examinations, lest an error in observation should occur. That this condition was present is indisputable. It is faithfully given in the illustration (Fig. 3).

The treatment of these two cases was in the main alike. As has been shown, the same pathological conditions existed in both. The treatment was essentially *surgical*. In my judgment, *successful* treatment in hypertrophic nasal catarrh can be no other than *surgical*. Whatever treatment of a non-surgical character may be instituted, it can be considered as but an adjunct, and secondary to the demands of these cases. I believe that treatment consisting of the usual medicinal remedies, applied in whatever manner elected, is futile for the *cure* of hypertrophic catarrh, and does, at best, but temporarily relieve the distressing symptoms of cases where the hypertrophic change has progressed but little. But in cases of marked degree, even where respiration can be normally carried on through the nose, any other method than prompt removal of all this redundant tissue is an illogical and irrational procedure. The treatment carried out can be well illustrated by way of example (Case II., Fig. 3). The nose in this case was extremely sensitive, and intolerant of manipulation. At each sitting, every attempt for many times was rendered but partially successful on account of prolonged attacks of sneezing, very often brought about by the introduction of the nasal speculum. All instrumental manipulation had to be done with the greatest delicacy and rapidity. As soon as an attack of sneezing supervened, all work for that time had to be suspended. After repeated sittings, the lower hypertrophy on the right side was engaged in the loop of Jarvis' snare and removed. This gave considerable relief to respiration on that side. The left side offered prolonged resistance posteriorly to the introduction of the snare, because of the impaction

Fig. 4.



of the hypertrophies in that orifice. After many fruitless endeavors, a passage for the wire loop was made, and the middle hypertrophy was removed, then the one over the vomer, then the lower one. Fig. 4 shows two views of the hypertrophy after removal from the lower turbinated bone.

[1] The serous discharge was greatly augmented by the presence of nasal polypi anteriorly.

[2] Partly dependent on the nasal polypi.

This made a marked change of the infiltrated vomer, which rapidly regained its normal shape and outline. As soon as the obstruction to the circulation had been relieved (by the removal of the hypertrophies), the hypertrophy on the superior bone decreased in size, and did not require any interference with the snare. After the removal of all these obstructions, the breathing through the nose became free, mouth breathing was no longer required; the attacks of sneezing subsided, and asthmatic seizures were banished. His voice became resonant and normal. After the snare had done its work, the galvano-cautery was employed to remove what general hypertrophic condition remained, to which the snare was not applicable. The amount of discharge gradually grew less during treatment, and finally became so little that a handkerchief was no longer a necessity. In cases of so marked degree as the above, I know of no method of treatment which would give such good results as were obtained in these cases by the use of Jarvis' snare, and the galvano-cautery.

The successful management of cases of hypertrophy of the tissues over the vomer *posteriorly* has always been considered difficult, because of the situation; but in the galvano-cautery we have a remedy which renders the treatment easy and successful, and all other procedures appear cumbersome and inefficient in comparison. In a few sittings a marked hypertrophy of the vomer, and the train of unpleasant symptoms attached to this condition, can be made to disappear. In my experience, no ill-effect has ever occurred. I have yet the first untoward complication to report.

To avoid secondary disturbances there are certain requisites, viz.: 1. A battery in perfect condition. 2. A very thin cautery knife. 3. Perfect adjustment to the part to be destroyed. 4. Contact of but a few seconds. 5. Thorough application of an antiseptic fluid to the parts cauterized.

LITHOTOMY AND LITHOTRITY IN THE MEDICAL MISSIONARY SOCIETY'S HOSPITAL, CANTON, CHINA, IN 1882.

BY J. G. KERR, M.D.,
OF CANTON, CHINA.

THE annexed tables present, in as condensed a form as possible, the operations for urinary calculus performed during one year.

Lithotomy in the Medical Missionary Society's Hospital, Canton, China, in 1882.

No.	Age.	Residence.	Occupation.	Duration.	Date of Operation.	Chemical Composition.	Diameter. In. In.	Weight. Oz. Dr. Sc.	Result.	Remarks.

It is to be remarked that in the population which furnishes these cases, bad hygienic conditions prevail, as is indicated by the fact that every boy operated on had to be treated for worms previous to the operation.

The season has not been a healthy one. Cholera, and a malignant form of fever prevailed during the autumn months; a few cases of both forms of disease occurred in the wards of the hospital. The fever, however, has not been violent in the city, but in some country districts it has been very fatal.

Chinese physicians never attempt to detect the presence of a calculus by sounding; and they have no instrument, either catheter or sound, by which it might be done. All the cases must therefore come to this hospital for the first examination, except a few who meet with pupils that have had some training here. Many patients spend years of suffering, before they know the nature of their disease, or of the existence of the hospital, where relief can be obtained. Large stones and all manner of complications are therefore met with, and many of them are not desirable cases to deal with.

Preparatory treatment is indispensable in most cases, and it is especially necessary to make a change of diet. The usual food of the country people is fish, fresh and salted; with salted vegetables. For this fresh meat, eggs and fresh vegetables are substituted, the staple food, rice, being allowed. With this regulation of the diet, and an occasional purgative or laxative, the digestive functions are got into healthy action, and if possible, all cystitis removed. Under such conditions, and with no complication in other organs, an operation for stone should always be successful.

In reference to the choice of operation, the lateral is performed in nearly all the cases of lithotomy. The median section has been used in two or three cases, where the stone was small, or where it became necessary to cut after crushing. The bilateral has been used in only one case, No. 39, because of the unusual size of the stone. The particular form of the incision, has in my opinion very little to do with the result of the operation; other factors combining to decide the fate of the patient.

Lithotrity is preferred in suitable cases, and in such as for some reason the knife is excluded. The Chinese are physically a smaller race than Europeans, and the urethra is too small in many cases, especially for Bigelow's evacuating tubes. These have been used in several cases with satisfactory results, but in the former part of the year the apparatus was not in working order. In one case with albuminous urine lithotrity was successful, when the use of the knife would doubtless have been fatal.

In most of the cases there was nothing worthy of remark but a few had features of interest, which may be mentioned. In eight of the lithotomy cases multiple calculi were found, the number being two in each of seven cases. No. 31 was remarkable in having one stone in the cavity of the bladder and thirty calculi in a sac. The sac was located just below the neck of the bladder, behind the prostate, and the incision opened into it. Examination per rectum gave the impression of one large stone, as was anticipated from the long period (20 years) during which the patient had suffered. The calculi varied in size from a bean to that of a chestnut, and were angular, with facets fitting accurately to each other, and as the sac fitted closely around them there could have been but very little motion. After the removal of all the calculi from the sac the single round stone was found in the cavity of the bladder.

One of the boys operated on was found, after being chloroformed, to have a urethra so small that no staff at hand would enter. A small sound was introduced, the incision in the perineum made down to it, and a grooved director passed into the bladder, on which the incision was completed.

In several of the cases severe hemorrhage followed lithotomy. For many years I have employed a tampon in the rectum as the means to control hem-

orrhage, and, in nearly every case, with satisfactory results. Sometimes it is necessary to give manual assistance for a few hours by pressing the tampon against the os pubis, and thus more effectually closing the track of the wound. From six to eighteen hours is long enough to let the tampon remain. The centre of a square piece of cloth, well oiled, is pressed into the anus, and a roller bandage put in gradually until a sufficient amount of pressure is made on the wound. An anodyne may or may not be required to allay tenesmus.

The last case given in the lithotomy list, but not numbered, was a man whose perineum and scrotum were burrowed with urinary fistulæ, in one of which the stone had formed. He also had a calculus in the bladder, but was too weak to undergo the operation. This is the second case in which I have taken stone from urinary fistulæ.

Lithotomy case No. 26 was a female, and is only the third case in about 850 operated on in this hospital. During the year another woman was admitted in whom a calculus was detected, but she was not willing to submit to an operation.

The whole number of cases of urinary calculus under treatment during 1882 was 104. Of these 12 remained in the wards at the end of the year; 2 died before operation, and the remainder either declined to be operated on, or were unfit for an operation, or deferred it to another time.

In the following tables, *C* and *D*, the cases are arranged as to age in decennial periods.

[I am happy to be able to present the preceding record of Dr. Kerr's cases, which came to me by letter in answer to an oft-repeated request. Any one who knows the amount of labor done by Dr. Kerr in the Canton Hospital and dispensaries every year, will understand why he so seldom contributes anything for publication, beyond what is prepared for his annual reports. Few operators have removed as many stones from the human bladder as he, and his success has been such, as to encourage him very much in operating upon the Chinese, not only for the removal of calculi, but of morbid growths of a much more serious nature.

Dr. Kerr has now performed lithotomy 449 times, and lithotrity upon 168 patients; making 617 cases from whom he has removed vesical calculi. The late Dr. Fun Wong, his native assistant, operated upon 34 cases: and Rev. Dr. Peter Parker, during his term of service, prior to that of Dr. Kerr, performed lithotomy 37 times. Besides these, there were many cases of removal of urethral calculi; and an almost incredible number of stones have been removed from beneath the prepuce, and constitute a collection unequalled in the world.

Some of the calculi removed by lithotomy in the Canton Hospital, were so large that they required first to be broken before extraction. Dr. Kerr removed one of 6 oz. 1 dr. from a man of forty-three; another of 5 oz., measuring 3 by 2 inches, from one of twenty-eight; and two stones 2¾ and 2 inches, and 2⅜ by 1¾, weighing together, 8 ounces, from one of thirty; all of whom recovered. Dr. Wong removed one of 3 by 2 inches, weighing 4 oz. 5 dr.: patient recovered. Some of the largest calculi have been very long and irregular in shape; others quite symmetrical and oviform. Occasionally patients have died in the hospital from cystic disease produced by a large calculus long existing in the bladder, having entered in a condition making an operation impossible. Dr. Parker removed a calculus from a patient after death, which was 3½ by 2 inches, very curiously irregular in shape, and bound down by adhesions. The man was twenty-one; had had the disease seven or eight years, and died on May 18, 1850. Dr. Parker was in charge of the work of the Medical Missionary Society for seventeen years, and Dr. Kerr succeeded him in May, 1855. With the exception of about three years, he has been in active work in China since this date. As a surgeon, his experience has been great and varied, and could be made of much value to the profession, had he the time to publish some of his rare and remarkable cases.

Dr. Whitney, of Foochow, writes me that he has a class of five Chinese medical students, and Dr. Dudgeon, of Pekin, is publishing Kirke's *Physiology*, in the classical Chinese.—R. P. Harris.]

MEDICAL PROGRESS.

Three Cases of Gastrostomy for Carcinomatous Stricture of the Œsophagus.—A. Knie (*St. Petersburger med. Woch.*, 1883, No. 2) reports three cases in which an early operation was performed with complete success, although one case died thirty-six hours after the opening of the stomach from perforation of the carcinoma into the left bronchus. In the other two cases the patients recovered rapidly after the operation and increased in weight, although before they had been steadily loosing weight under nourishment by the rectum. One case carried on his ordinary work for six months after the operation, and then, after paralysis of his left arm, died eight months after the operation; the other case was still living one month after the operation. No obturator was employed in the fistula, a simple drainage-tube with stop-cock being used; no eczema or escape of fluid was noticed.—*Centralb. f. Chirurg.*, March 10, 1883.

Resorcin in Simple Chancre in Females.—M.M. Lebland and Fissiaux give the details of six cases treated with resorcin (metadioxy-benzine). It is a solid, colorless body, with feebly aromatic odor, and

sweet, slightly bitter taste. Its solubility in water is 86: 100; also soluble in alcohol, ether, and glycerine. Exposure to light gives it a reddish-brown color. It coagulates solutions of albumen, and preserves them. It arrests fermentation and putrefaction in a remarkable manner. In solution of .50–1 to 100 it arrests the development of microphytes and microzoaires, and kills them. The adult easily takes 3j–3jss in twenty-four hours. It is eliminated by the kidneys. It seems to be indicated in all cases in which carbolic acid is employed. In the cases referred to, the chancre was brushed over with a solution of resorcin, varying from a weak to a saturated ethereal solution. Rapid recovery resulted; two cases in twenty days, one in nineteen, two in twenty-six days, and one in twenty-seven. Resorcin, though as rapid a *cicatrisant* as iodoform, has none of its inconveniences.—*Ann. de Gynecol.*, Jan. 1883.

Explication of Metalloscopic Phenomena.—M. Burg has made an ingenious apparatus which enables us to record the successive modifications impressed upon the nervous system by metallic application. It consists of a scale, on which is a needle; above are written the normal sensibility and motility; below, anæsthesia and paresia; on each side, analgesia and amyasthenia. The spring which moves the needle is the nervous system. By the aid of his apparatus, M. Burg explains the phenomenon called *transfert*. This *transfert* he regards as the simple phenomenon of *balancement;* not that he wishes to create a new word, but because he thinks that the word expresses the idea better than *transfert*, which is doubly inconvenient, as implying an idea forced and difficult to believe—*à priori*, that metallic applications are useless in treatment.—*Le Progrès Méd.*, March 10, 1883.

Paralysis from Injections of Ether.—Dr. Arnozan has seen four cases in which paralysis followed deep subcutaneous injections of ether, and concludes: 1. That injection of ether into the muscles causes paralysis. 2. These paralyses are analagous to peripheric paralysis. They cause suppression or diminution of faradic excitability. 3. They pass away spontaneously, but very slowly.—*Revue de Thérap.*, March 15, 1883.

Gangrene of the Female Genital Organs in Typhus.—Petrone (*Ann. Univ. di Med. e Chirur.*, 1882, Hft. 11) gives the details of some cases, with reflections on the pathogenesis of this affection. In two cases it began with vulvar diphtheritis; in another with inflammation of Bartholini's glands and abscess formation. In Petrone's collected cases, the trouble appeared between the fifteenth and twenty-eighth day. In some the trouble was confined to the labia majora; in others, the vagina, or even the uterus, was affected. When the latter, two-thirds of the cases were fatal. In the remaining, there were narrowing or occlusion of the vagina, recto-vaginal fistulæ, etc. The treatment consists in the most scrupulous antiseptic precautions, tonics, nutritive food, etc.—*Centralbl. f. klin. Med.*, February 24, 1883.

Treatment of Granulations of the Conjunctiva and Cornea by Purulent Inoculation.—M. F. Terrier, having studied the pathological conditions of such treatment, after indicating the dangers, draws the following conclusions: 1. Inoculation is a good method for treating old conjunctival granulations with pannus. 2. It is indicated in complete, thick, pannus, ulcerations of the cornea; incomplete or wasting pannus contra-indicates inoculation. 3. It is justified in monocular pannus, granular or not. Inoculation must be made with pus of ophthalmia of new-born infants. 5. The ophthalmia produced should be healed methodically, injuries to the edges of the cornea being avoided. 6. Rational treatment, such as cauterizing with sulphate of copper or nitrate of silver, pomades of precipitated yellow oxide of mercury, insufflation of calomel powder, etc., is frequently necessary. 7. Exceptionally a new peritomy or iridectomy is indicated.—*Revue de Chirur.*, February 10, 1883.

Anthropometric Study from the Point of View of Fitness for Military Service.—Dr. Jansen reaches the following conclusions in regard to the expansion of the chest:

1. The weight of the body and the degree of expansion of the chest give the precise indications as to the state of vital resistance and aptitude for military service.

2. The thoracic circumference, taken between the two inspirations, gives no indication of real value.

3. The measurement of the chest should be taken above the nipples.

4. After having noted the chest measurement during the repose following a respiration, the tape should be kept around the chest, and a deep inspiration should be made; the difference in the measurements shows the amount of expansion.

5. The following may be given as means: Men fit for service; weight, 142 lbs.; weight, by half measure of height, about 14 oz.; chest measure, 34 inches; degree of expansibility, 1½ to 2 inches. Men unfit for service: weight, 112 lbs.; weight by half measure of height about 10 oz.; chest measure, 32 inches; degree of expansibility, less than one inch.

6. In many cases, men whose chest measure is less than half the height are perfectly suitable for service, and frequently men with large chests are unable to stand the fatigues of military service.

7. There is a constant relation between the bodily weight, the expansibility of the chest, and the height, but none between these and the chest measure.

8. Sailors, boatmen, blacksmiths, carpenters, and cultivators are most robust; weavers and colliers least robust.

10. Five feet one inch may be taken as the minimum height.

11. Recruits of good constitution had a mean weight of about 10 oz. by half measure of height; the degree of expansibility of their chests averaged one and one-fifth inch. The chest measure was not always half the stature, but never fell below 30 inches.

12. Militiamen of bad complexion cannot stand the fatigues of military service.—*Revue Internat. des Sciences*, February 15, 1883.

Extract of Guachamaca.—The *Guachamaca* is a tree growing in Venezuela; the active principle is contained in the bark and other parts of the tree. The extract, brown, resinous, resembling curare, is soluble in water, less so in absolute alcohol, and insoluble in ether and chloroform. The chief difference between its action and that of curare is, according to Schiffer (*Deutsche Med. Wochens.*, 1882, No. 28), that guachamaca rapidly affects the nerve centres, while that action of curare is slow. Schiffer's experiments on man have been few, and he has always administered it subcutaneously. In a case of spasmodic muscular contraction, he injected gr. ½ of the dry extract. In forty-five minutes a light sleep was produced, which lasted about three hours; the circulation and respiration remained normal, and reflex excitability was preserved during the sleep. Schiffer thinks that it may be used advantageously in convulsive disease, and that it will prove a useful hypnotic.—*Le Progrès Méd.*, March 17, 1883.

CAUSE OF THE FIRST SOUND OF THE HEART.—DR. SPIRIDION KANELLIS (of Athens) has brought out a new theory of the production of the first sound of the heart, according to which the sole causes are: 1. The vibration of the tendinous cords and the friction produced by the blood; which, after a sufficiently great pressure, makes a noisy irruption through the network formed by these cords during the ventricular contraction. 2. The friction of the blood against the inequalities of the ventricular wall, which is at that moment contracted. This sound, says Dr. Kanellis, lasts until the ventricular systole.—*Revue Scientifique*, March 17, 1883.

ANÆSTHESIA BY GALVANIZATION OF THE SUPERIOR LARYNGEAL.—M. BROWN-SÉQUARD has shown that carbonic acid placed in contact with the laryngeal mucous membrane produces anæsthesia by excitation of the terminal filaments of the superior laryngeal nerve. Galvanization of the nerve-trunk itself generally produces only a slight diminution of sensibility; but in some recent experiments made on the dog, he has produced complete anæsthesia by this means.—*Le Progrès Méd.*, March 10, 1883.

NEPHRECTOMY.—Professor D' Autona, of Naples, on the 28th of December, 1882, successfully extirpated a pyonephritic kidney by the lumbar incision.

IODOFORM IN ITALY.—Semmola, Rummo, Ciaramelli, and Bufalini have prescribed iodoform in chronic affections of the respiratory passages. Semmola administers the drug by the stomach, believing that it is eliminated by the mucous membrane of the respiratory tract, as proved by the fact that the fever diminishes, and the cough becomes less fatiguing. Rummo employs iodoform in the form of a vapor by inhalation, and in spirit of turpentine in a four per cent. solution; he believes that the turpentine reduces the irritating properties of the iodoform. He claims that the cough and expectoration are reduced, the râles become less numerous, and the general condition improves.—*Gazette Médicale de Paris*, Feb. 24, 1883.

NEW FORMATION OF ARTICULAR HEADS OF BONES AFTER SUBCAPSULAR PERIOSTEAL RESECTIONS.—DR. BAJARDI has made a series of experiments on dogs three months old, always choosing as the region for his experiments the lower extremity of the femur. The results obtained by him differ in some respects from those obtained by Wagner and Ollier, but confirm the results arrived at from resections of human bones made by Lüelle, Doutrelepont, Heinemann, Czerny, Weichselbann, and Jagetho. Dr. Bajardi arrived at the following conclusions: 1. Resection of an articular extremity of a bone, practised on a young animal, is followed by an exact reproduction of the part, provided that the periosteum and articular capsule be kept intact, according to Larghe's method. 2. The articular extremity thus produced is composed of spongy tissue, and a greater or less extent of its surface is covered with an investing cartilage. 3. The bony and cartilaginous portions of the new articular extremity are developed partly from the diaphysis, partly from the marrow, and to a limited extent from the connective tissue which covers almost the whole of the bony portion of the excised epiphysis. 4. The new formation begins primarily in the marrow, in the form of embryonic connective tissue, which becomes rapidly transformed into cartilaginous and osseous tissue. 5. The periosteum of the diaphysis, and the connective tissue which covers the osseous portion of the apophysis, do not take part in the process of development until a later period. 6. The articular surfaces of the tibia and patella, when left intact, may or may not be very considerably modified, according to the reëstablishment, or not, of the original conditions of movement and reciprocal pressure. 7. These modifications consist in proliferation of the upper layer of cartilage cells, consequent on the peripheral cells becoming atrophied; in dissociation of the ground-substance (fibrous tissue), consequent on cellular proliferation and atrophy; and in transformation of cartilaginous tissue into fibrous tissue. 8. These modifications always commence in the superficial strata of the investing cartilage, and more or less slowly reach the lower or deeper strata.—*British Med. Journal*, March 17, 1883.

EXTIRPATION OF THE LARYNX.—G. BENDAUDI reports the case of a boy, aged 10 years, in whom Riggi opened the larynx in the median line with the galvanocaustic knife, intending to remove a large polypoid growth. On account of profuse hemorrhage from the tumor, extirpation of the entire larynx was resolved upon, which was successfully performed with a galvanocautery knife without hemorrhage. The edges of the œsophagus were sewed into the wound, and an ordinary tracheal canula inserted; a sound was permanently left in the œsophagus. The case progressed without any febrile reaction and the wound was completely healed in 28 days, without any deformity of the neck; deglutition was not interfered with.—*Centralb. f. Chirurg.*, November 11, 1882.

INJECTIONS OF CARBOLIC ACID IN SCIATICA.—M. SCHRUMPF has communicated the following to the *Société Médicale du Haut-Rhein* (June 11, 1882): Carbolic acid introduced into the cellular tissue in strong solution produces disorganization or suppuration. In weaker solutions, however, of one to three per cent., if the quantity injected does not exceed gr. iss, no accident will result; on the contrary, this treatment is not only palliative, but curative. The injection is soothing; in this respect being distinguished from those for which Luton sought to substitute simple water, morphine, chloroform, ether, alcohol, salt water, nitrate of silver, etc. As a rule, several injections are necessary to entirely relieve the pain. The usual quantity for injection is about one-third or one-half grain (the acid being dissolved in alcohol). Schrumpf has obtained excellent results in sciatica, lumbago, pleurodynia, coccygodynia, and cervico-brachial neuralgia. Idiopathic neuralgiæ alone seem favorably influenced by this treatment. Those caused by a medullary affection, or compression or an articular affection, or deep or superficial varices, are uninfluenced by these injections.—*Revue de Thérap.*, March 15, 1883.

PULMONARY SYPHILIS.—M. BRISSAUD has recently (*Le Progrès Médical*, No. 3, 1883) summed up our knowledge of this subject in a clear and concise manner. We may say at once that he deals only with acquired syphilis, and not with inherited. As in the case of the liver and other viscera, syphilis may give rise to two different lesions—one a fibroid change, mostly superficial, in fact, involving the pleura as much as the lung tissue proper; the other a gummatous change, almost always more or less deep seated, and often surrounding the large bronchi. These gummata are usually few in number, of firm consistence, a yellowish color, variable in size, somewhat drier than most morbid products. They are usually surrounded by a certain amount of fibroid change. The glands about the bronchi at the root of the lung become enlarged, caseate, and sometimes ulcerate into the bronchi. M. Brissaud is inclined to believe that this degeneration of the glands is, in the majority of in-

stances, the primary lesion rather than a specific inflammation of the lung, and he points out that the disease is most common in the immediate neighborhood of the root of the lung. As regards diagnosis, the chief difficulty, of course, is to distinguish between a syphilitic and a tubercular lesion. They are equally destructive; they give rise to analogous symptoms, either inflammatory or congestive. But they differ in the part affected, and this is the most important diagnostic point. It has often been said that hæmoptysis is less frequent and less copious in syphilitic than in tubercular lung affections; but this is not a sign upon which any reliance can be placed. A last point, and a very important one, is that when a person has died of a syphilitic affection of the lungs it is almost certain that other evidence of syphilis will be found either in the kidneys, the bones, or the skin. M. Brissaud thinks that the reason these affections are not better known is because they yield so readily to the proper treatment.—*Med. Times and Gazette*, March 24, 1883.

Capsular Incision in Reduction of Hip-joint Dislocation.—This case occurred in the service of Dr. Polaillon, at La Pitié. A dorsum ilii dislocation was diagnosticated. Four separate attempts at reduction were made, under chloroform. By the first, the head of the femur was thrown into the thyroid foramen, from which subsequent attempts at reduction proved unavailing. Muscular reduction could not be attained under profound chloroformization. On the forty-sixth day after the accident, Polaillon reduced it by incising the capsular ligament and breaking up the adhesions. Minute antiseptic precautions were carried out, including drainage. Death followed on December 20, 1882, four days after the operation. The patient was alcoholic. At the autopsy, the lungs were found congested at the base; heart fatty; liver enlarged, fatty, and suppurative; kidneys yellowish and fatty. The head of the femur was found in the cotyloid cavity; round ligament ruptured. This is the third operation reported of the kind. The first, by Volkmann, in 1876 (*Berlin. klin. Wochensch.*, No. 25, p. 357, 1877); the second, by MacCormac, in 1878. In both, the head of the femur was resected. Recovery in both. Volkmann made a longitudinal incision, which extended from the crest of the ilium to the great trochanter. MacCormac made a Y-shaped incision, including a large part of that region. Polaillon made his incision from the anterior-inferior iliac spine, extending down the axis of the thigh about four or five inches. He does not attribute the death of his patient to the operation, but to his alcoholism and general bad condition.—*Bull. Gén. de Thérap.*, March 15, 1883.

Influence of Electric Light on the Eyes.—Prof. Mauthner, in a communication to *Allgemein. Wien. Med. Zeitung*, No. 10, March 6, 1883, says that in estimating the influence of the electric light on the eyes, three factors must be considered: 1. The constancy of the light. 2. Its brightness and illuminating power. 3. The color. As to the first point, the electric arc gives an inconstant or unsteady light, and is therefore injurious to the eyes. The illuminating power is too intense, and is on that account injurious; and, finally, the color is not purely white, and on this account also it may prove injurious.

The Arrest of Hemorrhage.—About eight months ago M. G. Hayem established, by a series of experiments, that the vulnerability of the hæmatoblasts played an important part in the arrest of hemorrhage. These experiments, made on the living animal—dogs—have been more carefully repeated on the horse, with the result of confirming the former deductions. *En résumé*, he found that the blood-clot attached to the wall of a vessel is formed at its base; that is, at its point of insertion or origin, by an accumulation of innumerable hæmatoblasts. He considers this a further proof in favor of the *rôle* played by these elements in the formation of certain intravascular coagulations and of the relation existing between the integrity of the wall of the vessels and the fluidity of the blood.—*Revue Scientifique*, March 17, 1883.

Action of Thymol on the Circulation.—Dr. Fiori has noted the influence of thymol in doses of grs. vij–℈iv, on the temperature, pulse, respiratory movements, and arterial pressure in sixteen subjects. Observations were made every fifteen minutes. Thymol produces a rapid fall of the temperature, and a marked diminution of the pulse in fever. In health the pulse was slowed. The sphygmograph showed augmentation of the undulation of the curves. The blood-pressure diminished with the temperature. Thymol has no bad effect on the heart, and is, therefore, an important antipyretic.—*Gazette Hebdom.*, March 16, 1883.

Sudden Death in Gastric Ulcer.—Perforation of the stomach almost necessarily proves fatal by way of peritonitis, but in some instances death has been known to occur even more suddenly from the accident; that is, before inflammation has had time to be set up. Shock, hemorrhage, or suffocation has usually been accounted the immediate cause at work in this class of cases. Prof. Jurgensen has just described another and very remarkable mode by which gastric ulcer may suddenly prove fatal, namely, by entrance of the gaseous contents of the stomach into the circulation (*Deutsche Archiv für klin. Med.*, xxxi. page 441). A woman, aged forty-nine, suffering from severe symptoms of gastric ulcer, suddenly died, and within twenty-two hours the post-mortem examination was made, no appearance of decomposition being present in the body. A large ulcer was found on the posterior surface of the stomach, its floor being formed by the pancreas, and the splenic vein lay exposed and open. Manifestly as the result of this lesion, air was found in many of the bloodvessels, including the cervical, cardiac, and gastric veins, and the large trunks, and also in the cavities of the heart. Extreme interstitial and subserous emphysema could be traced from the seat of disease. *Prima facie*, there could be but little question of the source of the air and the cause of the sudden death; but to confirm his opinion, Prof. Jürgensen tried the experiment of injecting air into the femoral artery of one side in a dog, and watching the femoral vein of the opposite side. In a few minutes bubbles made their appearance, having traversed, therefore, both the peripheral and the pulmonary capillaries.—*Medical Times and Gazette*, March 10, 1883.

The Development and Growth of Nerves.—M. Vignal has given the following as the result of his researches, in a paper read before the Society of Biology: 1. The nerves are developed from the centre to the periphery, in the form of fasciæ, fine fibrillæ, and granulations ranged in order, and immersed in a homogeneous material. The periphery of these fasciæ is covered by embryonic connective cells; later, by a process of proliferation, these cells penetrate into the interior of the nerve fasciæ, and multiply there, dividing the fibrilli into small bundles and cover them. At the same time they differ from the ordinary connective cells by the great length of their longitudinal diameter, as compared with their transverse diameter, and being applied to the surface of the bundles of fibrilli, and constituting a special envelope for shaping and weld-

ing them together. At this time the nerve-fibre is made up, in its essential parts, by the bundle of fibrilli surrounded by protoplasm, which, itself surrounded by an envelope, is the axis cylinder.

The myeline appears toward the end of the third month of intra-uterine life, under the form of a thin layer which envelops the axis cylinder; sometimes it does not appear in the whole length of the nerve-fibre, but in the form of balls more or less elongated. In the following months it gains in thickness, but parallel to this there is a development of the protoplasm, which often occupies much more space than the myeline. Towards the end of embryonic life, the fibres, with the exception of the protoplasm, have almost all the appearances of adult fibres. The development of the nerve-fibres is much more rapid near the centre than at the peripheral points.—*Le Progrès Méd.*, March 10, 1883.

Dupuytren's Enterotome.—Last October, a very stout woman was admitted into St. Bartholomew's Hospital, under the care of Mr. Willett, suffering from a strangulated ventral hernia, situated midway between the umbilicus and the pubes—a very unusual situation. The patient had delayed long before applying to the hospital; and, when herniotomy was performed, the gut was found to be gangrenous, and an artificial anus resulted. The condition of the woman was thus very serious, as the portion of bowel which had sloughed was a knuckle of the small intestine, probably rather high up. All feces passed by the artificial anus, and the woman steadily emaciated. After delaying long enough to preclude the hope of spontaneous cure, Mr. Willett determined to resort to Dupuytren's operation, which consists in applying a clamp of peculiar construction to the piece of intestinal wall, called by Dupuytren the *éperon* or spur, which intervenes between the upper and lower portions of gut at the artificial anus. After considerable delay, two enterotomes were procured from Paris; and one of these, a modification of Dupuytren's original instrument, was applied on February 23d. The patient experienced no pain or inconvenience, and the enterotome came away on March 1st, holding in its jaw a piece of shrivelled tissue. Up to the present time, no benefit has apparently resulted from the operation; but it is gratifying to find that the gloomy forebodings, with which the proposal to apply the enterotome was received by some, have not been fulfilled.—*British Medical Journal*, March 17, 1883.

Nutritive Suppositories.—Spencer (*Lo Sperimentale*) recommends that suppositories should be made of artificially digested meat, wax, and starch, in proportions necessary to obtain the desired consistence. When the rectum is very irritable, a small amount of opium may be added.—*Journ. de Méd. de Paris*, March 10, 1883.

The Technique of Resection of the Pylorus.—V. Wehr has made a series of experiments on dogs, under Rydygier's direction, with a view of perfecting the method of operation in resection of the pylorus. His recommendations, based on nineteen operations, are as follows: The most absolute antiseptic precautions must be observed; the stomach must be emptied as completely as possible before the operation; the omentum must be separated without loss of blood; escape of gastric and intestinal contents into the peritoneal cavity must be absolutely prevented; this is best accomplished by Rydygier's compresses; the stomach and intestine must be accurately reunited by three rows of close catgut sutures "furrier's round sewing." The cases require careful watching after the operation.—*Centralb. f. d. med. Wissen.*, March 10, 1883.

Nature of Phthisis in Diabetes.—Immermann and Rutimeyer have put on record (*Centralblatt für klin. Med.*, No. 8) a case which is of interest in connection with bacterial pathology. A patient, aged twenty-nine, was brought to the hospital in a state of profound coma and dyspnœa. The urine contained three per cent. of sugar and a trace of albumen. The man succumbed in nine hours. At the post-mortem examination, a vomica in the apex of the right lung with caseation was detected. The contents of the cavity yielded bacilli, which behaved to staining-fluids just as those from tuberculous cases do. Death was attributed to diabetic coma. In a footnote, Leyden (one of the editors of the *Centralblatt*) states that he has discovered the tubercle bacilli in the sputa in three cases of diabetes complicated with phthisis. The authors speculate on the identity of the pathological process in the lungs of ordinary phthisis and in those of diabetes. The frequency of consumption in diabetes is thought to be explained by the hypothesis that the diabetic constitution affords a specially favorable soil for the growth of the bacillus.—*Medical Times and Gazette*, March 10, 1883.

Solution of Ergotine for Hypodermatic Injections.—M. Dannecy, chief pharmacist to the hospital at Bordeaux, obtains a solution in the following manner, which he proposes as a substitute for that of Bonjean: he exhausts by displacement, with cold distilled water, the ergot-rye, suitably divided and cleared of its oil by washing with sulphide of carbon; the liquid remaining is evaporated to about one-third its volume and cooled. The albuminoid matters deposited are separated by filtration, and the resulting liquid is placed in contact with animal charcoal, well washed for twenty-four hours at a temperature of 76°–86° F. Then filtering again after cooling, washing the charcoal-charged filtrate with a sufficient quantity of distilled water, mixing the decolorized solution and the water of washing, the whole is evaporated over a water-bath to 90 parts for 100 of the ergot-rye employed, and 10 parts of cherry-laurel water are then added; after cooling, this is again filtered. The solution thus obtained is of an amber color, strongly reddens litmus paper, and contains, per gramme, the same quantity of the acid principle as one gramme of ergot-rye; by concentration over a water-bath the strength may be doubled or tripled. Numerous experiments have proved the activity and harmlessness of this solution.—*Bulletin Gén. de Thérap.*, March 15, 1883.

Ovariotomies in Italy.—Peruzzi reports that from July 15, 1880 to June 15, 1882, one hundred ovariotomies (completing the third hundred) were performed in Italy. Of these, 74 women recovered: 9 operations were not completed, of which 4 died. The supravaginal amputation of the uterus was done 27 times, with 7 recoveries.—*Centralblatt f. Gynäkol.*, March 3, 1883.

Treatment of Infantile Paralysis by Electricity.—Dr. Dive (*Thèse de Paris*, 1882), from very complete and interesting observations, concludes: 1. Continuous currents applied near the beginning of the disease, may cure. 2. Induced currents are efficacious later in the disease, and when the movements return in the paralyzed limbs. 3. The two forms of electricity combined and continued for a long time, produce the best results, especially in desperate cases.—*Bulletin Gén. de Thérapeutique*, March, 15, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.

SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, APRIL 7, 1883.

RECENT SANITARY LEGISLATION IN NEW JERSEY.

THE Legislature of New Jersey, which adjourned March 16th, enacted a number of laws of importance in the sanitary work of that State. In a supplement to the general law governing local boards of health, many additions were made to the powers heretofore conferred on these boards, among which we may mention the following:

Local boards of health formed under the State law shall be the only bodies having powers relating to public health matters; local boards may abate nuisances or sources of sickness without passing ordinances relating thereto; the rights of local boards to abate nuisances are founded on police or summary proceedings on account of the peril to the public health from such nuisances; the State Board of Health may appoint township physicians where now no such officer exists; local boards of health shall have the authority to specify any contagious disease in which no funeral shall be had, and shall prohibit such funerals under a penalty of $50.

An important section relating to the compulsory reporting of cases of contagious diseases was passed, giving local boards of health power to enforce the reporting of contagious and infectious diseases by the attending physician, and requiring a record to be kept by the board of all such reports, and at the end of each six months the reporting physician is entitled to collect from the local board twenty-five cents for each case.

This is the first instance on record where the labor of physicians in such cases is to be paid for, and will forever silence that portion of the profession which has objected to informing the authorities without compensation for services rendered.

The law regulating the practice of medicine was amended and made more stringent; the provisions of this law are as follows: No person shall commence or continue to practise medicine or surgery without first filing a copy of his diploma with the clerk of the county in which he shall practise. Any violation of this provision shall be deemed a misdemeanor, and upon conviction the person violating the law shall be fined $25, or imprisoned for a term not to exceed six months, or both, for each prescription made, operation performed, or professional service rendered. Any person who shall have had twenty years' practice in one locality, and who shall file with the county clerk an affidavit setting forth such facts, shall be exempt from the requirements of the law. The county clerk is required to keep a record, open to the public, of all copies of diplomas filed with him, and also to transmit a list of those registering to the State Board of Health. The State Board will, in its annual report, publish a list of all physicians entitled to protection under the law, and thus much good will be accomplished. The old law, quite similar but not so strict as this, was rigidly enforced last year in Essex, Passaic, and other counties, and kept not a few irregular practitioners out of the State.

The law prohibiting the sale of adulterated foods and drugs was amended and strengthened. The State Board of Health is to appoint analysts and inspectors to aid in its enforcement. An appropriation of $1000 was made to carry out the provisions of the law. This act contains a very unique provision, one not found in similar laws enacted in other States, or in the English or Canadian adulteration laws; it provides that if upon inspection of food or drugs the same shall be found to be adulterated, the health officer or inspector shall have power to forbid the sale of the article until decision is rendered by the court. This will certainly do much good in certain cases, and we await with interest the result of its enforcement.

The regular annual discussion and attack on the law to prevent the sale of impoverished milk took place, but resulted rather in a victory for the law. This law has proved of great benefit to the farmers in the northern and eastern part of the State, in that it has kept off the market large quantities of poor milk; it has also done good by reducing the quantity of poor milk sold in our cities.

The principal objection to the law seems to be that it was rigidly and impartially enforced. There is now in the hands of the Governor an act prohibiting the sale of skimmed milk in cities in the State, but we are not informed as to whether he will sign it or not.

The law to prevent the sale of dangerous illuminating oils, which did so much good last year, was perfected, and the test fixed at 100° Fahr., flash, instead of having both a flash and fire-test as formerly. The law now is similar to the New York statute.

One of the most important and philanthropic measures enacted by the Legislature was an act creating a State Council of Charities and Correction. This, although similar to the New York law in its purport, is not as sweeping in its requirements, as will be seen by the following of its provisions:

The Governor shall appoint six persons, who shall constitute a Council of State Charities and Correction, of which the Governor shall be president and an *ex-officio* member. The persons first appointed shall serve for one, two, three, four, five, and six years, respectively. This Council shall hold regular quarterly meetings at Trenton, and at such other places as may be deemed necessary.

The Council shall investigate the system of public charities and correction institutions of the State, and examine into the condition and management of all prisons, penitentiaries, jails, reform schools, etc., and of all State, county, town, and city lunatic asylums, hospitals, infirmaries, or other public institutions of charity or care, and of persons therein detained; and may recommend such changes and additional provisions as may be deemed necessary or desirable for the economical or efficient management of any one, or all of these institutions.

The members of this Council are to receive no compensation, except for actual travelling expenses and special services, and may appoint persons to aid them as inspectors; and shall send delegates to the meeting of the National Conference of Charities and Correction.

Persons in charge of all public institutions shall keep a record covering the following facts: name, age, sex, nationality, orphanage or half-orphanage, married or single, and other facts relating to the life, heredity, or history of the inmates; together with the cost of maintenance per day, amount earned by each inmate, hours of labor, etc.; and on the 1st of October, copies of these records must be sent to the Council. The Council will make an annual report to the Legislature. One thousand dollars was set apart to aid in the work of the Council. This law is a good starting-point, and cannot but be of benefit to humanity and society.

It cannot be said that the New Jersey Legislature has not been of late alive to public health interests in that State, and it certainly has done much good work, which will redound to the advantage of the Commonwealth and its citizens.

THE BACILLUS TUBERCULOSIS IN URINE.

THE acme of the bacillus wave which, since the publication of the researches of Koch, little more than a year ago, has been sweeping over the medical world, would seem to have been reached in the detection, in the urine, of the tubercle bacillus, by S. ROSENSTEIN, of Leyden (*Centralblatt für die medicin. Wissensch.*, Feb. 3). The fungus had been previously found, by Lichtheim, in the contents of the pelvis of the kidney of the dead body, but not in the living subject.

The patient was a man, thirty-seven years old, with good family history, who had himself always enjoyed good health until four years before coming under observation—when he first noted pain before and during urination. Two years later, he noted first in the right, and later in the left epididymis, a hardness as large as a small walnut, the testicles themselves being free. There was no lymphatic enlargement or disease of the lung; no fever. Micturition was frequent; the twenty-four hour's quantity between 800 and 1660 cc., and specific gravity 1012–1018. The urine was pale yellow, acid, turbid when passed, and highly albuminous; contained white flocculi as large as a pin's head, and deposited a sediment of pus and a little blood.

The urine was passed into a solution of thymol, and, after twenty-four hours, a drop of the sediment placed on a thin cover, dried over a gas-flame, treated according to Ehrlich's method, and studied with a Hartnack objective No. 3, eyepiece No. 9. Large numbers of bacilli were found in the white particles above referred to. Rosenstein claims, also, that they stain differently from the ordinary decomposition-bacteria found in the same urine.

No inference is drawn from these results. But it may be presumed that from them may be inferred tuberculosis of the epididymis. Here, indeed, is a practical application of rare value. In the case of the lungs, we have physical signs to aid us; but it is well known that we have nothing but guesswork to aid us in the diagnosis of tuberculosis of the urinary passages; and if we may infer from the bacillus thus found the existence of such disease, our difficulties are at end. We can only say, at present, that we fear it seems too good to be true.

THE ELECTRIC LIGHT IN SURGERY.

MEDICAL men, and especially surgeons, are constantly called upon to investigate the various tubes and closed cavities of the body, and when doing so have been defeated, usually, by the insufficient illumination. With Goethe, they have sighed for "*Mehr Licht.*" The problem seems to be on the eve of solution, if not indeed solved.

Apart from the mechanical obstacles, the difficulty has generally been to avoid the heat that

necessarily accompanies intense light. Leiter, the well-known instrument maker, of Vienna, with the aid of Mikulicz and others, has devised an apparatus, described by Dr. Roswell Park in the March number of the *Brooklyn Annals*, which is of sufficient importance to justify prominent mention. It consists of a battery, and connected with it, a number of instruments fitted for the examination of various organs. To obviate the heat, each instrument is in a double tube, and between the two there passes a constant stream of water. Windows are made both for the emission of the light and for observation, and, when necessary, a lens or a series of lenses deflect the light to the observer's eye. The dentist can operate by its aid as well by night as by day. The interior of the urethra and the bladder, the ear, the nose, the larynx, the rectum, the vagina, the uterus, and even the œsophagus and the stomach are all made accessible to observation. Leiter has photographed the larynx by its aid, and Park has seen the pylorus as clearly as the optic disk —red as the retina, and in constant peristalsis, alternately opening and closing. A point which excited considerable interest some years since, he does not allude to, viz., whether there is any such transparency of the abdominal walls that a light in the stomach, bladder, or other organ would aid us in the diagnosis of abdominal and other tumors. Up to last autumn, only three of these instruments were in this country, one each in New York, San Francisco, and Chicago. Our ingenious American surgeons and instrument makers ought to be able to improve materially, however, on these complicated and, we fear, rather too clumsy instruments for general use.

The article may also well point a moral in connection with our remarks on Medical Philology in our last issue. Not to speak of misprints, both of English, French, and German, or of the illegitimate word "diagnose," we must protest against the use of such admixtures of Latin and Greek as "vagino-scope" and "recto-scope." The first should be "elytroscope," and the latter "archoscope." One might as well speak of an "earscope" or an "auroscope" instead of an "otoscope." Moreover, the author in using the word "fenestrum" has evidently forgotten the fact that there is no such Latin word. The proper word is "fenestra."

THE BACILLUS TUBERCULOSIS IN THE DIAGNOSIS OF TUBERCULAR ULCER OF THE LARYNX.

B. Frænkel (*Berliner klinische Wochenschrift*, January 22, 1883) has sought to determine the value of the bacillus in the diagnosis of tubercular laryngitis. After quoting various specialists to the effect that it is impossible or extremely difficult to recognize the tubercular ulcer of the larynx by means of any features peculiar to itself, he says that for many years he has taught that in the majority of cases tuberculosis can be diagnosticated as such by the laryngoscopic picture. He still admits, however, that there are a certain number of cases in which such a diagnosis is impossible. In these cases we are compelled to look for other aids; and such are afforded by "Koch's brilliant discovery of the tubercle-bacilli." By the aid of the laryngoscope and a brush, small portions are removed from the tubercular ulcer. This operation is said to be easy, and probably is, in the hands of the expert, Frænkel having failed but once in sixteen cases. In three only of the fifteen remaining cases did he fail to find the bacillus, having taken at least three specimens from each. The ulcers in these three instances were syphilitic. In nine of the twelve remaining cases the bacilli were found at the first examination; in two at the second, and the remaining one in the third. He claims that we can by this method determine with absolute certainty the tubercular nature of a laryngeal ulcer; but that in order to do this it is necessary to examine at least three specimens of mucus thus obtained. When a negative result is obtained in three such instances, we need not hesitate to declare the ulcer non-tubercular, let the remaining symptoms be what they may. As the bacilli are also found in ulcers in the larynxes of phthisical cases in which microscopic examinations post-mortem fail to discover gray nodules, such ulcers must be regarded as tuberculous in their origin.

SANITARY INSPECTION OF SCHOOLS.

We have just received a copy of a bill amending Section 2,135 of the Revised Statutes of Ohio, so as to make the sanitary inspection of all schools in that commonwealth obligatory. The added clause is as follows: "And the said Board [of Health] is hereby required to inspect semi-annually, and oftener if in the judgment of the Board it shall be deemed necessary, the sanitary condition of all schools and school-buildings within the limits of the Corporation."

This bill contains, by implication, all the powers which were more explicitly expressed in a measure presented last winter, but which failed to pass. It applies to all schools, whether public, private, or parochial, and being thus a general measure, its advantages will soon be broadly tested.

Ohio is to be congratulated upon this progressive step, due to an enlightened public sentiment on the subject of health and education; and we commend the untiring efforts of Dr. Tuckerman and

his coadjutors in behalf of the results just accomplished.

The subject of the health of school-children is more than ever the theme of discussion, not only here, but in other lands. It has borne rich fruit in the city of Brussels, where an excellent system of sanitary inspection has already been established.

As recently as January last, before the Annual Congress held under the auspices of the Educational Institute of Scotland, at Aberdeen, Dr. Farquharson, M.P., in a forcible address exposed the evils prevalent in the national schools, by which the health of children of tender years is imperilled, and pointed out the remedies to be adopted. He strongly advocated the appointment of medical inspectors in schools, who should superintend the construction of all school-buildings, regulate their ventilation, proper heating and lighting, and who should also have some voice in deciding the amount of instruction suitable for different pupils. His views met with general approval at the Congress, and will ultimately lead to good results. It is to be hoped that this public discussion of the subject will be continued until a rational system of protecting the health of the young while being educated shall have been everywhere adopted.

A mortifying contrast is, however, presented to this action in the conduct of the same legislative body when a bill making vaccination compulsory was introduced by Mr. Ellsworth. "There was a pile of fun in the House," says a special Columbus (O.) newspaper correspondent, when the bill was introduced. "Motions to refer to the committees on ditches, drains, and water-courses, printing, and federal relations, were made and lost. One member moved that the bill be made local, and apply to Ellsworth and his constitutents; and another that it apply to persons over 100 years of age," while the bill was finally postponed indefinitely.

That a body of men elected, presumably on account of their intelligence, by the people to represent them in enacting laws for the public good, should treat in this manner any measure seriously proposed, whether it be expedient or not, is disgraceful to those taking part in the puerile exhibition, and humiliating to their intelligent constituents. Let us hope that the latter will mark the offenders, and discriminate accordingly at the next election.

TRANSITORY POST-EPILEPTOID PARALYSES.

In a careful discussion of this subject by M. Dutil, which appears in the *Revue de Médecine*, No. 3, 1883, we find some points which may be of interest to our readers. True epilepsy is rarely accompanied with paralysis; on the other hand, partial seizures and epileptiform attacks are not unfrequently so complicated. Epileptiform convulsions due to cortical lesions are frequently associated with permanent paralyses. Sometimes the paralysis precedes the epilepsy—in other words, a hemiplegic or monoplegic is attacked by convulsions of the epileptiform character. Sometimes, on the contrary, paralysis succeeds to the epileptic attack—partial convulsions are followed by transitory pareses, or paralyses. Post-epileptoid paralysis is usually situated in the muscles which are exclusively, or chiefly, involved in the convulsive seizure. In general, it may be affirmed that where permanent paralysis is followed by epileptiform attacks, the lesion is situated in the cortical motor zone. On the contrary, the partial seizures, not accompanied by permanent paralysis, are due to lesions in the neighborhood of, but not in, the motor area. The presence or absence of permanent paralysis becomes, then, a means of topographical diagnosis.

Transitory paralysis of some minutes, hours, or day's duration after the convulsion, does not indicate a destructive lesion of the motor convolutions. It is induced, perhaps, by an irritative lesion at a certain distance from the motor area, and, it may be, under the influence of a peripheric irritation.

It is obvious that M. Dutil adopts in their entirety the views promulgated from time to time by Dr. Hughlings Jackson regarding the cortical motor centres, the effect of peripheral irritation, and the essential difference between irritative and destructive lesions of the motor area.

THE SEWERAGE SYSTEM OF MEMPHIS, TENN.

In his report for the year 1882 Dr. G. B. Thornton, President of the Board of Health of Memphis, Tenn., remarks that it has been recently published by several widely circulated papers that the death-rate of Memphis has increased since the construction of the sewers, and is attributed to them. This, he contends, is an erroneous impression. The mortality of the city for the past two years exceeded that of 1880, but it must be remembered that the population also has increased.

The census of 1880 gave the city a population of 33,593, while recent estimations put the number at 46,014. Again, the increased mortality of 1881 as compared with the preceding year was not due to local causes, but to atmospheric influences, which caused a like high rate of mortality—mainly from diarrhœal diseases—in several localities in West Tennessee where there were no sewers.

The zymotic diseases which prevail so fatally in the impure atmosphere caused by sewer gas, such as diphtheria, scarlet fever, typhoid fever, etc., have contributed very little to the mortality of Memphis during the past three years. The total number of

deaths from diphtheria in these three years was 53, from scarlet fever 15, and from typhoid fever 45. These are considered low figures for three years in a population of 40,000. Dr. Thornton selected these three zymotic diseases for this period to prove the fallacy of the assertions of those who criticise the death-rate of Memphis so invidiously, and seem to attach so much importance to what they are pleased to attribute to the evil effects of the sewers

KOCH AND SPINA.

We have already called attention to the studies of Spina upon the so-called bacillus tuberculosis, as the result of which he feels justified in declaring the experiments of Koch defective, and his conclusions unwarranted. No other observer has so pointedly attacked the position of Koch, and in the face of the almost unanimous tendency of recently published opinions, Spina's results are nearly as startling as those of Koch, when announced just about a year ago.

For the present, we will simply invite the attention of our readers to the communication, in another column, of our Vienna correspondent, from which it appears that, whatever may be Spina's qualifications as a general histologist, he fails to display the skill in manipulative mycology which characterizes the labors of Koch. In a future issue we shall have something to say about Koch and his critics.

REVIEWS.

A Treatise on Fractures. By Lewis A. Stimson, M.D., Prof. of Surgical Pathology in Univ. of City of New York. 8vo. pp. xvi. 598. Philadelphia: H. C. Lea's Son & Co., 1883.

It is so long since a new American treatise on Fractures has appeared, that we welcome Dr. Stimson's with no little pleasure. It is an excellent guide to the profession, and will be cordially received by it. It shows wide reading and good judgment. At times it is somewhat unsatisfactory from want of explicit directions, *e. g.*, in the chapter on treatment as to the time when passive motion should be begun in various fractures. The index, too, is not so full as it ought to be. Moreover, the book has somewhat too much of a local flavor for a work intended to appeal to the wide constituency of the entire country.

The number of figures is much less than it seems to be, for very many of them do double duty. Some are carelessly done, as Figs. 91 and 298 show Nathan R. Smith's anterior wire splint suspended vertically, so that no extension is made on the broken femur, though Figs. 92 and 299 show Hodgen's splint, which acts on the same principle, with very marked extension. Figs. 113 and 293 (from Hamilton) surely show fracture of the wrong leg.

We are glad to see Fowler's "carrying function" of the arm recognized, as also Dr. Allis' important papers on fractures near the elbow, and that the use of plaster splints is heartily commended. The book is a valuable addition to our surgical literature

La Femme Stérile. Par le Dr. P. M. Dechaux, de Montluçon, Ancien interne des hôpitaux de Paris, Laureate de l'Institute, Médicin en Chef de l'Hôpitaul de Montluçon, Membre du Conseil d'hygiene et de Salubrité, etc.

The Sterile Woman. By Dr. P. M. Dechaux (Montluçon), Laureate of the Institute, etc. 18mo. pp. 212. Paris: J. B. Baillière et Fils, 1882.

A novel feature of this book, distinguishing it from all other medical books of which we have any knowledge, is a *lettre-préface* signed *une Grand'Mère*. Of all persons, we should select a "grandmother" as least likely to know any of sterility (from personal experience). She writes: "I believe that this little book will be of much interest to men generally, to naturalists, and to *grandmothers*." How it can interest the grandmothers we are at a loss to conjecture. But if the *lettre-préface* is a curiosity what shall we say of the author's preface, in which he apologizes for the use of technical terms, but says that the fault lies in his subject, and in the dictionary, which does not always furnish words sufficiently *converts*, and adds: "I certainly am for modesty in speech and action." He must be! We are reminded of the young lady who referred to a bull as a *gentleman cow*, though she did not go so far as to say that the fault lay in the sex of the animal.

As causes of sterility, the author mentions *vices of conformation, and uterine deviations and displacements*, but leucorrhœa he does not grant. On the contrary, he claims that this affection is normal to every woman between the age of puberty and the menopause. As a proof of this, he says it has been a common affection of women since the earliest times; that it plays an essential part in the organization and physiological functions of woman, because, as before mentioned, it is only present during the period from puberty to the menopause. A potent argument! True, he does recognize a degree of leucorrhœa which he calls *complicated*, arising from *manifest lesions*, functional troubles, and *general reactions*. And in speaking of the treatment *for complicated* leucorrhœa, he gives the speculum in particular and gynæcologists in general, such another blast as must surely deter all young practitioners from using such an instrument, or studying such a science, under pain of being ostracised.

Under a fourth set of causes given by authors, he mentions lymphatism, general feebleness, anæmia, chlorosis, nervous excitability, indifference, obesity, etc., but Chapter III. is commenced with the statement that of all causes, absence of the uterus is the only certain and admissible one. Chapter IV. treats of "Human Conception." But for this chapter, which contains a "discovery," we should not have thought it worth while to mention so remarkable a book. The author seems to have made a discovery regarding the exact manner in which the spermatozoa find their way into the cavity of the uterus. From all that we can gather, amid a volley of exclamation points, is the fact (?) that they *swim* into the uterus in the discharge, *la glaire uterine*, to which physicians have persisted in giving the name leucorrhœa, which they have persistently regarded as a morbid state, and which for so many years they have been vainly treating. "The common theory, the most seducing," says the author, "of intra-uterine injection of semen, is impossible because the uterus is always full, and because by mediocre forces one mucosity cannot displace another. To force a liquid into the uterus requires a syringe and a *surgical* force." We will merely say concerning this statement, that a case has been reported[1] of suicide

[1] American Journal of the Medical Sciences.

almost immediately after coition, in which semen was found in the cavity of the uterus and in the *Fallopian tubes*. If it was not *injected into* the uterus, how did it get there? We are willing to concede that in many cases there is scarcely a possibility of such intra-uterine injection, as, for example, where the hymen remains intact after coition so as to preclude the possibility of penetration, but it may be pertinent to ask M. Dechaux why animals are furnished with long penes. If it is only necessary to introduce the semen into the vagina, a penis of one or two inches would be as efficient as one of six. The author has concluded that fecundation is produced by the intermediation of the discharge, which gynæcologists and other *errorists* call leucorrhœa, which he, however, calls *une glaire*. With this beam of light thrown upon the hitherto mysterious secret of fecundation, he now proposes to revolutionize the medical world.

As a *consequence of his discovery*, he assures us that a woman is likely to become pregnant if she has intercourse. This information is simply invaluable to those who already have enough children in their families. It will only be necessary for them to abstain from intercourse hereafter, and no unwelcome children will make their appearance. To prove his theory of non-injection, he triumphantly relates the case of a woman who married with an unreduced prolapsed uterus and had no children for twenty years. This was conclusive evidence that the intra-uterine injection of semen was not capable of causing fecundation. Probably, the idea that a prolapse of the uterus was a sufficient cause of sterility has not yet occurred to him. We have not yet noticed one-half of this remarkable book. One chapter, VI., treats of Sterility as a Force; Chapter X. of Artificial Fecundation; Chapter XII. of the Philosophy of Sterility, etc. But it is useless to protract this notice. We will only say that no library of literary curiosities is complete without a copy of it.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, March 13, 1883.

THE PRESIDENT, T. M. MARKOE, M.D., IN THE CHAIR.

SUTURING OF THE DIVIDED ENDS OF EXTENSOR TENDONS IN THE FOREARM.

DR. F. LANGE presented a lady patient who, about two months ago, fell from a considerable height, and struck against a china umbrella-stand and cut the tendons of the extensor muscles of the left forearm. He saw the patient two weeks afterward, when the wound was almost healed and there was extensor paralysis involving the third and fourth fingers, only the last two joints moving through action of the interossei. About four weeks ago he made a longitudinal incision, and found that three of the extensor tendons had been divided; namely, those belonging to the third and fourth fingers and to the index finger. The extensor indicis was not injured, because the action of the index existed. The divided tendons of the extensors were separated to a distance of almost one inch and a half. They were brought together and sutured with antiseptic silk. The hand was then put in a position of hyper-extension, and an antiseptic dressing applied. The sutures were removed at the end of one week. The result was that the movements of the fingers could already be quite satisfactorily performed, and it was probable that improvement would still continue to increase.

SUPRA-CONDYLOID FRACTURE OF THE HUMERUS, WITH INJURY OF THE MEDIAN NERVE; OPERATION.

DR. LANGE also presented a girl, eight years of age, who, in August last, received a supra-condyloid fracture of the left humerus from a fall of three or four feet and striking the arm against a beam. A dressing was applied, which she bore for some time, and during the third week—according to the mother's statement—painful contraction of the fingers and wrist occurred. At that time forcible traction seems to have been made, but the pain did not cease, neither the contraction; but, on the contrary, the hand became more and more contracted and paralyzed, and finally quite useless. From the time of the receipt of the injury, she had complained of pain at the site of the fracture. She came to New York about the middle of December, at which time the wrist and fingers were flexed to their utmost, and the movements of the fingers were very slight, indeed; only slight movement of the first phalanges and of the wrist could be made. Every attempt to stretch the parts was followed by intense pain, especially at the site of the fracture, where there could be felt distinctly a sharp protruding edge of bone, and between the fragments there seemed to be a sensitive chord, which he thought might be the median nerve, but this subsequently proved to be an erroneous assumption. The movements in the elbow-joint were restricted to an angle of about twenty degrees. There was paralysis of sensibility in the region of the median and the radial nerves, and entire absence of electric irritability. Dr. Lange recommended at first electricity, massage, and active and passive movements. This treatment was administered for about six weeks, at first with some marked success; after several weeks, however, the progress ceased, and the pain at the spot of the fracture persisted.

Dr. Lange then proposed an operation, assuming that the nerve at the point of fracture was irritated by the callus and adhesions, and at that time Dr. Sands saw the patient in consultation, and approved of the proposed procedure. About four weeks ago, Dr. Lange performed it, and cut down on the inside of the elbow-joint against the protruding fragment, and found the following relations: the median nerve ran in front of the sharp edge of the bone in an angle, and at that point was somewhat flattened. Above that point it was somewhat swollen and thickened. The spindle-like swelling which he felt before the operation was a mass of muscular fibre belonging to the brachialis anticus. He loosened the nerve, excised the protruding fragment of bone, and since that time there had been decided improvement, both with regard to the facility of movements of the fingers and the use of the hand. The strength of the muscles which are supplied by the median nerve had not improved very much, and yet it seemed as if the cramped condition which existed in the flexor muscles was steadily decreasing. It seemed also that the extensor muscles had become more active since the operation. There was one interesting point, namely, that since the operation an entirely different and more normal form of nail was growing, and there were ridges on all of the nails alike, marking those parts of nail before the operation from that after it. The color and temperature of the skin had also markedly improved. Having been of a pale bluish before the operation, it was now of a more rosy tint. The temperature of the wound had become normal.

DR. C. T. POORE then read a paper entitled

SOME EXPERIENCE IN EXCISION OF THE HIP-JOINT.

He said: I do not think that I have anything new to offer in regard to excision of the hip-joint; the object of this paper is simply to call out discussion.

As far as my experience goes, suppurative disease of this joint has its origin in an osteitis, or osteomyelitis, as it is sometimes called, of the head of the bone, the articular cavity being involved secondarily. This paper is based on the experience in eighteen cases of excision occurring among the poorer classes and in hospital practice; they are not therefore to be compared with cases occurring among the better classes.

Ten cases occurred in girls and eight in boys; the youngest was two and a half, the oldest was fourteen years of age. The disease has lasted from two to sixteen years. Many of the patients had been under strict mechanical treatment for from one to four years without any effect on the course of the disease. Abscess continued to form and discharge, so that in not a few patients the thigh and gluteal region were riddled with openings, from which pus continually flowed, while in others only one opening had formed. Excision was performed in all cases in the same way, with a long incision over the trochanter major, the tissues separated from the bone, and the head removed; in thirteen cases above the trochanter minor, and in six below that point. In four cases, after some months, the end of the femur was excised.

The pathological conditions underlying the external symptoms mentioned above were as follows: in seven cases the disease was confined to the head of the bone, the shaft appearing healthy; in all these cases the cartilage had entirely disappeared, and in most the head was represented by tubercles, or lay loose in the cavity of the acetabulum. The shaft was diseased in eleven cases; by this I mean that the central cavity was enlarged at the expense of the compact tissue, so as in many cases to admit the finger. The external shell had in many places a worm-eaten appearance; the bone was of dark color, and so soft that a probe could be easily made to perforate it. In a few cases the cavity was filled with pus; the periosteum did not appear much thickened, but was easily separated from the shaft. The floor of the acetabulum was more or less diseased in all of the cases; it was perforated in four; it was extensively diseased in its upper and posterior border in nine. In two cases I have seen a perforation of the upper wall opening on to the dorsum of the ilium, the external edge forming a bridge over it. In one case there was extensive disease of the pelvic bones; in short, they were all cases of advanced disease, and the pathological conditions such as in other joints would call for excision.

The result in these eighteen cases was as follows: Two are still in the hospital, leaving sixteen to be accounted for. Of these, eleven died and five recovered—about thirty-two per cent. The causes of death were—from pure exhaustion, one; tubercular meningitis, one; septicæmia, one; phthisis, one; amyloid degeneration, seven, in one of these cases the wound had entirely closed at the time of death. Death did not take place in these cases for some time after the operation, varying from two months to four years. The immediate effect of the excision in these cases was an improvement in all respects. The patients were free from pain, increased in flesh, had normal temperature, and in most of them were able to be about, but the wound never entirely closed except in one case. Sometimes only a small sinus was left. After a time an examination with the probe or finger revealed the upper end of the femur bare and rough, and from its cavity unhealthy granulations growing; and an examination of the abdomen in many showed the liver enlarged, and disease of the kidneys. In some cases the end of the femur was re-excised, and the cut surface exhibited the same unhealthy condition. These patients died not *from* but *in spite* of the operation. Of the five patients in whom recovery took place, and by this I mean that the wound entirely closed, no sinus remained open, and the child had use of the limb. The disease had existed six years in one, three years in one, two years in three cases. In all these patients the family history was comparatively good. In two cases, at the time of the operation there was enlargement of the liver. In one of these, albumen in large quantity was present in the urine, and the patient had two quite profuse hemorrhages from the lungs. Section was made one inch below the trochanter minor on account of profound disease of the shaft, yet recovery took place. In the other case the disease was confined to the head of the bone.

In regard to the permanency of the cure, one case was heard from five years after leaving the hospital. He was going about and had good use of the limb. One I examined six years after; he was well, and had been following the occupation of an express driver. One was seen eighteen months after his discharge, and was well. The other two cases I have lost all trace of.

In regard to the amount of shortening in these cases, it varied with the duration of the disease, its extent, and the point of section. In four cases it was as follows: three-fourths of an inch; one and one-fourth at time of discharge, and one and three-fourths eighteen months later; seven inches five years after leaving the hospital. In one case, two inches.

The elements going to make the shortening after excision of the hip-joint are—first, the amount of bone actually removed; secondly, the amount of atrophy of the whole limb from disease and disuse, and thereby the amount of stretching of the band holding the end of the bone to the pelvis. Three of my cases walked well without either crutch or cane. One with seven inches shortening cannot afford to keep himself provided with a high shoe, although he can bear his weight on the limb; he therefore uses a crutch.

In referring again to the cause of death, it will be noted that in all but two patients, it was due to diseases secondary in their nature; namely, amyloid degeneration, tubercular meningitis, and phthisis. The deaths from septicæmia and exhaustion were due, one to the operation, and one to the joint disease. All the patients having amyloid disease belonged to families having a marked tubercular diathesis. In some cases these changes in the abdominal organs came on early; others, late, after suppuration had made its appearance. It would seem that from a study of these cases, and others in which no operation had been done, that there is a marked predisposition among children of tubercular parents who become thus affected in the course of hip-joint disease. I have never seen a case that was not so connected, and it would seem that the more profound the hereditary influence the earlier these changes appear.

Two of the patients operated upon had, at the time of excision, marked enlargement of the liver, and one albumen in large degree in her urine, yet both recovered, and on examination made five years later, in one the liver was found of normal size; the albumen disappeared shortly after the operation.

I have never seen a true dislocation of the head of this bone on to the dorsum of the ilium.

The questions that naturally suggest themselves from a study of these cases are: First, Was a cure by mechanical and expectant treatment probable? and, secondly, What are the indications for excision of the hip-joint?

In regard to the first, I am clearly of the opinion that a spontaneous cure was not probable. The fact that, in those cases that proved fatal after excision, the patient improved in all respects for a time, varying from six months to over a year, and that they finally died of secondary disease, would seem to corroborate that

opinion. I think that an earlier operation would have diminished this rate of mortality.

In regard to the second question, "What are the indications for excision?" I think that it is more difficult to lay down any rules. In cases giving a good family history much can be done by mechanical treatment, and I do not think that an early operation is called for. But in the class of patients belonging to families of marked tubercular ancestry, and in hospital practice, I think that the question of excision should be considered soon after abscesses have made their appearance, as there seems to be a kind of malignancy in these cases.

The presence of amyloid changes is not a bar to recovery, but is a very serious complication.

DR. SANDS said that he thought the rule followed by Dr. Poore, of postponing the operation of excision until the disease has reached a chronic stage, was better than the opposite rule of early interference. As already remarked by Dr. Poore, the cases which are seen in hospital practice are usually of an aggravated character, and, as a rule, have already been subjected to the rest treatment, and treatment by extension without avail, before they are admitted. He supposed, however, that all would agree that until these milder methods had been found to be unavailing, excision should be withheld; for it is a fact, that in private practice, where ample means are at our command, a very large number of patients with hip-joint disease recover, either with entire restoration of the functions of the joint in a few cases, or with anchylosis in other cases, thus obviating the risks attending excision of the bone. But, as Dr. Poore had remarked, when abscesses have formed and sinuses exist, and there is every indication that nature can do no more, and when by postponing an operation the general health of the patient becomes more impaired, and secondary changes in the liver and kidneys especially become probable, excision seems to be the only expedient to which surgeons can resort. It did not seem to him that the indications in hip-joint disease were different from those of disease in other joints, in which there is no question with regard to the propriety of surgical interference. His experience corroborates Dr. Poore's in this particular, that usually there is very decided amelioration of symptoms after performance of excision, and it would seem that this is more certain to occur now than formerly, when we paid less attention especially to drainage, and had got the advantage of antiseptic surgical dressings. He had operated twice within the last six weeks for excision of the hip-joint; both patients were children, one a girl six years of age, the other a boy nine years of age; both had been under observation for one year, and had well-marked disease with abscesses when they entered the hospital. In both, the operation was postponed, in the hope that the abscesses would disappear; but the general health of the children began to give way, and it was very plain that the disease would proceed to an unfavorable termination if left to pursue its natural course. In both cases the acetabulum had been perforated, and the extent of destruction reached nearly as far as the level of the trochanter minor. In both cases the femur at the point of section showed signs of osteitis, and in both the improvement after operation was very marked, although in one more so than in the other. The boy, whose appetite had already entirely failed, and whose pulse was very rapid, improved so much immediately after the operation that he was able to eat, while his pulse was very much diminished in frequency. In the girl the shock of the operation proved severe for a few days, but after that her general health began to improve, and the improvement had continued. He thought that surgeons should not abstain from the operation because a radical cure is not very likely to take place. It seemed to him that the palliation afforded by the operation was sufficient to justify its performance. Respecting complications in bad cases, such as degeneration of the liver and kidneys, while it is a general fact that such complications are fatal, it occasionally occurs that the enlargement of the liver either diminishes or disappears. He could recall one case, that of a lad twelve years of age, upon whom he operated in 1870, and in whom a very bad state of affairs existed at the time of the operation. There were extensive abscess and sinuses, and there was disease of the head of the bone and of the acetabulum, the latter, however, not perforated, and the general condition was such as to give but little expectation of a good result. But the wound healed, and although afterwards it reopened, no dead bone could be found. Finally permanent closure took place about one year after the operation; soon afterward the urine became albuminous, and two years later there was a very decided tumor in the abdomen, evidently formed by an enlarged liver. The boy has remained anæmic ever since the operation was performed, and although albumen still continues to be present in moderate quantities in the urine, the enlargement of the liver has disappeared, and the lad has grown to be a man, is now fairly well, and able to walk without any assistance except that derived from a thick-soled shoe. This boy's parents are living, and are in excellent health; there is no hereditary tendency to tubercular disease.

DR. J. C. HUTCHISON remarked that a few years ago there was a great disposition to excision of the head of the bone in cases where it would seem that the patients would recover without it. The tendency, however, had turned in the opposite direction, and probably many cases which should be operated upon were neglected until it was too late. It seemed to him that where the disease had resisted all the usual treatment, such as rest, extension, etc., and abscesses had formed, and the patient is gradually growing worse, and especially where there were some evidences of amyloid degeneration, that the operation is clearly indicated. He had seen a great many cases recover under the most adverse circumstances, with anchylosis, of course, and sometimes the deformity was such as might subsequently be remedied by an operation.

DR. BRIDDON had seen a number of cases like those reported by the author of the paper, and he thought that the majority of those in which perforation of the acetabulum had occurred terminated fatally. Cavities resulting from accumulations of pus within the cavity of the pelvis were difficult to drain. He had one specimen in which the perforation was large enough to have allowed the passage of the head of the femur, but it was not displaced in that direction. The most favorable result he had seen was in the case of a child, eleven months old; the excision was made in the Presbyterian Hospital. One year after, the shortening was little over a quarter of an inch, all the movements of the joint were free, the sinuses were closed, and the patient is now in robust health, and an inmate of the institution at St. Johnsland. In all the cases that he had seen, the patients were the children of tuberculous parents. In one case of long standing, in which the patient had recovered from the effects of the active processes of disease, he had judged that the caries had ceased, and that the numerous sinuses which refused to heal were kept open by the presence of a sequestrum. An explorative operation was made; the head and neck were gone, and the acetabulum was filled with a bony growth, in the centre of which was an imprisoned mass of necrosed bone. In that case, the sinuses persisted for a long time after the removal of the offending cause. He had recently seen a young

woman who was in the Presbyterian Hospital four or five years ago. All her sinuses had closed, and at times she could get about with tolerable comfort, but for a large portion of the time she was confined to her bed by pain. She had for some time suffered from diarrhœa, and he thought it possible that these discharges might indicate that the external sinuses had closed, because the pus had sought an outlet through the acetabulum and rectum, but an investigation in that direction did not sustain the suspicion. Would not the symptoms in this case warrant an explorative operation?

Dr. Sands asked Dr. Briddon if he meant to say that the children, in his cases, had tubercular disease.

Dr. Briddon replied that all these children were the offspring of parents suffering from phthisis, and that, although in most of these cases there were no evidences of visceral tuberculosis, he believed that the caries was tubercular, and he was inclined to think that we were coming back to the idea that tubercle was the cause of many of the cases of disease occurring in the cancellous structure of bone.

The President remarked that in deciding the question whether in any given case excision should be performed, he believed a much safer conclusion would be reached if the possibilities in these cases were always borne in mind. There is no case which is absolutely hopeless. Even cases in which perforation of the acetabulum has occurred and intra-pelvic abscesses exist, are not certainly and absolutely hopeless. In making up his estimate with reference to the result in any given case, he had been influenced in his judgment by one striking instance which he had seen. After languishing for a long time with numerous abscesses connected with disease of the hip-joint, a young girl, in whom the operation of excision seemed to be entirely indicated, and to whom it was recommended but refused, finally recovered. During the progress of the case, abscesses formed in the pelvis and discharged fecal contents, showing that there was communication with the intestine. The patient finally was able to walk upon the anchylosed limb, and many years afterward he saw her, and she had become a fleshy, healthy girl, with an appearance of the tissues about the hip-joint which was somewhat remarkable. In her thin, emaciated condition, the soft parts during the healing process had become united to the bone opposite each fistula, and the interspace between being gradually filled up with fat, left about the hip six or eight depressions nearly as deep as the length of his finger at points corresponding to those at which the old sinuses opened.

Dr. Sands asked the President if he did not consider such a result so sufficiently rare as not to justify the surgeon in accepting it as a criterion.

The President remarked that the result was extremely rare; nevertheless the possibility of such an occurrence he believed should be accepted, and should have its due weight in the mind of the surgeon when considering any individual case.

STRANGULATED HERNIA.

Dr. Gerster presented a specimen, and related the history of the case as follows: A working man, thirty-five years old, had had a reducible oblique inguinal hernia since his eleventh year, and had worn a truss for seventeen years. In the evening of January 30th a sudden abdominal pain compelled him to leave work, whereupon he, of his own accord, took a large dose of salts and went to bed. Vomiting and more pain supervening, the family attendant was sent for, who made an unsuccessful attempt at taxis. Fecal vomiting, intense local pain, with tenderness all over the belly, induced Dr. Gerster to have the patient transferred to the German Hospital, where herniotomy was practised January 31st. Eighteen hours after the beginning of the incarceration, ether being the anæsthetic used, the very large, tense, and somewhat reddened tumor was incised in its full length down to the sac. This being opened, some reddish serum escaped, and a large omental mass presented itself, which was found to be firmly attached to the lowest portion of the sac. Both pedicles having been secured by catgut ligatures, this was removed, exposing about ten inches of small, much distended, dark-red intestine. The strangulation now was relieved by the usual steps.. The strangulated portions of the gut were carefully drawn forth and examined. The knuckle of intestine showed no unequivocal signs of necrosis, was uniformly reddish-brown, not mottled or gray; its feel and turgor were normal, both at the convexity and at the places of strangulation, the serosa shining, so that it was deemed proper to replace it in the abdominal cavity. The sac, which was closed at its neck by a purse-string-like strong catgut suture, including the external ring, was cut away below this suture and entirely extirpated. The operation was finished by the application of a row of external sutures and an antiseptic dressing.

Immediately after the operation marked relief was felt, nourishment was retained, wind passed, and vomiting ceased. Five hours later the thermometer showed 103° Fahr., but the pulse was good and the patient felt well. Next day some meteorism, slight nausea, and a temperature of 103.5° Fahr. were noted, wherefore one grain of opium hourly and an ice-bag on the belly were ordered. On the third day after the operation nausea and meteorism had still more increased, and the patient's skin and sclerotic had attained a marked icteric hue. Temperature ranged between 102° and 103°, the pulse between 110 and 120 beats. The patient complained of pain in the hypogastrium, which, however, did not increase on pressure. The wound was found well united and without a trace of reaction, so that some of the absorbed catgut sutures could be wiped away. The night was passed badly, in spite of large quantities of opium. On February 4th it was reported that the patient, having vomited last night, had a violent coughing spell, when he felt as though something had given way, but not feeling any increase of pain, did not call the nurse. Next morning a knuckle of injected gut was found protruding from the open external wound; it had become firmly adherent to the walls of the wound by exuded lymph, and in view of the meteorism, vomiting, high fever, and generally bad condition of the patient, it was decided not to disturb the protruding gut, but rather to make an attempt at utilizing the state of affairs. The finger was carefully introduced into the inguinal canal, and it was ascertained that no strangulation was present, whereupon a long incision was made into the gut, and, some gas having escaped, a soft catheter was pushed well up into the upper part of the intestine, this portion having manifested itself by the escape of fecal matter. Thus it was hoped that more gas would escape. The patient died the same day at 3 P.M., with all the signs of a most acute septicæmia. It was noted that as the rate of the pulse rose the temperature declined, till shortly before death the temperature was 90° Fahr. Pulse filiform, and not to be counted.

Post-mortem examination revealed the absence of septic peritonitis. A small quantity of orange-colored, clear serum escaped from the cavity. The prolapsed gut lying in the wound belonged to the lower part of the ileum, and showed signs of adhesive peritonitis. In the left iliac fossa a mass of agglutinated slate-colored intestine was found, representing the hernial contents replaced at the operation. The places of strangulation were still clearly visible by a band-like depression at one end, and by a loss of continuity of

the serosa at the other end of the knuckle. Here the tissues were not necrosed, whereas at the convexity of the knuckle, where at the operation normal turgor and feel were present, an extensive portion of the gut was necrosed and shrivelled, but not detached. The intestine having been opened, a band-like coat of diphtheritic, grayish-white membrane was found closely adherent to the mucous surface, corresponding exactly with the sites of strangulation. The mucous space enclosed by these two lines was covered throughout by a multitude of round and confluent diphtheritic patches, some of which, being denuded of their gray coating, presented themselves as shallow ulcers. These ulcers appeared to be the same both over the necrosed and the non-necrosed portions. The mesentery was found turgid and reddened, but not necrosed. The cause of death was acute septicæmia from enteric diphtheria and necrosis, caused by a strangulation of eighteen hours' duration, and probably favored by the action of the laxative.

Here we had, then, a case of very acute strangulation, where at the operation for its relief the gut was found to be without signs of imminent necrosis, fairly turgescent, and where some five or six hours after the operation that portion of the intestine necrosed which had not been subjected to the direct pressure of the strangulating ring. Clearly, changes in the arterial blood-supply from the mesentery must have been the cause of this issue, and not direct pressure, as is most frequently the case. This is the second case of a similar nature occurring in the experience of Dr. Gerster, and he pointed to the insufficiency of our knowledge in determining at the time of herniotomy whether the given intestine will or will not undergo necrosis after replacement. He called attention to the fact that the external appearance of the hernial contents in many cases presented no reliable signs for determining the future of such an intestine, and that the surgeon still had to trust to good luck. A narrowing down of the limits of this class of cases was very desirable.

DR. BRIDDON said that some years ago he saw a German woman, in consultation with her physician, who had been suffering for nearly a week from symptoms of moderate strangulation. The right groin was occupied by a painful swelling; the skin was adherent to the subjacent structure; it was red and inflamed, and fluctuation was distinct. On dividing the tissues, a collection of pus was found external to the sac, which contained a knuckle of intestine, covered with granulations, and only very slightly adherent to the ring. The structure was divided, and the intestine was gently placed just within the ring. Everything went well until the seventh day, when, without the approval of her physician, and at the suggestion of an officious friend, she took an active cathartic. It operated through the natural channel and through the operation wound, which had been left open. The cavity of the peritoneum was not invaded. The fecal fistula gradually contracted and closed, and she got well.

He could recall another case of similar character which he had seen in consultation with Dr. Gillette. In that case there was suppuration of the sac. The gut was adherent to the neck of the sac, and it was sphacelated. The adhesions were not disturbed, the gut was opened, and the wound was left to close by granulation. Feces were discharged freely through the wound; but the amount diminished gradually. The fistulous channel contracted, and eventually healed. Several years ago he presented, at the Pathological Society, a specimen of strangulated intestine, which was removed from a woman, in whom the condition of prostration present did not appear to be warranted by the condition of the imprisoned gut, which was by no means much altered. The operation was followed by diarrhœa and death. He remembered that the late Dr. Krackowizer was present at the meeting, and expressed the opinion that death did occasionally occur after herniotomy from catarrhal inflammation of the intestine, due to the use of cathartics, administered before the strangulation was relieved, and which only commenced to manifest their action after the obstruction was removed.

DR. SANDS said there was one question which had not been broached in connection with the specimen presented by Dr. Gerster. He thought it was the rule with most surgeons in doubtful cases, to be careful to leave the suspicious portion of intestine at or near the abdominal ring, so that in the event of necrosis, an artificial anus would be likely to be established. He supposed that in the present state of our knowledge this is a proper rule. He could recall instances similar to those related by Dr. Briddon, where he had returned the intestine in this way, which subsequently became necrosed and led to the formation of an artificial anus, which subsequently closed spontaneously. In Dr. Gerster's case it would seem that death was not determined by peritonitis caused by the reduction of the intestine, but probably by septicæmia resulting from gangrene, which would have occurred equally if the intestine had not been reduced. This circumstance raises the question, whether it might be thought advisable to excise that doubtful portion of the intestine, and unite the edges of the remaining portion with sutures. This operation had been proposed and performed in cases where gangrene was manifest, and although theoretically such a procedure is correct, yet, experience has shown that the adjacent intestine is apt to be so much softened as not to be able to bear the strain of the sutures. Perhaps, however, in cases like the one narrated by Dr. Gerster, in which the morbid process had not far advanced, success might be possible.

DR. WEIR remarked, that in cases in which gangrene was recognized, the surgeon at once knew what to do. He was either to establish an artificial anus, or exsect the intestine, preferably the former. In the doubtful cases, it might be very difficult to decide which course to take, whether to cut off the strangulated portion of gut altogether, since the present specimen showed, with others he had seen, that there was risk of subsequent gangrene, or to partially replace it as already mentioned, and await the result. In one instance he had encircled the intestine with a loop of catgut, the ends of which projected from the wound, to keep the intestine in the neighborhood of the ring. The case, however, did well, and no use was made of this loop, which dissolved in the discharges.

The PRESIDENT remarked, that he had been guided chiefly by the condition of the capillary circulation, in answering the question whether or not the vitality of the gut would be retained. If, after pressure with the fingers, the return of the circulation is feeble and imperfect, he had always felt that the intestine was doomed to die.

DR. GERSTER thought we were unable in every case to apply satisfactorily this test mentioned by the President, as in many cases the gut was so engorged and thickened that pressure could only be made so far away as to be of no special value for determining the exact condition of the circulation in the portion which had been strangulated.

The PRESIDENT replied that he had always been able to decide the question satisfactorily for himself, after freely dividing the stricture, and he thought that, by the exercise of a little patience, the condition of the capillary circulation could be ascertained.

DR. WEIR exhibited an instrument devised by Mr. Treves, of London, for

SUTURING DIVIDED ENDS OF INTESTINE

after the removal of a gangrenous or diseased portion. The details of the instrument are to be found in the *British Medical Journal* for December 12, 1882.

THE OVARIAN CORPUSCLE.

Dr. Briddon presented a specimen of fluid removed by aspiration for diagnostic purposes from a tumor in which there was doubt as to the true nature of the disease. The whole abdomen was filled by an elastic, but non-fluctant tumor. The history gave no clue as to what point it started from. It was immovable, and its connections, if any, with the uterus could not be made out. The fluid was of the color and consistence of golden syrup, was alkaline in reaction, and its specific gravity was 1014. Heat transformed it into a coagulum which was dissolved by boiling with two volumes of acetic acid, determining the presence of paralbumen, regarded by some as significant of ovarian disease. Under the microscope he found some few epithelial formations, and a number of large, round, granular corpuscles, also considered as pathognomonic of ovarian cystic growths. In conjunction with this, Dr. Briddon presented a specimen of fluid which he had removed the day before from the tunica vaginalis of an old gentleman. This he also treated by the chemical test applied to the first specimen, and demonstrated the presence of paralbumen. Continuing the examination, he found under the microscope the same large, round, granular corpuscles—monster leucocytes.

Dr. J. C. Hutchison then exhibited a *Simple form of Ether Inhaler.*

PHILADELPHIA ACADEMY OF SURGERY.

Stated Meeting, December 4, 1882.

The President, Prof. S. D. Gross, in the Chair.

Dr. Ferdinand H. Gross reported

A CASE OF TRIGEMINAL NEURALGIA RELIEVED BY LIGATURE OF THE CAROTID ARTERY, AND NEURECTOMY,

which is published in full in the American Journal of the Medical Sciences for April, 1883. He gave a condensed clinical history of the case extending over nine years, with an account of the various remedial measures undertaken for its relief. The result of the operative treatment may be summarized as follows:

1. The effect of the ligation of the common carotid artery was immediate relief in the domain of the first and second divisions of the trigeminal nerve; the period of immunity from pain in the second division being fully two years, while in the first division the pain has never returned, the relief there being probably permanent, and can only be accredited to the carotid ligation. The effect of this operation upon the third division of the nerve was too transient to count for anything.

It should be added that no impairment of intellect has followed the ligation. After the lapse of nearly two years and a half no disturbance of brain functions has been noticed either by Dr. Gross or the patient, or by any of those who are habitually associated with him.

2. The first neurectomy of the inferior dental nerve, eight months later, resulted in a period of relief from the neuralgia of about one year and three months—to remain within safe limits.

3. The last two operations, viz., the neurectomy of the superior maxillary and the repetition of the operation upon the inferior dental nerve, were performed within two months of each other, September 14th and November 11th, respectively, and may be considered together. The result thus far is entirely satisfactory, the patient being now, three months later, completely relieved of the neuralgia.

The President, after thanking the lecturer of the evening for the interesting and exhaustive manner in which the subject had been presented, remarked that the paper was well worthy of elaborate discussion, and requested Prof. Bartholow, who was present as a visitor, to give his experience from a medical point of view.

Dr. Bartholow expressed his gratification at the privilege afforded him in listening to the paper, which he thought was full of instruction, but would prefer to suspend final judgment as to the ultimate result of the operations until a longer time, say six months, had elapsed. While he could not speak of the subject as a surgeon, he would say that he had used, with good effect, in severe cases of neuralgia, deep hypodermic injections of chloroform, and in a number of instances with permanent good result. From five to fifteen minims was the quantity injected, but it was necessary to lodge the chloroform deeply and near the nerve-trunk. In only one case in his experience had there been any trouble from the formation of abscess after the use of this remedy.

Dr. Brinton stated that he had performed neurectomy three times, but in his experience there had been but little permanent good. In all the cases, the pain had returned in from six to twelve months. During that time, however, the patients were more or less comfortable, and regarded from this point of view, the operation would seem justifiable, as affording temporary respite from suffering.

Dr. Packard said he had operated on one case, in 1869, trephining the anterior wall of the antrum, drawing out the nerve and dividing it far back.

The patient, a gentleman from Minnesota, had suffered extremely for twenty-four years. He derived immediate relief from the operation, which lasted at least for six months after his return home; since which time Dr. Packard had not heard from him.

Dr. Willard related his experience with a case in which the inferior dental nerve was divided by trephining the ramus of the jaw. The patient had been a sufferer for five years, and had become addicted to the hypodermic use of morphia in enormous doses. The relief was partial for six months, when, the pain returning, a second operation was done, resecting an inch of the nerve, since which time, now six years, there has been no return of the disease.

Dr. Nancrede said that the remark made by Dr. F. H. Gross, with reference to the possibility of seeing the foramen rotundum through the orbit in some skulls, whilst in others it could not be seen, seemed of much interest, since Dr. Gross had shown on the two skulls he presented, that a somewhat different manipulation would be necessary in order to divide the nerve close to its point of emergence from the cranium. A cursory glance would show that these two skulls presented marked examples of two types of orbital fossæ, viz., the quadrate and the rounded. In the former, the transverse diameter is fully one-third greater than that from above downward, while in the latter they are nearly equal. Where then the transverse diameter very much exceeds that from above downwards, the floor of the orbit is, as it were, *raised*, and the foramen rotundum hidden from view; whereas, when the opposite measurements obtain, this opening can be seen. Dr. Nancrede then pointed out that the junction of the external angular process of the frontal bone with the malar, could be readily detected on the living subject as well as, approximately, the suture between the internal angular process of the frontal with the nasal process of the superior maxillary bone. Measuring between these two points would give the transverse diameter.

Again, the supra-orbital notch or foramen is usually readily detected; while a line dropped from this point with a slight inclination outwards, will strike the margin of the orbit just above the infra-orbital foramen, which opening can be usually detected by careful palpation. Measurement between these points of the orbital margin would give the diameter from above downwards. By comparing the diameters, Dr. Nancrede thought that one could predicate before an operation, whether the foramen rotundum could or could not be seen from the operation wound. It might seem a point of small importance, but in a delicate operation like that performed by Dr. Gross, the minutest details were of importance, and "forewarned was forearmed."

DR. JOHN B. ROBERTS was especially interested in the result of the ligation of the common carotid artery; and, as the relief of pain was probably due to cutting off the blood current from the central portion of the nerves involved, suggested that ligation of the internal carotid might be as beneficial. This, as shown by Wyeth, can readily be done just above the level of the top of the larynx.

DR. R. J. LEVIS remarked, that in operations upon the inferior dental nerve he had sometimes found it difficult to draw the nerve out. In an edentulous jaw this might possibly not be so.

DR. F. H. GROSS, in closing the discussion said Dr. Nancrede's remarks upon the anatomical points of the orbit were interesting, as showing the possibility of determining in advance of an operation by external measurements the variations in the orbits of different skulls; but no matter what peculiar formation these measurements might lead him to suspect, he would still prefer Wagner's method of operating, although in some cases nice manipulation might be required to divide the nerve far back.

In Langenbeck's and Hüter's subcutaneous operations, the nerve was divided in the spheno-maxillary fissure, but in Wagner's the nerve is brought into view, and can be divided at a more central point, even at the foramen rotundum and behind Meckel's ganglion. In this operation, too, the violence done to the superior maxillary bone, as in Carnochan's mode and some others, was avoided.

As to Dr. Robert's suggestion to tie the internal carotid, the speaker thought he would prefer to boldly tie the common carotid. The object was, of course, to lessen the intra-cranial pressure and irritation. He further remarked that whilst it was unfortunate that the neuralgia sometimes returned after neurectomy, they had nevertheless heard of patients being relieved for years, and sometimes permanently, and that relief, even for a short time, from the atrocious pain of this malady was a great boon. He was fully in accord with the writer who had said: "the possibility of relapse should not militate against resection."

NOTE.—March 19, 1883, "at this date, over *four months* after the neurectomy of the inferior dental, and over *six months* after the operation upon the superior maxillary nerve, the patient continues entirely free from neuralgia."

CORRESPONDENCE.

PHOTO-MICROGRAPHY.

To the Editor of THE MEDICAL NEWS.

SIR: I have read, with much interest, the paper by Dr. Piersol, of Philadelphia, on "Photo-micrography by Lamp-light," in your issue of March 17th. Perhaps I may be permitted, as one who has worked in this special field for several years, to supplement his article by a few words of my own. I quite agree with his eulogy of the "dry-plate" process, having used the gelatine process extensively myself, and the "emulsion" process before it, with great success and satisfaction.

It is of great importance to line all the apparatus with a dull-black material; for the microscope tube, I always use a pasteboard lining covered with black velvet, and for the camera and extension shellac varnish made very thick with lampblack, and applied till the surface is perfectly dull when dry. If care is not taken, the black will crack off from the internally projecting edges of the bellows and produce a spot capable of reflecting light, so that I now use a bellows camera of my own make, in which the bellows part is lined with velveteen. Using a "Hartnack" stand, I find the draw-tube too narrow, and get better results by taking it out entirely, and replacing it by a velvet-lined tube of pasteboard. I have used the "Keystone" dry plates with much satisfaction, and can recommend them. The most difficult part of the manipulation is, undoubtedly, the focusing, and I may state that for a good many years I have dispensed with the ground glass, which has always been a source of error and delay, as well as necessitating some machinery to reach the focusing screw. I now use the following arrangement with great ease and comfort: A suitably sized hole is cut in the side of the camera bellows, and a glass plate covered with white bristol-board is used instead of ground glass, the operator viewing the image thrown on the white surface, which makes it very sharp and distinct; the least change in the focus being at once apparent. During exposure the hole is covered with a piece of velvet. If this mode is used, the position of the operator allows him, in almost all cases, to dispense with any cords or levers to move the focus-screw, as he can easily reach it with one hand. I have used objectives from four inches to one-sixteenth inch focus, and find the actinic and visual foci practically identical. With very high power objectives it is often useful to possess a camera with a focusing screw of its own, as this allows of a more gradual change of focus, by advancing or withdrawing the focusing screen, than can be accomplished when the microscope screw is used alone. As regards the objects suitable for photographic reproduction, I can only re-echo the words of Dr. Piersol: sections *must* be *very* thin, deeply stained, and sharply differentiated.

Yours very truly,

NELSON B. DE S. SIZER, M.D.

336 GREENE AVENUE, BROOKLYN, N. Y.,
March 30, 1883.

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

A COMPLIMENTARY DINNER is to be given Dr. Oliver Wendell Holmes, of Boston, on April 12, 1883. Among the committee appear the names of Drs. Fordyce Barker, T. G. Thomas, J. C. Dalton, D. B. St. John Roosa, Cleveland, Sturgis, McLane Hamilton, and Draper.

EXTIRPATION OF THE UTERUS.—Dr. Wm. T. Bull, of this city, has performed his second successful extirpation of the entire uterus. There seems to be an unusual rivalry between the "pure surgeon," and the gynecologist just now, which threatens to assume formidable proportions.

THE COUNTY SOCIETY'S NEW DELEGATES TO THE STATE SOCIETY.—The election of three delegates by the conservative party, the other evening, was an unexpected blow to the supporters of the new Code. The lethargic old party has aroused itself, and, under the

leadership of the younger Flint, appeared in full force at the meeting of the County Medical Society, at the College of Physicians and Surgeons, on Monday, and elected Drs. Leale, Ward, and Hitchcock by a majority of twenty. The end is not yet. Grim threats of a process just now in favor in Ireland, and known as boycotting, is hinted at. It is a significant fact that three homœopathists have resigned from their local county society since the passage of the new Code.

The Death of Dr. W. H. Van Buren has saddened the profession during the past week. Dr. Van Buren was one of the courtly medical men of the old school, who are rapidly passing away, and was respected not only for his great talents, but for his personal nobility as well.

NEW ORLEANS.

(From our Special Correspondent.)

Smallpox.—Until within the past two or three days, the weather has been unusually cool for this latitude. This almost continuous low temperature has had its influence in perpetuating the epidemic of smallpox now prevailing in this city. Hot weather not only invites open windows and doors of sick chambers, but beyond question both shortens the period of vitality, and lessens the noxiousness of smallpox contagium. During the week ending March 17th there were 56 deaths from this disease; the total mortality of the city being 172. The week ending March 24th, gave 65 death from smallpox; total mortality 179. At a meeting of the Board of Health, held March 27th, a paper was read, which reported 331 deaths from smallpox since January 1st, of which 213 were colored. Nine hundred and seventy-seven cases have been reported, and, as the reader of the paper adds, "showing that two-thirds of the cases had not been reported." There is a city ordinance requiring all cases of infectious diseases to be reported to the Board of Health, under a penalty of fifty dollars fine. This statement of the common neglect to observe the city ordinances in regard to infectious diseases, is disheartening to all our efforts to arrive at a better condition of sanitary matters here. It is hoped that the ordinance which has just passed the City Council, giving the Auxiliary Sanitary Association power to employ twenty-five sanitary inspectors, will in a great degree furnish the remedy for this evil by detecting and bringing to punishment all violators of official sanitary laws.

The Medical Department of the University of Louisiana held its commencement last week. The number of graduates in medicine is seventy-four; in pharmacy eight.

The majority of the members of the Medical Faculty agree in the opinion, that the average excellency of attainments as shown in the final examinations, is above that which is usual.

A Pollen Shower.—In referring to the meteorology of this season, it may be mentioned that on the night of March 16th, a shower of rain fell in this city, which brought a copious deposit of pollen from some "wind-wafted pollen" plant or plants. Such occurrences are by no means uncommon in this State, and yet a very large number of people consider them ominous of some portending evil. The color of the pollen was yellow, and as it formed very perceptible lines along the edges of pools of water, the ignorant took it to be brimstone. Indeed a person of education asked your correspondent if this phenomenon was not ominous of a yellow fever epidemic during the coming summer. There is no observation, so far as we know, which affords an exception to the declaration made half a century ago, that no clouds of dust, or organisms visible to the naked eye, are capable of originating pestilences.

VIENNA.

(From our Special Correspondent.)

Spina's Studies on the Bacillus Tuberculosis.—Dr. Arnold Spina has just published a book composed of two parts, the first of which gives a historical review of the histological and experimental work done in the department of tuberculosis, while the second is entirely devoted to Dr. Koch's recent startling discovery of the pathogenetic element of tubercle. We pass over the not very conclusive results obtained by an examination of the literature of tubercular disease, preferring to dwell on the second part of Dr. Spina's book, which alone contains original research.

Our readers are well aware of Dr. Koch's arguments in favor of the infectious origin of tubercle. By applying a new method of coloring, he succeeded in detecting what he believes to be a new specific organism, and sought to establish its relation to tubercular disease by two important facts. First, this organism—a bacillus—is nowhere found but in tubercular material, from which it is never absent; and, second, when cultivated and inoculated upon hitherto healthy animals, it causes well-characterized tubercular disease.

Now Dr. Spina's conclusions are opposed to both of the foregoing results; he contests both the specificity of the organism and its bearing on the origin of tubercle.

The specificity of Koch's bacilli, based as it is on their not being stained in a watery solution of vesuvin, when previously colored by an alcoholic solution of methylene-blue, Spina attempts to subvert by closer examination of Koch's proceeding. He shows that the same bacilli can be stained by a watery solution of methylene-blue, that they do not resist the action of acids, as Ehrlich, who demonstrated them by another method, is inclined to think; he even claims to have succeeded in staining them with vesuvin. He further points out that the bacilli rendered visible by Koch's and Ehrlich's methods are of highly varying shape and dimensions, and often present a striking likeness to other bacilli from non-tubercular material, which do not react with aniline color in the same manner.

If neither the reaction with aniline colors nor the outward appearance are sufficient to single out Koch's bacilli as peculiar organisms, Spina might well have spared himself the second series of his experiments, which are meant to show that no substantial connection exists between Koch's bacilli and tubercular disease. He detected a few bacilli brought out by Koch's method in the sputa of apparently healthy men, and in putrefying blood of the frog; he failed to find them in miliary tubercles of the peritoneum in man, and could not state their constant occurrence in the lungs and sputa of phthisical patients. He repeated Koch's experiments on the culture and inoculation of the bacilli, and detected no bacilli in the organs of the animals inoculated.

In conclusion, he grants that Koch's bacilli occur in greater number in tubercular material than elsewhere, and that the substance obtained by Koch's culture-experiments is more likely to originate tubercular disease than indifferent material, but he denies that our knowledge of the origin of tubercle has been advanced by Koch's researches.

We do not think, however, that Spina has made out his case, and we beg to offer some remarks on his observations. If the bacilli of tubercle be stained by a watery solution of methylene-blue as well as by an alcoholic one, and do not resist the action of acids, the

specificity of the organism does not seem endangered by these methods of treatment. Even the most impressive among Spina's arguments, the discharging the methylene-blue from the bacilli by protracted action of vesuvin, is not altogether conclusive, for Spina does not contest the fact, that the bacilli in question resist vesuvin for some time, or that they can be made more distinct by a short exposure to the brown solution. It is this very peculiarity upon which Koch's method of distinguishing them from other bacilli relies. If Spina's observations prove true, they only prove that the chemical difference between the bacillus of tubercle and other bacilli is not so striking as was thought at first.

Spina's objections gain additional strength from the observation, that bacilli of different shapes are stained by Koch's proceeding. Whether there be several genera of bacilli, which agree in their behavior with he aniline color mentioned—we must remember that the bacillus of leprosy, though well distinguished by other chemical reactions; is possessed of the same peculiarity—or whether the one bacillus of tubercle is the subject of so great a variation in shape and dimensions, we should keep in mind the fact that the problem cannot be solved on this ground; because the outward appearance of a bacillus is not conspicuous among its characteristic features. In short, Spina's objection is not sufficiently sustained to make one doubt the existence of Koch's bacilli, although it suggests the wish that a better method for demonstrating them, relying on deeper chemical differences, could be found.

Considering the ubiquity of tubercular products in the air, we should not think it strange if a few specimens of the bacillus of tubercle can be detected in putrefying blood and other material prepared very likely in the rooms of the Vienna Hospital. Nor do Spina's examinations of the sputa of healthy people prove fatal to the diagnostic value or pathogenetic importance of the bacillus. Among twenty-four persons, only four presented the bacillus in their sputa, and of these four apparently healthy persons, one showed a flatness of the chest and dulness under the right clavicle; a second is described as possessing the well-known phthisical habitus, and only two are beyond suspicion of past or latent tubercular affection; yet the bacilli are very few in number and all the persons mentioned belong to the medical profession and pass their days in the great Vienna Hospital and Pathological Institute.

Spina's researches on the occurrence of the bacilli in sputa of phthisical patients and in miliary tubercles of serous membranes, where they cannot be deposited from the air, would be of the utmost importance were they not completely contradicted by the results arrived at by other inquirers. If Spina failed sometimes to detect bacilli in phthisical sputa, and never could reveal their presence in miliary tubercles of the omentum, Koch and others seem to have been happier, never missing the same organism in the same material. Here is assertion standing against assertion, and we must still prefer adhering to Koch; not only because one positive observation outweighs many negative ones, but also because Spina appears to have abandoned Koch's elaborate methods for the detection of the bacillus and neglected the use of Abbe's condenser in searching for them.

Spina's culture-experiments seem to have utterly failed, as is evident from his own statements. He never obtained a really sterilized gelatine to carry on the experiments, and all his preparations were lost by gradual drying up, which had to be carefully avoided in Koch's experiments. Yet Koch's cultures of the bacilli constitute a highly momentous link in the chain of proofs for the existence and pathogenetic bearing of the bacillus of tubercle.

To sum up our short review, we are of opinion, that Spina's book falls far short of a refutation of Koch's theory, which it is evidently intended to be, but we believe that it will do good by directing the attention of inquirers to the want of a more precise and thoroughly reliable method of demonstrating the bacillus of tubercle.

THE NEW CODE.—In a communication published in *The Medical Record*, DR. CORNELIUS R. AGNEW says: "There is not much in the New Code that I strongly desire to see retained. I am quite ready to abolish all but one or two clauses of it. I do wish, however, especially to see the clause retained which binds us all to acknowledge the public necessity for a "legally qualified practitioner." "Members of the Medical Society of the State of New York and of medical societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine." It is permissive, not mandatory. I wish to see the profession united to contend for that. . . . The medical man whom the State has pronounced to be a legally qualified practitioner, this chartered State Society cannot disfranchise, however much we may despise him or refrain from social communion or fellowship with him. We cannot discipline a member of our society if his conduct is in conformity with the law of the State."

POLYCLINIC IN RIO DE JANEIRO.—On November 15, 1882, a polyclinic was opened in the above-named city, under the direction of the distinguished Dr. Moncorvo.

SECTION ON OBSTETRICS, AMERICAN MEDICAL ASSOCIATION.—Members and delegates proposing to present papers before the Section on Obstetrics and Diseases of Women, at the meeting of the American Medical Association in June next, are requested to forward at once, or as soon as practicable, the titles or subjects of such papers, to Dr. J. K. Bartlett, Chairman, Milwaukee, Wis.; or to Dr. G. A. Moses, Secretary, St. Louis, Mo.

THE HEALTH OF SURGEON-GENERAL BARNES.—Ex-Surgeon-General Barnes, who has been ill for a long time, is yet quite sick, but has shown signs of improvement within the past few days.

THE JEFFERSON MEDICAL COLLEGE held its annual Commencement in the Academy of Music, on April 2d, at 12 M. The degree of Doctor in Medicine was conferred on 227 candidates. Dr. Addinell Hewson, on behalf of the Alumni, presented to the Board of Trustees a bust of the late Dr. Joseph Pancoast, Emeritus Professor of Anatomy. Dr. J. M. Da Costa, Professor of the Principles and Practice of Medicine, delivered the Valedictory, which was entitled "The Higher Professional Life."

NORTHWESTERN MEDICAL COLLEGE, ST. JOSEPH, MO.—The third annual commencement of this college was held on the evening of February 22, 1883. The degree of Doctor in Medicine was conferred upon eighteen candidates. Dr. S. F. Carpenter delivered the valedictory on behalf of the faculty.

THE NEW YORK COUNTY SOCIETY AND THE NEW CODE.—*The Medical Record*, in commenting on the New York County Society's recent election of Old Code delegates to the Society, comforts itself with the following reflections: "This result was saluted as a great victory. We trust that those who so announce it will have the fairness to add some of the accompanying facts. The vote was obtained by means of systematic canvassing and a preliminary caucus. Printed ballots

were supplied and all the machinery for securing the desired end was put in action. The other side, which has already polled twice the number of votes cast at the last meeting, was taken by surprise and made little preparation for so vigorous a campaign."

The Medico-Chirurgical College of Philadelphia, at its Second Annual Commencement, on Thursday, March 26th, conferred the degree of Doctor in Medicine on ten candidates.

Dr. Ferdinand Ritter Von Arlt, Professor of Ophthalmology in the University of Vienna, has had the Cross of the Order of Francis-Joseph conferred upon him by the Emperor, on account of his many valuable services in the profession.

A Vice-President of the American Medical Association on its Code.—*The Medical Record* publishes the following extract from the late Presidential address before the Minnesota State Medical Society of Dr. Alexander J. Stone, now Vice-President of the American Medical Association:

"The Code, since its final adoption, has apparently been laid upon the shelf by the side of the family Bible, to be treated with almost as much reverence, to be read quite as seldom, and to be quoted only when its provisions enable one to discipline a rival, or to exclude him from the benefits of professional affiliation. A judicial consideration of the Code forces a conclusion that much which it contains is gratuitous insult to the profession, and more, is rather calculated to amuse than to impress with respect to the mind of the layman. There is not a clause or sentence in the first two articles which is not absolutely true; but, should the self-evident truths contained in Article I. be held constantly before the physician, as if by nature he was a brute who was to be taught the ordinary laws of humanity; a fool who must be taught a wisdom in the management of his patients which instinct alone would inculcate; a knave who must be withheld from empiricism; or a man without the instincts of a gentleman? Granted that men enter the ranks of the profession to whom the epithets of 'fool,' 'knave,' or 'clown' apply, of what value are the platitudes concerning brotherly love, or of what good is a formulated code defining the relations of medical men to the public or to each other? Among gentlemen such a code is unnecessary; among pirates it only serves to foster a cathauling hostility; as between a gentleman and a pirate, any difficulty which may arise is not to be satisfactorily settled by a reference to any code, because the standpoints from which each looks at matters differ too widely—nor are the penalties which the code imposes such as to deter a real rascal, nor is that unsovereign body, the medical profession, able to enforce its laws rigorously."—*Med. Record*, March 31, 1883.

Government Experimental Farm for Animals.—The Department of Agriculture has leased a piece of ground near the northeastern boundary line of Washington, to be used as an experimental farm and hospital in connection with investigations of diseases of animals. The grounds are being put in order, and buildings are being erected thereon. Dr. D. E. Salmon, who has for a number of years been employed by the Department in the investigation of diseases of cattle, swine, and poultry, will arrive in Washington about May 1st to take charge of the work. Dr. Salmon will bring with him a number of cattle and sheep, and the experiments will begin shortly after his arrival. The Pasteur system of inoculation will be adopted, with such additions and qualifications as have been suggested by Dr. Salmon's own discoveries while engaged in investigation at his farm near Asheville, N. C. The investigations now to be made will be on a much larger scale than any heretofore attempted by the Department, and will be conducted with the view of ascertaining the origin, causes and nature of the Texas cattle fever, pleuro-pneumonia, and hog and chicken cholera, together with means of preventing and curing these diseases.

Jefferson College Alumni.—The annual meeting of the Alumni of the Jefferson Medical College was held on Saturday, March 31st, Professor S. D. Gross in the chair.

The Committee on the Gross Professorship of Pathological Anatomy, presented a report, stating that considerable progress was being made towards accomplishing the project.

The following officers were elected for the ensuing year: President, Samuel D. Gross; Vice-Presidents, Drs. Addinell Hewson, R. J. Levis, Ellwood Wilson, and W. W. Keen; Recording Secretary, Dr. Thomas H. Andrews; Corresponding Secretary, R. J. Dunglison; Treasurer, Dr. Nathan Hatfield.

Life-saving on Railroads.—The Austrian Government Sanitary Council has prepared a set of regulations for life-saving on railways, and a guide to first help to those injured by accidents until the arrival of a physician. These have been sent to the several railway companies for examination and suggestions. Every conductor is to be provided with a leather case of bandages; a litter to be placed at every station and halfway between such stations as are more than nine miles apart; at every station a small case of surgical instruments, of specified kinds, is to be kept; a larger supply of instruments and bandages at stations fifty and sixty miles apart, where there are reserve locomotives, which locomotives are to pick up the cars and litters on the way to an accident. Still more complete provision is to be made at important stations where there are many servants. For every two hundred and fifty or three hundred miles of road, at an engine house, there must be a hospital car, of a specified pattern, used for carrying sick and wounded in time of war. The "guide to first aid to the injured" prescribes how the servants or others shall carry the victims of accidents, how place them, treat their wounds, apply bandages, transport them in the cars, and what to do in case of sudden illness.—*Sanitary Engineer*, March 15, 1883.

The Public Health in Connecticut.—The Secretary of the State Board of Health reports that pneumonia and acute diseases of the lungs take the leading place among the causes of death in February. The epidemic of scarlet fever, while subsiding in the cities first attacked, is extending into the State extensively, except the southwestern part, where measles and whooping-cough are more prevalent. Measles is also prevalent in some parts of Litchfield County. The epidemic of scarlet fever was quite severe in Hartford, causing sixty deaths since October. Diphtheria has been nearly as fatal, but shows signs of decrease.

There has been a peculiar type of disease in the State, which, as far as can be learned, appeared for the first time in New England this winter. It is called winter cholera. It was prevalent in Providence, R. I., and followed shortly after in Waterbury. Last year there were accounts of it in certain western cities. It appears in an epidemic form. No local cause has yet been found to be even usually associated with it. The disease is wrongly called cholera, for it does not produce death directly, and very rarely, if ever, indirectly. The symptoms are profuse watery discharges which

evidently come from the blood; severe cramps; a pinched, sunken countenance, that is, the eyes appear sunken. After well established, there is a cold stage, the temperature falling to ninety-seven degrees, and cases are reported as low as ninety-six degress; the average temperature in health being ninety-eight and one half degrees. The average duration is four days. The symptoms somewhat resemble those of cholera, hence the name. Thus far, cities only have been attacked. The Board of Health has learned of no genuine case originating in the country. In most places the cases have been mainly among the prosperous, well-to-do citizens. In only one epidemic has a cause been assigned that was at all probable. There the poor, living in tenement-houses, only were seized, and suetine, or rather lard butter, which was poorly prepared, was charged as the cause; but this appears hardly probable, as no such association has been since found to exist. It is a peculiar disease, but easily controlled by treatment. A few cases similar to the winter cholera are reported from Cheshire.

The connection between foul air and pneumonia has been shown repeatedly. Persons coming out of ill-ventilated rooms, after breathing polluted air, which has already induced some congestion of the lungs by its irritating qualities, readily take cold, and a congestion which induces inflammation is easily excited. It is well known that there is a type of pneumonia induced by foul, polluted air, even without subsequent exposure to the colder air out of doors. Sewer gases from bad plumbing, or imperfect drains, contaminated air from polluted soil around the house, by heaps of decaying filth or saturation by kitchen and other refuse, if drawn into the house or habitually breathed, so depress the system and lower vitality that disease is readily engrafted.

In New Haven measles and whooping-cough have been more prominent, although cases of scarlet fever appeared during the month. In Cheshire, New Canaan, Thomaston, Plainville, and a few places widely separated, measles is quite prevalent, while bronchitis, influenza, catarrhal diseases, and pneumonia prevail generally.

The sanitary history of the year compares thus far unfavorably with its predecessor, due mainly to climatic causes. A few cases of malaria are reported, some fatal. Unless it is supposed that the virus lies dormant, we have cases originating at all seasons, but less often in winter and in cold weather.

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending March 24, 1883, indicate that erysipelas, inflammation of the bowels, and bronchitis have increased, and that scarlet fever has decreased in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported, during the week ending March 24, and since, at seventeen places, scarlet fever and measles each at sixteen places, and smallpox at one place.

OBITUARY RECORD.—Died, at Detroit, on the 8th of March, D. O. FARRAND, M.D., in the forty-fifth year of his age.

Dr. Farrand was born in Ann Arbor, Mich., in 1838, and pursued his medical studies at the College of Physicians and Surgeons, New York, from which institution he received his degree of M.D., in 1863. He then entered the regular army as assistant surgeon, but resigned at the close of the war, and settled in Detroit, where he rapidly acquired a large practice and prominence as a citizen. He was a member of the Detroit Board of Health, Surgeon to Hooper's Hospital, Surgeon of the Detroit Metropolitan Police, Surgeon-in-Chief of the Michigan Central Railroad, and Chief Medical Examiner of the Michigan Mutual Life Insurance Company.

——At Tübingen, on March 19th, aged seventy-one years, VICTOR V. BRUNS, the distinguished surgeon and Director of the Department of Clinical Surgery at the University of Tübingen. Prof. v. Bruns was well known by his contributions to the surgery of the larynx, as well as by a text-book on surgery, a work on the laryngoscope, and papers on nasal polypi.

——At Paris, on March 20th, 1883, of diabetes complicated with albuminuria, CHARLES-ERNEST LASÈGUE, Professor of Clinical Medicine in the Faculty of Medicine of Paris, in the 67th year of his age.

Prof. Lasègue was one of the editors of the *Archives Gènérales de Mèdecine*, and enjoyed a high reputation from his scientific *critiques* in that journal, and his works on Mental Alienation. In 1867, he succeeded Andral in the Chair of General Pathology, for which he was ably fitted, having been two years previously, in the Chair of Clinical Medicine at La Pitié. At the Palais, where he often appeared as an expert or a witness, he had made considerable reputation by his humoristic eloquence.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 26 TO APRIL 2, 1883.

BARNETT, RICHARDS, *Captain and Assistant Surgeon.*—To proceed to Fort Adams, Rhode Island, and report to the commanding officer for duty at that post.—*Par. 1, S. O. 51, Department of the East, March* 28, 1883.

CRONKHITE, HENRY M., *Captain and Assistant Surgeon.*—Relieved from duty at Fort McKinney, Wyoming Territory, and assigned to duty as post surgeon at Fort Fred. Steele, Wyoming Territory.—*S. O. 31, Department of the Platte, March* 22, 1883.

DE LOFFRE, AUGUSTUS A., *Captain and Assistant Surgeon.*—Granted leave of absence for three months.—*Par. 3, S. O. 71, A. G. O., March* 27, 1883.

LORING, L. Y., *Captain and Assistant Surgeon.*—To proceed without delay to Fort Schuyler, New York Harbor, and report to the commanding officer for duty as post surgeon.—*Par. 2, S. O. 51, Department of the East, March* 28, 1883.

MOSELEY, EDWARD B., *Captain and Assistant Surgeon.*—To report in person to the president of the Army Medical Examining Board, in New York City, for examination for promotion, and upon completion to return to proper station.—*Par. 3, S. O. 70, A. G. O., March* 26, 1883.

PAULDING, H. O., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Laramie, Wyoming Territory, and assigned to duty at Fort Sidney, Nebraska.—*S. O. 31, Department of the Platte, March* 22, 1883.

SKINNER, JOHN O., *Captain and Assistant Surgeon.*—To report in person to the president of the Army Medical Examining Board, in New York City, for examination for promotion, and upon completion to return to proper station.—*Par. 3, S. O. 70, A. G. O., March* 26, 1883.

TAYLOR MARCUS E., *Captain and Assistant Surgeon.*—To report in person to the president of the Army Medical Examining Board, in New York City, for examination for promotion, and upon completion to return to proper station.—*Par. 3, S. O. 70, A. G. O., March* 26, 1883.

TURRILL, HENRY S., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Fred. Steele, Wyoming Territory, and assigned to duty as post surgeon at Fort McKinney, Wyoming Territory.—*S. O. 31, Department of the Platte, March* 22, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia*

ORIGINAL LECTURES.

ON THE TREATMENT OF NEURALGIA.[1]

A Clinical Lecture

BY PROF. DUJARDIN-BEAUMETZ.

MEMBER OF THE ACADEMY OF MEDICINE, PHYSICIAN TO THE HOPITAL ST. ANTOINE, ETC., PARIS, FRANCE.

GENTLEMEN: I purpose devoting a lecture or two to that very common affection which you will often have occasion to treat, and the therapeutics of which you ought well to understand—neuralgia.

Despite the recent extensive researches into the functions of the nervous system, we have not yet precise and certain data concerning neuralgia, and we are compelled to define this affection by the principal characters which it presents, and neuralgia is still a symptom rather than a pathological unity. Without entering here into a discussion respecting the structural diseases of nerves, and the neuralgias, which are veritable neuroses, I believe that the symptom known as pain is produced whenever there is molecular alteration or modification of sensory nerves. I do not believe in "essential" neuralgias, and I am persuaded that when we come to understand better the physiology and pathology of the nervous system, that word *essential*, which only conceals our ignorance and our uncertainty, will disappear from the nosological category.

What is of importance for us to know from its bearing on the treatment of the neuralgias, is the pathology and etiology of this affection; on this point I must dwell briefly. I have told you before that in order that the functions of the nervous system may be regularly and normally performed, three conditions must be fulfilled. There must be: 1. Integrity of the nervous system itself, cells and fibres; 2. Integrity of the circulation; 3. Integrity of the nutrient blood. The sensory system of nerves is no exception to this law, and every circumstance, whether connected with the state of the blood or the bloodvessels, which modifies these nerves or their centres, may give rise to pain. Let us consider each of these conditions separately.

From the standpoint of the nervous system, all alterations, from the profound modifications of neuritis to simple molecular disturbances, may be the point of departure of the clinical syndrome described under the name of neuralgia; wounds of nerves, irritation, compression of nerves, inflammation of the neurilemma, neuritis properly so called, are all so many causes of persistent neuralgias. It has even been claimed that rebellious neuralgia is always neuritis. In my opinion, if inflammation of a nerve sometimes gives rise to a stubborn neuralgia, we are not to conclude from this that every persistent neuralgia is of inflammatory origin, for some quite obstinate facial neuralgias have a different origin.

As for circulatory troubles, they have a manifest influence on the production of neuralgic phenomena, and in this regard two sorts of neuralgia may be distinguished; those which result from want of blood—anæmic neuralgias, and those which result from excess of blood—congestive neuralgias, to which Gubler first called attention.

It is to these disturbances of the circulation that neuralgias due to the impression of cold have been referred, and which are so frequent. Some explain them as the result of anæmia of the cutaneous extremities of sensory nerves, others as the result of congestion of the nervous centres. The question is more complex than one would suppose, and it is impossible at the present day to decide it one way or the other. Lastly, in certain cases alterations of the blood constitute the point of departure of the neuralgia; it is in this way that chlorosis, the influence of certain poisons, of the marsh miasm, of certain diatheses, may give rise to veritable dyscrasic neuralgias. Whether resulting from alteration of the blood, of the nervous system, or from circulatory disturbances, these diverse modifications may affect the sensory nerve in three points of its course: its periphery, some part of the main trunk, or its central termination.

At the periphery, every cause which, through traumatism or atmospheric changes, modifies the terminal sensory fibre, may determine a neuralgia which shall spread to all the ramifications of the nerve. As an example, I refer you to dental neuralgia. A carious tooth produces some alteration of the dental pulp, and an irritation spreads along the dental nerve, causing pain in all the branches of the trifacial. The annals of medicine are full of similar facts, where we see neuralgias persist for years, in consequence of the presence in the tissues of foreign bodies which irritate the peripheral extremities of sensory nerves. But in order that there may be a painful sensation, a sentient cell must be touched; and this is a point on which Vulpian, Anstie, and especially Vanlair, have insisted. It is then well understood that if theoretically there exist peripheral neuralgias, yet in order that there may be phenomena of pain the neuralgia must be central.

These preliminaries being settled, we will now enter on the treatment of the neuralgias; but in order to pass in review the numerous therapeutic measures recommended in these cases, I shall be obliged to establish a certain number of divisions. Therapeutic agencies applicable to neuralgia may be classed in two distinct groups—the one addressed to the symptom pain which characterizes the neuralgia, this is symptom treatment; the others are directed to the cause of the pain, this is pathogenetic treatment.

Symptom treatment is subdivided into three groups. In the first are placed all medicaments which act by modifying more or less profoundly the functions of the nervous system, and which are described under the name of hypnotics, anæsthetics, analgesics, anti-neuralgics, etc., such as opium, chloral, chloroform, and aconite. The second group contains medicaments which act by substituting for the pain, another pain, and constitutes revulsive or substitutive medication; we place here vesicatories, cauterizations, etc. The third group contains substances which experience has shown to have powerful anti-neuralgic properties, but the mechanism of whose action is not known, such as turpentine, guarana, and sulphate of copper.

I shall first briefly examine the medicaments of the three divisions of the first group, then the bases of the pathogenetic medication, and finally shall take up, in order, certain forms of neuralgia and their treatment.

In the first group stand prominently forth, opium and its derivatives, chloral and chloroform, aconitine and gelsemine, electricity and hydrotherapy.

Opium is undoubtedly one of the means the most

[1] Translated from advance sheets by E. P. Hurd, M.D., of Newburyport, Mass.

employed in the treatment of pain in neuralgia, and since the introduction into medicine, by Wood, of hypodermic injections, it may be truly said, that it is on subcutaneous injections of morphia that we rely most to subdue pain, or at least to obtain temporary alleviation.

Is it necessary to make the subcutaneous injection *in loco dolentiæ?* Some, and Chouppe in particular, have answered this question affirmatively. I do not think so. If morphine relieves neuralgia, it is not by any local action on a nerve or nerves in a painful region, but by modifying the sensory nerve-centre; the anodyne must first enter the circulation and be carried to the heart, then sent to the cerebro-spinal axis, before it can have the effect sought. The injection then may be made with equal advantage on the thighs, hips, or the fleshy part of the arm, wherever it can be made the most easily.

You may use Magendie's solution made with cherry-laurel water, or any other good menstruum that will not ferment; the average dose being one or two centigrammes. Constantine Paul recommends water that has been boiled. If you use common water, mucedines will be sure to form in your solution after a few days. Bardet has shown that these aid in the transformation of morphia into apomorphia.

These subcutaneous injections, which have supplanted all other modes of administration of opiates in the treatment of neuralgias, have one great disadvantage, and only one—the patient easily becomes habituated to them, and resorts to the hypodermic syringe, not to obtain relief from pain, but an excitation which henceforth becomes a necessity. That will be a curious chapter of pathology, which shall describe the progress of morphomania in our times; it will show that it has almost always been the case that inveterate and deplorable habits of morphia-taking have had their origin in the use of hypodermic injections of that anodyne in the treatment of neuralgia.

When the hypodermic method was first introduced, Wood, in Great Britain, and Behier, in France, employed atropine, but this medicament was soon abandoned on account of the dangers which it presented, and the delirium which frequently followed its use. At the same time you may derive benefit from the association of the two medicaments, and I recall to your remembrance the formula which I habitually use:

R.—Sulphate of atropine, . .	0.01 (gr. ⅙).
Hydrochlorate of morphia, .	0.10 (gr. iss).
Cherry-laurel water, . .	20.00 (℥vss).—M.

A cubic centimetre (15 m.) or about a syringeful of this solution, contains half a milligramme ($\frac{1}{128}$ gr.) of atropine, and half a centigramme ($\frac{1}{12}$ gr.) of morphia.

It has been asserted that injections of plain water would relieve pain as effectually as injections of morphia, and Dieulafoy has given his support to this statement. I showed in 1872 that only injections of morphia can be relied upon to calm the pain, and that any occasional anodyne effect produced by injections of water, is due to distention or rupture of certain muscular fibrillæ.[1]

Chloral is one of the best anodynes that we possess; it has only one inconvenience, that it cannot be administered a great while to the same individual without determining by its caustic and irritant action a chronic inflammation of the digestive tube. Therefore, I have recommended, in order to obviate this inconvenience, to give the chloral preferably by enema; the following combination administered *per rectum* will do good service. Take the yolk of one egg, beat it up in a gill of milk, and dissolve one or two grammes of chloral. Administered in this way, the chloral, however, in a few days irritates the rectal mucous membrane, and must be suspended

Certain derviatives of chloral have been proposed as a substitute, and croton-chloral has been especially vaunted by Liebreich, Benson Baker, and others in Germany and in France. Croton-chloral and butyl-chloral are given in the dose of thirty centigrammes to one gramme every three hours, till the paroxysm disappears; despite the advantages which this remedy possesses in tic douloureux, it is little used in the treatment of neuralgia.

Chloroform is also in current use in the treatment of neuralgia; it is employed almost exclusively locally, occasionally, however, by inhalation in the case of neuralgias that are horribly painful. Locally it is used in the form of liniment, or injected subcutaneously. Aran, Dupuy, De Frenel, and others, advised a long time ago to treat neuralgias locally by compresses wet with chloroform, and recently Brown-Séquard has experimentally demonstrated the analgesic action of these local applications. But it is especially in hypodermic injections that this medicament gives good results.[1]

Introduced into therapeutics by Roberts Bartholow, of Philadelphia, then by Doe, of Boston, the usage of subcutaneous injections of chloroform did not become general in France till Ernest Besnier made his favorable report. I have myself made trial of this method in my hospital practice, and my pupil, Henry Fournier, has given the results in his thesis. In order that these injections of chloroform may do good, they must be made in the painful region, and they must be introduced deeply in the cellular tissue, or muscular interstices; neglect to follow this rule has resulted in accidents, and in failure. Plunge your needle, then, perpendicularly into the tissues, and carry it as far as the guard at the proximal extremity. This mode of treatment is hardly applicable to any form of neuralgia except sciatica.

By these subcutaneous injections of chloroform you may obtain two different results—either disappearance of local pain after small doses, or general effects, characterized by sleep, when you inject two, three, four, and even ten grammes of chloroform, without, however, at any time obtaining surgical anæsthesia. Why do you not obtain complete anæsthesia? It is because chloroform, when introduced beneath the skin, is absorbed by the veins and lymphatics, and carried to the lungs before entering the arterial system to be distributed to the brain and other nerve-centres, and in the lungs it is in large part eliminated. What remains uneliminated, and such portion of the vapor of the chloroform as, after being expired, returns to the lungs in the air of inspiration, passes into the blood of the aortic system, and is carried to the brain, where it has

[1] The fact that intense pain is sometimes relieved by a hypodermic injection of water, has been attested by a great many observers. Gubler, who has many times witnessed the phenomenon, explains it as the result of a local infiltration, not only of the cellular tissue, but of the histological elements as well. There are degrees of hydration of the tissues, and there is a marked relation between this hydration and divers modes of sensibility; witness cases of anasarca, in which the infiltrated tissues are relatively insensible, as you will see by testing the sensibility over the œdematous parts, and over the surrounding region not invaded by the anasarca. The aqueous injections succeed the best, according to Gubler, in those neuralgias which are called congestive.—*Vide* Gubler, *Cours de Therapeutique*, p. 238, Paris, 1880.

The whole subject is far from being clear.—TRANS.

a more or less sedative effect, according to the quantity which has escaped the eliminating action of the lungs. In producing surgical anæsthesia by inhalations of chloroform, you practically suppress the principal source of elimination, and charge the arterial blood with the toxic agent.

By the side of these medicaments, and even at their head, we must place aconite and aconitia, which give marvellous results in certain varieties of neuralgia, and especially in facial neuralgia of the congestive form. Experiments have shown that aconitia has an action quite special on sensory innervation, and in particular on that of the trifacial, and it is this action which Oulmont, Séguin, Franceschini, and Laborde have utilized in the treatment of neuralgia. You can then make use of the crystallized nitrate of aconitia, and as there exist impure aconitias in commerce, you would do well to order the preparation of Duquesnel. The granules of Duquesnel contain each one-quarter of a milligramme of aconitia; you may give one of these granules every three hours till eight are taken in the course of twenty-four hours.

Crystallized aconitia is one of the most energetic poisons; and you ought rarely to exceed the dose of two milligrammes a day; there are some patients even in whom, owing to their susceptibility to the drug, this dose cannot with safety be reached. You ought then to suspend the medicine when the patient complains of an uncomfortable sensation of constriction of the mouth and eyes, and tingling in the tongue, which are the first toxic manifestations. When you cannot obtain aconitia, you can employ the tincture of the root (the tincture of the leaves is not to be relied on). Of the common tincture of aconite root, you may give ten drops every three hours. [Fleming's tincture is much stronger, and should not be given in a larger dose than five drops, at least as a commencing dose.] The tincture is much inferior to aconitia, at least, in the treatment of facial neuralgia. I cannot too highly commend the alkaloid in prosopalgia; since I have been in the habit of using it, I have obtained cures in a great many cases, and always an amelioration.

In my judgment gelsemium sempervirens and gelsemin merit a place far below aconite and aconitia. In the rich, moist soils of Virginia and the Carolinas grows a climbing plant with yellow flowers, called the yellow or Carolina jasmine; it is the gelsemium sempervirens. From the root and stalk is obtained an alkaloid called gelsemin, discovered by Fredigke. A tincture is made from the root, which is given in the dose of ten drops every two hours. This tincture has been made the subject of experimentation by Wickham Legg, Cordes, of Geneva, Hill, of the United States, Spencer Thompson, Sidney Ringer and William Murrell, Massini, Suraszc, Roberts Bartholow, and others, who have obtained remarkable results in the treatment of facial neuralgia, and neuralgias especially of the paroxysmal or intermittent form.

I was the first in France to experiment with this tincture, and my pupil, Dr. Eymery-Heroguelle has reported the results in his thesis of graduation (August, 1877). I obtained certain favorable results from the tincture, but I found it an uncertain medicament. Moreover, the tinctures were of no definite and uniform strength, a fact due probably to the circumstance that in making the fluid preparations all parts of the plant, as well as the roots, were used, or possibly because pains were not always taken to obtain the fresh, green root; as a consequence, the same doses sometimes gave toxic effects, sometimes no effect at all. In one of our patients, symptoms of poisoning, of the utmost gravity, from the medicinal use of the tincture were noted. Such toxic phenomena have already been often reported as the result of the free use of this tincture, and Hanna, Freeman, and Courtright have even known death to follow. I have, therefore, abandoned, in the treatment of neuralgias, the use of this drug, as being uncertain and dangerous. These inconveniences may be avoided by the use of gelsemin; but this alkaloid is little known, having been as yet little studied, and seems much inferior as an anodyne to aconitia.[1]

In the same group of medicaments, we must place electricity and hydrotherapy, which modify more or less directly the nervous system.

Electricity is one of the most active agents in the treatment of rebellious neuralgias. In my lecture on "Medical Electricity," I told you that electricity modifies the molecular state of nerves during its application, and sets up polar currents in the nerves which prolong its effect; you need not be surprised, then, at its beneficial effect in neuralgia.

You may make use of faradic or galvanic currents; the latter are much to be preferred. The negative pole is applied near the nerve-centre, the positive pole (which is the truly sedative pole) may be moved over the different painful points of the affected nerve. When you are treating tic douloureux, your currents should be very mild, and should not exceed three or four milliampères. In fact, too intense galvanic currents applied in the region of the encephalon, determine two effects which we ought to avoid—syncope on the one hand, and certain photopsias on the other; it is well, then, to use very light currents.

In the case of sciatica, your current should be much stronger; twenty milliampères, and even more. When treating of electricity in medicine I gave you a definition of this term (milliampère), and told you that it was the basis on which are graduated all our modern galvanic machines and the only scientific means at our command of comparing observations relative to the medical application of electricity. In the treatment of neuralgia it is necessary to be precise as to the quantity, if we would employ electro-therapeutics to advantage.

As for the duration of the current, authorities are far from being agreed, some recommending prolonged, others very short sittings. I think, with Apostoli, that the duration of the *séance* cannot be fixed in advance, and that the passage of the current should be continued till the pain disappears, or at least till some mitigation is obtained.[2]

---

[1] Numerous fatal cases are on record in American journals of poisoning by gelsemium. Thus, Pinkham's case in the *Boston Med. and Surg. Journ.*, for 1876; that of Boutelle, of Boston, in the same journal; that of Wormley, in the *Amer. Journ. of Pharmacy*, 1870; also that of Seymour, in the *Therapeutic Gazette*, for 1882. Freeman's three cases (referred to in the text) occurred in 1860; death occurred from taking one or more (in one instance, less than one) teaspoonful doses of the tincture. I myself came near dying four years ago from the effect of a drachm dose (given through mistake) of Wyeth's fluid extract of gelsemium; there were dimness of vision and double vision, irregular breathing, the most alarming prostration, and general muscular paralysis; the use of electricity and stimulants (capsicum, quinine, and strong coffee) brought me out of danger in a few hours. The toxicological history of this drug is well summed up by Ringer, in the *Lancet* for 1878.

Despite the danger attending the use of gelsemium in large doses, I have found moderate doses (five to ten drops of the tincture every two hours) a charming remedy in facial and especially dental neuralgias.—Trans.

[2] In the treatment of neuralgia, faradic, galvanic, or static electricity may be employed.

Induced currents.—Becquerel was one of the first to recommend the use of very strong and rapid currents. He advised the extra current and a wet sponge for electrode, and directed to apply the positive pole over the part of the nerve nearest the nerve-centre, and the negative pole over the divisions of the nerve; to be passed to and fro. *Seances* of five minutes' duration.

Duchenne preferred the revulsive method—the painful region to be electrified by the metallic brush; a very strong current with

It is in proceeding in this way that Remak, Onimus, Bouchaud, Craddock, Ouspenski, etc., have obtained results that are truly marvellous in the treatment of obstinate neuralgias, and especially in neuritis. I, myself, employed as far back as 1872 these constant currents in the treatment, more especially, of sciatica, and one of my pupils, Dr. Cado, has given the results (often most gratifying) in his thesis.[1]

But if electricity, methodically employed, may mitigate and cure neuralgic pains, you should repudiate altogether those "electric" (?) chains, belts, and pads, which you see advertised for pain, and especially for the cure of migraine. These contrivances are so badly constructed that they are incapable of generating any current, and can have no effect at all, unless a moral effect by acting on the imagination of the patient.

Hydrotherapy, like electricity, is one of the most active agencies in the treatment of neuralgia. Cold water acts, not only by modifying directly the neurility of sensory nerves, but also in promoting healthy circulation and nutrition, and I know of no better means of arresting a paroyxsm of neuralgia, or even of preventing the return of an attack than the douche.

Next in order come the surgical measures, which have a direct action on the painful nerve. These are: 1. Neurotomy; 2. Neurectomy; 3. Nerve-stretching.

1. The section of nerves for the relief of neuralgias is quite an old operation, having been performed more than a century ago by Maréchal in numerous cases. The results are generally temporary and disappointing. Simple division of the diseased nerve is not enough, and neurotomy has given place to (2) neurectomy, which consists in resection of a portion of the nerve; this operation gives permanent cures, the *rationale* of which is easily understood when you recall to mind the way nerves undergo regeneration. This method, which is only applicable to regions where the sensory and motor nerves are distinct, as in the face, has been signally successful in those painful affections of the fifth nerve known as tic douloureux, and I have a case in point to relate which I am sure will interest you all.

The subject, a patient of mine, was head-clerk in the Hotel Monnaies. This man, for three years, had been a sufferer from a most atrocious facial neuralgia. All medical means had been employed without any decided amelioration. Opium, aconitia, electricity, had failed to give more than momentary alleviation, they could not prevent the return of the cruel paroxysms; the poor man, in despair of a cure, was meditating suicide. Such cases are not exceptional, and you will meet with them in your practice.

It was an infra-orbital neuralgia—perhaps one of the most painful of the facial neuralgias. I advised resection of the upper maxillary nerve, and the operation was performed by my colleague and friend, Terrillon. The nerve was sought at its point of emergence from the foramen, and followed into the floor of the orbit; the terminal portion of the nerve, to the extent of two or three centimetres, was excised. From the moment that the man recovered consciousness from the ether to the present time, now two years, he has had no return of the pain, and the triumph of the operation is complete.

Is the operation always so successful? Unfortunately, no; and many instances are on record where branches of the trifacial have been resected for painful affections, and with the utmost skill and thoroughness, with no result but aggravation of pain to the patient and mortification to the surgeon. In fact, in these cases the neuralgia was undoubtedly central, and it is easy to see that remedial measures which are efficacious when the cause of the disease is peripheral, are useless, and worse than useless, when the prosopalgia owes its origin to some morbid condition of the encephalic trigeminus centre.

Neurotomy and neurectomy being, as we have seen, applicable only to facial neuralgias, it has been proposed, in cases of mixed nerves, where the operation of nerve-section would inflict on the patient a motor paralysis almost as distressing as the neuralgia, to resort to another operation, of quite modern origin, known as nerve-stretching.

Practised for the first time in 1872 by Billroth and Nussbaum, it was not till 1876 that this operation found favor with French surgeons, and Verneuil was the first in our country to attempt nerve-stretching, and this for traumatic tetanus. Since then the operation has become general throughout Europe. Chauvel has given us a very complete *résumé* of the history of this operation in Europe down to 1881, and from his monograph, we find that fifty-two cases of neuralgia had been treated in this manner; in thirty of these cases a permanent cure was obtained, in twelve there was a decided amelioration, and ten were unsuccessful. I have not time to enter into these details, which enable us to appreciate, at its just worth, this therapeutic measure, and which consists, as you well know, in exposing the trunk of a nerve and making more or less forcible traction on the same.

Generally, after the stretching the pain disappears, but it is liable to return in a short time; yet in a good many cases the benefit obtained is permanent.

---

rapid interruptions. This is the method of "electric fustigation" employed by Tripier.

Galvanic currents.—Magendie employed electro-puncture with the galvanic current; this process is now abandoned.

Remak, Ramios, Rosenthal, and Meyer make use of a centrifugal or descending current; positive pole in the vicinity of the nerve-centre, negative pole at the periphery.

Onimus also uses the descending current; placing the positive pole over the point of emergence of the nerve, the negative pole over the terminal branches, and passing for fifteen minutes a current of thirty elements of Remak. He advises weak currents, but of long duration.

Niemeyer, Tripier, Apostoli, and Bardet, on the contrary, recommend to apply the positive pole over the *point douloureux*, and this is the practice of most electro-therapeutists at the present day.

Static currents.—Arthuis has treated with great success a large number of neuralgias by Franklinic electricity. He employs the electric bath, and the electric brush, which is moved over the branches of the painful nerve.

As for the treatment of certain forms of neuralgia—facial neuralgia and gastralgia—this is the procedure of Bouchaud, Craddock, Apostoli, and Beard.

Apostoli employs, in the case of gastralgia, positive polar electrization of the pneumogastric: positive electrode over the pneumogastric, negative pole in the hand of patient.

Bouchaud treats odontalgia by a constant current of ten elements; positive pole on the face as near as possible to the painful nerve, negative pole on the antero-lateral region of the neck. In a few minutes' time marked relief is generally obtained.

Craddock has used the constant current with success in neuralgia of the face. Beard has long insisted on the treatment of neuralgias by electricity. In facial neuralgia, galvanization and faradization rapidly cure, but care and prudence in the use of these means are necessary. In gastralgia, galvanization gives complete success; in sciatica, ameliorates or effects a cure. In the latter malady, Beard recommends to apply one of the poles to the vertebral column at the point of emergence of the nerves; the other pole to be moved up and down the sciatic nerve, and the current to be especially directed to the *points douloureux*. (Beard on the "Treatment of Neuralgia by Electricity," in the *Practitioner*, 1873; and in Beard and Rockwell's *Medical Electricity*. Remak on *Galvano-therapy*, 1860. Onimus and Legros, *Medical Electricity*, Paris, 1872. Bouchaud on "Constant Currents in Odontalgia," *Bull. de Therap.*, tome lxxxv. p. 1. Craddock, "Trigeminal Neuralgia Treated by the Constant Current," *Practitioner*, 1873. Tripier on "Electric Revulsion," *Courrie Medical*, 1870. Apostoli, "Treatment of Gastralgia," *Bull. de Therap.*, 1882, etc.)

[1] L. Cado, "On the Treatment of Sciatica by Galvanic Currents" (*Th. de Paris*, 1872).

How does this elongation of nerves operate in the alleviation of pain? This is a question which we are unable to answer. The more probable supposition is, that the stretched nerves have a reactive influence on the sensory spinal centres, an influence which somehow favorably modifies the molecular state of the cells; this view receives support from the fact that very powerful tractions often do the most good.

Billroth has of late advised to practise what he designates subcutaneous elongation of the sciatic nerve. Struck with the distribution of nerves and bloodvessels in the inferior member, which pass, the former to the posterior part of the thigh, and the latter to the anterior portion, Billroth thought that by flexion of the thigh on the pelvis he might, without injuring the vessels, make energetic traction on the sciatic nerve. This is his manner of proceeding: The patient being completely relaxed from chloroform, the thigh is flexed on the abdomen, and the leg is forcibly *extended* on the thigh till the toes almost touch the head of the patient. This second part of the operation demands great care in its performance. The biceps, semi-tendinosus, and semi-membranosus muscles powerfully resist this movement, and too much violence would result in rupture of these muscles or their tendons, or even dislocation of the head of the femur. After this flexion and extension, the limb is placed in its natural position.

You have seen me this year perform this subcutaneous elongation in three cases. In one, the patient was unable to walk, from an obstinate sciatica, which had lasted three months; here, subcutaneous nerve-stretching brought immediate, permanent cure. In the other two, the benefit was temporary. You remember, too, that it was in arranging the preliminaries for an operation of this kind, that we met with that lamentable accident which caused such consternation among us; I refer to the sudden death from chloroform, whose details have been published by the medical press.[1]

Nevertheless, the misfortune that then happened to us does not militate against the utility of an operation which has now been so often performed with benefit. I believe, then, that in sciaticas rebellious to all therapeutic measures, we are warranted in attempting subcutaneous nerve-stretching, which is doubtless a safer operation than that of cutting down on the nerve, as is usually done, at the junction of the lower and middle third of the thigh, lifting out the nerve with the forefinger, and pulling on it with a force of forty or fifty pounds.

In my next lecture, I shall finish what I have to say on the treatment of neuralgia.

ORIGINAL ARTICLES.

A YEAR'S WORK IN OVARIOTOMY.

By WILLIAM GOODELL, M.D.,
PROFESSOR OF CLINICAL GYNÆCOLOGY IN THE UNIVERSITY OF PENNA.

During the past year I have had twenty-five cases of completed ovariotomy, with six deaths. In not a single instance have I declined to operate; for I have given every woman her chance; but I had two cases which I did not complete. One was a patient of Dr. Charles A. Currie, of Germantown. The cyst contained pus, and communicated with the bladder by a very small opening. On January 24th, after making an exploratory incision, and finding that the cyst was adherent at every point, I did not attempt its removal; but I simply emptied it and put in a drainage-tube. The recovery was slow, but without a bad symptom; and the woman left the hospital in about two months. The other case was a patient of Dr. Emil Fischer. When I was called in, she had had septic fever for six weeks, and I found the cyst tympanitic at every point. She was bed-ridden; her temperature was 102.8°, and her pulse 140. She also had a bed-sore, night-sweats, a red-raw tongue, and incessant vomiting. Notwithstanding her desperately low condition, I had her removed to my private hospital, and decided to give her a chance—hoping against hope that there might not be any other complications. On February 21st, with the help of Drs. Emil Fischer, B. F. Baer, T. V. Crandell, and W. L. Taylor, I began the operation. The cyst was universally adherent, and as soon as I began to enucleate it, I saw that my patient would die on the table. So I contented myself with opening the cyst, cleansing it out, and putting a glass drainage-tube in. The contents of the cyst were fairly rotten, and the puff of fetid gas which escaped from the incision was overpowering. The relief, however, was too late, and the lady died fifteen hours later.

I had also in my private hospital a successful case of nephrectomy; the first operation of the kind ever performed in Philadelphia. The patient was a lady from Salt Lake City, brought to me by Dr. J. F. Bird, of Philadelphia. I at first mistook the cyst of the kidney for one of the ovary, but was soon undeceived. The operation was not an easy one, for I had to strip off the investing coat of the peritoneum, to which the intestines were adherent. On account of a very severe bronchitis and an aphthous mouth and throat, the convalescence was slow; but the lady ultimately got well. This aphthous condition of the mouth and fauces was a very remarkable one. I have seen nothing like it, and I cannot help thinking that the additional work thrown on the remaining kidney must have had something to do with it.

In the following table of twenty-five cases a very unusually large number of double ovariotomies will be noted. There are twelve of them, with three deaths. Of these fatal cases, one, a girl aged 17, died in my private hospital, from acute peritonitis. The other was also a young girl, aged 16, who was operated on in a private-room of the Hospital of the University of Pennsylvania, and died from septicæmia on the ninth day. The third was operated on at home, and died either from shock or from œdema of the lungs. She was in a very feeble condition, and the operation, from pelvic and parietal adhesions, was difficult and tedious. The ether in this case acted badly; the patient becoming cyanosed, and showing afterwards bronchial irritation. I did not see her after the operation. The cysts in these two girls were small, and without serious adhesions. I was greatly disappointed at the result.

From this experience, I am disposed to think it better in such cases to wait until the tumor has developed, and by pressure has so altered the character of the peritoneum as to lessen its vulnerability.

83	Dr. C. W. Gerry, Trenton, N. J.	43	S			Nov. 14.	Univers. Hosp'l.	Omental.	L	30 "	"	"	Died.	A pedunculated fibroid also removed. Patient died on eighth day from acute mania.
84	Dr. L. P. Morawetz, Baltimore, Md.	17	S			Nov. 19.	Private Hosp'l.	None.	R L	15 "	"	"	"	Died from acute peritonitis.
85	Dr. J. Simpson, Philadelphia.	31	M	2		Dec. 24.	Home.	Parietal, omental, and pelvic.	L R	50 "	"	"	"	Was greatly debilitated, and died from shock.

In all these cases of double ovariotomy, the second ovary was removed because, in every instance, it showed evidences of cystic degeneration. But, as my experience ripens, I feel more and more inclined to extirpate both ovaries in certain conditions. For instance, in future, I shall remove both ovaries whenever the womb contains a fibroid tumor. By so doing, the growth of the fibroid will be checked. Again, whenever the woman has passed the climacteric, I deem it good policy to remove the second ovary, however healthy it may be, in order to take away the chance of its future degeneration.

With regard to the three other fatal cases, a word is needed. Case 71 was in every sense of the word a forlorn case, and operated on from a sheer sense of duty. She was thirty-nine years old, and had borne two children. Ten years ago the tumor was first discovered, but it remained quiescent until two years ago, when it began to grow rapidly, and she came on from Windsor, Vermont, with very indefinite ideas of having something done for it by internal medication. I first saw her on March 27th, and found her bed-ridden with diarrhœa, rectal tenesmus, high temperature, rapid pulse, and night-sweats—and I diagnosticated a suppurating cyst. As she was unwilling to be operated on, even to be tapped, I put her in charge of Dr. T. V. Crandall, who did all in his power to control these symptoms and get up her strength. She, however, became worse; delirium set in; her pulse ranged from 120 to 140 beats; her temperature from 101.5° to 103°. As she plainly had but a few days to live, I aspirated on April 7th, emptying four cysts from two different punctures. The stench from the putrid fluid was abominable. This operation gave her some relief for a few days, but she soon became worse than before. So, on April 15th, as a forlorn hope, I decided to remove the cyst at her boarding house, as she was too ill to be removed to the hospital. Drs. B. F. Baer and T. V. Crandall, and my son aided me in the operation; and it was witnessed by Dr. J. H. Rogers, of Sag Harbor, N. Y., and Drs. J. V. Shoemaker, W. Cruice, Vanderbeck, Milliken, and Schwenck. The tumor was a polycyst of the left ovary, with also many exogenous, or outside cysts, each one containing putrid matter. The cyst was adherent at every point up to the pedicle itself, which was short but slender, was much thickened, and glued wholly to the tumor. In breaking up the adhesions in each flank, an abscess outside of the tumor was torn open, and the contents escaped into the peritoneal cavity. Some of the outside cysts also burst and emptied themselves into the same cavity, giving out a sickening stench. The reflected fold of the peritoneum, together with the bladder, was carried up on the cyst-wall as high as the navel, and needed very careful dissection. The right ovary could not be found. Several times during the operation the woman seemed about to die on the table, but she was resuscitated by subcutaneous injections of ether and brandy. She subsequently rallied enough to converse with her friends, but she died about midnight from shock. Altogether, this was the most formi-

dable operation that I have yet performed, and it is a question in my mind whether, under the circumstances, I ought to have undertaken it; but, knowing that it was her only chance, I felt it my duty to give it to her. Case 79 died comatose, in about forty hours after the operation, which was performed at the Hospital of the University. There were no complications other than the long incision needed for the extraction of a large multilocular tumor, too solid to be reduced in size. There were from the first, coma and suppression of urine. At the autopsy the liver was found to be fatty, the kidneys greatly contracted, and the spleen hypertrophied and breaking down. Her advanced age and the carbolated spray had probably something to do with the unfortunate result. The death of Case 83 remains yet a mystery to me. The operation was performed at the hospital, and was unusually easy. The tumor consisted of a thick-walled, partly solid multilocular cyst of the left ovary, and was nourished more by the omentum, to which it was attached, than by a very slender and long pedicle. She did extremely well for six days; then acute mania set in, from which she died twenty-four hours later. The autopsy revealed no cause whatever for this unexpected death, and I am disposed to attribute it to embolism. She had multiple uterine fibroids, and one of them, as large as an apple and pedunculated, I removed, but I do not think this had anything to do with the result.

A few words about Case 70 are needed. At the time of the operation she was much emaciated; very feeble, and greatly distended by eighty pounds of fluid. The sac had hepatic, omental, intestinal, pelvic, and parietal adhesions, and she narrowly escaped dying on the table. For several days she lay in a critical condition; then she slowly began to mend. She was fairly convalescent when she became homesick, and on the eighteenth day after the operation insisted upon being taken to her home in Camden, New Jersey. A year later I learned that she died from "vomiting" fourteen days after her removal. She was a homœopath, and one of her reasons for going home was that she objected to our medicines.

The results of my cases are not as good as those of British ovariotomists; but these gentlemen do not publish their uncompleted operations, nor the cases on which they decline to operate. Without these data, no just estimate can be made of individual success. My statistics, however, compare very favorably with those of the Vienna General Hospital for 1881. During that year "ovariotomy was performed sixty-four times, with thirty-eight recoveries, twenty-five deaths, and one woman discharged with marasmus." [1]

The chief lessons which I have learned from my experience during the last year, are: First, to administer ether largely diluted with atmospheric air. Hitherto, I have, in common with most American surgeons, given this anæsthetic by a closed cone, in such a way that the patient breathed her own air over and over again. I am now disposed to think that this is a very unsafe mode, and that to it is due, in a large measure, the alarming prostration of the patient while undergoing the operation. For instance, among the twenty-five cases of last year, Cases 70, 71, and 82, presented such profound symptoms of shock, that the operation had to be suspended until hypodermic injections of brandy and of ether were made, and some degree of reaction had set in. In Cases 70 and 71, it was indeed with great difficulty that the women were kept from dying on the table; while Case 85 clearly died from œdema of the lungs. Now, I do not find such alarming symptoms referred to in any reports of cases by British operators. I am therefore forced to the conclusion, that either under the strain of rivalry they do not operate in very desperate cases, or their mode of administering anæsthetics is a safer one than ours. Fully impressed with this idea, I have lately been using Dr. Allis's improved inhaler, and have thus far found it to act promptly, safely, and economically.

My second lesson is not to include the recti muscles in the sutures which close the abdominal wound. In most cases of ovarian tumor, and especially in those in which the cysts are large, the recti muscles are so widely separated from one another, that they barely come into view, and are not likely to be included in the sutures. But in cases of small cysts, and especially of öophorectomy, the *linea alba*, being then a mere line, cannot always be closely followed by the knife, which is likely to go astray into the sheath of one of these muscles. To get back to the linea alba needs careful dissection, and into the more or less ragged wound thus made, the bellies of these muscles pout. The temptation is so strong to include them in the sutures, that I have hitherto done so. But, finding that abscesses are likely to form in the track of these sutures, I now exclude these muscles.

[1] MEDICAL NEWS, Dec. 30, 1882, p. 745.

THE ABRUS PRECATORIUS (JEQUIRITY) IN THE TREATMENT OF SOME DISEASES OF THE EYE.

BY U. H. BROWN, M.D.,
OF SYRACUSE, NEW YORK.

THE profession are indebted to that indefatigable worker and student, Dr. De Wecker, of Paris, for the introduction into ocular therapeutics of a remedy which has proved itself of great value in the treatment of some of the most intractable forms of eye disease, such as granular conjunctivitis, inveterate pannus, corneal ulcers, etc.

Jequirity, or gequirity, is a shrub, generally known under this name in the north of Brazil, of the class of the dicotyledons, and belongs to the vegetable family of the *Abrus* species.

According to Le Maout and Decaisne (*Traité général de botanique*), the little shrub is original of Africa and tropical Asia, and transplanted to South America. On the other hand, M. Mello e Oliveira, a Brazilian botanist, claims that it is indigenous to Brazil, and non-transplantable. It grows everywhere in Brazil, as well in the highlands as in the interior or on the coast, but is particularly abundant

in the province of Matto-Grasso, which lies between the basins of the Amazon and the Plata, and in the "midst of its virginal forests, where the hand of agriculture has never penetrated." The root is employed in all the torrid zones for the same use as liquorice. The seeds or beans are red, lustrous, irregularly spheroidal in shape, hilum black, and so hard that they are used for making collars and other ornaments. They are found in a great pod, an inch and a half in length, opening by two valves, and divided into as many cells as there are seeds.

The *Abrus precatorius* has been used for years in certain provinces of Brazil, empirically, as a remedy for "granulated eyes," and came to the notice of De Wecker through a patient who had been cured by its use.

De Wecker began his experiments at his clinique in Paris, and published the results in the *Annals D' Oculistique*, for August, 1882, and has followed it in the December number of the same journal with another article confirming his first experience with the drug.

In preparing the remedy for use, he follows the formula which is used in Brazil, viz., "Triturate 32 well-pulverized seeds, and macerate them twenty-four hours in 500 grammes of cold water. The following day add 500 grammes of hot water. Filter the liquid immediately after cooling."

The effect which is desired from the application of the drug is the excitation of a purulent inflammation of the conjunctiva of an intensity sufficient to destroy the granulations, such a result as is sought for by inoculations with gonorrhœal pus.

De Wecker thinks that jequirity develops a vegetable ferment upon the diseased conjunctiva, which prevents the evolution of new granulations, and is destructive to those already formed. And further, he concludes from his experiments:

"*First.*—That the lotion of the infusion of the seeds of jequirity produces a purulent ophthalmia of a croupous nature, of which one can regulate the intensity according to the number of applications made, and the strength of the remedy which is employed.

"*Second.*—That the cornea does not run the least risk during the development of the purulent condition, as it is only when the ophthalmia has been pushed to the point of a veritable diphtheria that this membrane shows a passing circumscribed desquamation.

"*Third.*—That jequirity ophthalmia *rapidly* cures granulations, and with infinitely less danger and trouble to the patient than inoculations with gonorrhœal pus, for the ophthalmia produced by jequirity disappears of itself in from eight to twelve days, without the intervention of any treatment, by simply confining the patient to a darkened room."

My experience with the drug confirms the report as regards its effect locally and constitutionally. Soon after the application of the jequirity lotion to the inverted lids, sensations of heat and pain are felt, attended with lachrymation; after the second and third applications, made at intervals of from four to six hours, a decided irritation of the ocular and palpebral conjunctiva is produced, followed within the next few hours by a purulent secretion, swelling of the eyelid, together with œdema of the conjunctiva; a false membrane of a whitish color forms upon the conjunctiva. Usually after four or five applications of the remedy a purulent ophthalmia is produced, with its accompanying constitutional symptoms, viz., feverishness, headache, constipation, etc. When the drug has only been pushed to the production of the membrane, these symptoms abate on the fifth day, and the discharge gradually diminishes and disappears on the ninth or tenth day.

That the intensity of the inflammation produced depends upon the strength of the infusion and the frequency of its application, is well illustrated by experiments recently made upon rabbits by Dr. Moura Brazil, of Rio Janeiro (*Annals D' Oculistique*, December, 1882). He employed an infusion of the strength of one gramme to 20 grammes of water, applying it directly to the animal's conjunctiva, and also bandaging the eye with it. The effects were severe from the first, and on the second day there was great œdema of the conjunctiva with violent inflammation, thick false membranes formed, and on the fourth day, the cornea became whitened and rough to the touch; there was a profuse purulent discharge; the lids became greatly swollen, and the parotid and submaxillary glands were greatly engorged, making it difficult for the animal to eat. On the fifth day the false membrane had disappeared, and the conjunctiva was coriaceous. Everything was done to combat the inflammation: cauterizations with argent. nit. (2 grammes to 100 of water); iced compresses of a solution of borate of soda (2 grammes); carbolic acid (50 cent.) in water (500 grammes), and all without benefit. The inflammation progressed; the cornea became sphacelous; the globe of the eye suppurated; the lids were gangrenous; the skin covering them fell off to a great extent, and the submaxillary gland suppurated. The poor victim of this experiment still lived.

That there is danger in the employment of the stronger infusions, is also shown in a little memoir upon the employment of jequirity, published in 1867, by Dr. Castro E. Silva, of Ceara, Brazil, in which he relates several disastrous cases of jequirity ophthalmia occurring in the provinces of Ceara and Piauhy, where the use of the drug is much abused. There one often sees violent inflammation of the lids which extends to the face, neck, and upper portion of the thorax, the submaxillary glands often taking on an intense inflammation, which ends in suppuration.

The popular lotion seems to be the curative one, as can be seen in the following cases in which I have employed it.

Case I.—C. T., aged twenty-four; machinist; came to the Eye and Ear Infirmary in November, 1882, suffering from dense pannus, with granulations of the left eye. The disease had been of three years' duration, and vision was reduced to perception of shadows. He had been treated for six months in Detroit and Milwaukee by oculists of repute, but with little benefit. I treated the case two months, employing the usual remedies; cupri sulph., argent. nit., and iodoform, but with no great

improvement. He was then admitted to the hospital, and the treatment with the infusion of jequirity was instituted; the effects following its use were the same as already described, and the patient was discharged on the thirtieth day from the commencement of the treatment, with V. $= \frac{20}{C}$, and able to read large print.

CASE II.—Hattie R., aged fifteen; trachoma of three years' duration, has been treated without success during the last ten months; the conjunctiva of both upper and lower lids was covered with large, easily bleeding granulations, separated by deep sulci; left cornea had a thick pannus; sight was reduced in left eye to perception of large objects. Upper half of right cornea was covered with a pannus, and in this eye sight $= \frac{20}{C}$. Jequirity treatment was begun January 10th; and on February 15th the patient left the hospital free of granulations, and the corneæ sufficiently clear to give V. L. $= \frac{20}{C}$, V. R. $= \frac{20}{XL}$.

CASE III.—Katie R., aged nine; inmate of orphan asylum. A case of intractable follicular conjunctivitis of both eyes of five months' standing. Corneæ vascular, V. R. $= \frac{20}{C}$, V. L. $= \frac{20}{CC}$. On the 12th of January, three applications of jequirity were made, and on the following day two more, which were sufficient to develop the purulence with the false membrane. The hypertrophied follicles became paler after the seventh day, and had disappeared altogether on the twenty-fourth day, when V. R. $= \frac{20}{L}$, V. L. $= \frac{20}{XL}$.

CASE IV.—A man, aged forty, came to the hospital in December, 1882, with a subacute vascular keratitis of the right eye, of three months' duration. The bloodvessels on cornea were large; opacity great; superficial marginal ulcer above; conjunctiva of upper lid much swollen, especially at retrotarsal fold. S. reduced to counting of fingers at ten inches. Was treated for one month with eserine, hot aromatic compresses, etc., but with only slight benefit. The jequirity treatment was instituted January 15, 1883, and at this date, one month later, the cornea has cleared so that he has V. $= \frac{20}{C}$.

NOTE.—The infusion should be prepared from fresh beans, as when old they lose their efficacy. Those which I used in the above cases were obtained from "The Pharmacie Robinet," 55 Rue Cherche-Midi, Paris.

UTERUS SEPTUS BI-COLLIS.

BY HOWARD A. KELLY, M.D.,
RESIDENT PHYSICIAN AT THE EPISCOPAL HOSPITAL, PHILADELPHIA.

J. K., a servant, born in Germany, thirty-six years of age, applied at the Episcopal Hospital on the ninth inst. for relief.

She complained of constant pain across the small of the back, following a fall last summer; she also gave a history of severe pains at every menstrual period since the first at fifteen years of age, although regular as to time, duration, and amount of discharge.

The vaginal canal, upon digital examination, is long, and up in the right-hand corner of the cul-de-sac, posteriorly, a small hard os is detected. The cervical canal can scarcely be felt. The fundus uteri is felt through the anterior vaginal wall above the os. No view of the os can be obtained by the shorter Goodell speculum, but while manipulating the instrument for a more satisfactory view, a fleshy column comes into view, lying close against the right vaginal wall. The general appearance of this column—long and narrow in the middle, with broader bases on the anterior and posterior walls, whose fibres arch outwards to the right and left—suggests its being a septum, which is then brought into view with the blade of the speculum on either side. The vaginal cul-de-sac is divided by this septum into two equal parts, having no inter-communication.

Further digital examination reveals at the bottom of each half, lying in the angle between the septum and the *posterior wall*, a small hard os. These are each readily brought into view and embraced by a Fergusson speculum of one-half inch calibre.

The external sexual organs are well developed. The hymen hangs in thick, rosy-red, fringe-like folds which meet in the centre of the canal, not, however, diminishing its calibre.

The free border of the septum lies two and three-eighths inches from the fourchette, just back of the well-marked rugæ vaginæ. It presents the appearance described. On its left border at about the middle hang several small papillary eminences. The septum measures one and three-eighths inch from its free border to the base, where it rounds off to either side to embrace each os.

The cervical canals appear to be well separated. The sound passes two and three-quarter inches anteriorly into each, and upon rotation reduces the flexion of the broad-bodied uterus.

Rectal examination adds nothing of interest.

Jan. 1–9.—Patient is now menstruating freely, and equally from each os; shreds of bloody tissue hanging out of the cervical canals.

She was examined once in Germany, per vaginam, by a physician, who remarked upon nothing unusual. She has never been examined in this country up to the present date. It is interesting to add that she has never experienced sexual desire.

The case has been seen by Dr. Hopkins and by Dr. Morris Lewis, chief of the ward, and it is through his kind permission that I am able to present this report.

HOSPITAL NOTES.

BOSTON CITY HOSPITAL.

Service of W. C. B. FIFIELD, M.D.

NON-UNION OF THE TIBIA AFTER OSTEOCLASIS; RESECTION AND WIRING OF THE BONE; SUCCESS.

(Reported by ROYAL WHITMAN, M.D., House Surgeon.)

THE patient, a girl, five years of age, entered the hospital June 13, 1882, with the following history:

Since birth her limbs had been slightly distorted, and about two years before her admission to the hospital, her mother, thinking that the deformity was increasing, had taken her to the Children's Hospital, where she was admitted on August 30, 1880. Examination showed more or less bowing of the arms and legs—otherwise the child appeared to be in good condition. Osteoclasis was then performed on the left tibia, which was fractured at about the junction of the lower and middle third. The leg was then straightened and placed in a plaster bandage. On October 10th, the right lower leg and right lower arm were also fractured and placed in stiff bandages. They united in good position in a few weeks. The left leg, however, did not unite firmly, and there was also a considerable projection forward of the tibia at the seat of fracture, and on March 24, 1881, it was again fractured at the point of partial union and the tendo Achillis was also cut. The leg was straightened and placed in a plaster bandage. On April 19th there was no formation of callus. May 24th, there was partial union, but with bowing forward of the tibia. She was then discharged from the hospital, and during the following summer was treated in its out-patient department, the leg being kept in stiff bandages. In November, 1881, she again entered the hospital, and during the following winter was treated with a steel support, an attempt being made to straighten the leg by pressure with pads. On February, 1882, there was no improvement, and she was discharged wearing the apparatus. From this time until she entered the City Hospital, there was no change in the condition of the limb. At the time of her admission, the examination showed the following results: The child was well nourished. Her limbs, other than the left leg, were quite straight, and presented no evidences of the previous operations.

There was a considerable bowing forward of the left tibia, and at the seat of the former operation there was considerable mobility. The child walked with a marked limp and the leg was considerably atrophied from disuse.

On June 13, 1882, Dr. Homans, refractured the leg at the point of non-union, and it was straightened and placed in a plaster bandage.

On July 9th, the plaster bandage was removed, but only a moderate amount of union was found to be present, and the leg showed a decided tendency to return to its former faulty position.

July 15th, Dr. Homans again broke down the adhesions between the extremities of the bones, and the leg was again placed in a stiff bandage. She was kept in bed until August 25th, when she was allowed to get up and to walk about with the leg still encased in the plaster bandage, in the hope that the irritation might cause a firmer callus.

On September 12th, the stiff bandage was removed and the leg was found to be in nearly the same condition as upon her entrance.

And taking into consideration the fact, that the child had been under treatment for more than two years without benefit, and as the leg was much atrophied from disuse, and as there seemed to be no prospect of any immediate improvement, it was decided that a more radical operation was justifiable, and, on October 20, 1882, Dr. Fifield, with full antiseptic precautions, made an incision over the point of non-union; the thickened periosteum was separated from the bone, which was refractured. The bone at this point was found to be in a state resembling chronic inflammation, the bone being thickened and the medullary canal almost obliterated. A thin wedge-shaped portion of bone—the base of which was anterior—was sawed from either extremity of the bones in order to counteract the bowing forward. The extremities of the bone were then firmly united by a strong silver wire. The periosteum was then brought over the bone and held in position by fine catgut sutures. The skin was brought together with several silk sutures. A Lister dressing was applied and the leg was placed in a post-plaster splint. No constitutional disturbance followed the operation. The dressing was changed three days later and the stitches were removed. The silver wire was removed on December 7th, at which time there was firm union, and the leg was in good position. December 25th, the child walked well with slight limp. She was discharged on February 14, 1883. At this time she still retained a slight limp, which was disappearing, the leg was increasing in size, and there was no tendency toward bending at the point of fracture.

This case is interesting, as showing a possible result after the operation of osteoclasis, and also interesting as showing the rapid recovery of the child after the comparatively severe operation.

MEDICAL PROGRESS.

Action of Narcotics.—Brown-Séquard thinks that narcotics exercise a sedative effect only by producing *cerebral inhibition*. Opium, for example, produces sleep, not because it possesses the power of producing sleep, but because it is an energetic excitant of the sensory nerves, from which the clinical fact appears that it is not only necessary to consider beforehand the dose, but also the place of application. In fact, a small quantity of morphine injected into the neck, at the level of the superior laryngeal nerves, produces general analgesia much more effectually than if injected at some other point. In this case the local action of morphine is comparable to that of carbonic acid injected into the larynx. It is doubtless to this same mechanism, excitation of the sensitive nerves, that the cessation of violent attacks of cough is to be explained, after subcutaneous injection of pure water into the front part of the neck.—*Le Progrès Méd.*, March 24, 1883.

Calcification of the Kidneys in Acute Corrosive Sublimate Poisoning.—MM. J. L. Prevost and G. Frutinger have concluded, from numerous experiments on mammalians, with corrosive sublimate, that a true calcification of the kidneys takes place, there being at the same time a decalcification of the bones, so great in two cases, that the epiphyses were movable on the diaphyses. It is often so marked that the kidneys seem petrified. Large doses produced it more readily than a succession of small doses.—*Revue Internat. des Sciences*, February 15, 1883.

Abscess of the Frontal Sinus; Recovery.—This case occurred in the service of M. Marc Sée, at the Municipal Health Hospital, Paris. The patient, æt. 64, had a small tumor, situated at the internal part of the superciliary arch, on the left side. For fifteen years she has been subject to colds in the head, and lately the nasal discharge has had a fetid odor. There is no evidence of scrofula. In September, 1882, vision on the left side became obscure. She suffered, after that, with frontal and temporal headache, and, at the same time, noticed a small tumor, which disappeared on pressure. M. Sée diagnosticated abscess of the frontal sinus, and operated on November 17. He made a small incision parallel to the arch of the brow, and a little above it. The pus having escaped, he scraped the sides of the cavity, and put in two small balls of charpie soaked in chloride of zinc solution, and dressed the wound antiseptically. The charpie balls were retained two days, and then carbolic acid solution injections were made, morning and evening,

for several days. When last seen, January 15, 1883, the woman was entirely well. Abscess of the frontal sinuses is a rare affection, more especially if non-traumatic, or without syphilitic antecedents. — *L' Union Méd.*, March 13, 1883.

Operation for Detached Retina.—Dr. J. R. Wolfe, F.R.C.S.E., Senior Surgeon to the Glasgow Ophthalmic Institution, advises that in cases of detachment of the retina, a vertical slit be made with scissors into the conjunctiva and subconjunctival tissue, laying bare the sclerotic at a point corresponding to the site of the detachment. The lips of the wound are separated by two small strabismus hooks, and the assistant steadily maintains the position of the eyeball, to prevent the exposed portion of the sclerotic from shifting; the sclerotome is then introduced into the sac. The incision through the sclerotic is made obliquely, in such a manner that the edges of the scleral wound should overlap each other when the instrument is withdrawn, and not remain gaping. Gentle pressure is made on the eyeball in the track of the receding lance by means of a fine spatula. The lips of the external wound are brought together with one or two fine silk ligatures, and both eyes are strapped with court-plaster. The patient is kept in bed, in a dark room for three days. The plaster and ligatures are removed on the sixth day, and the eye is gradually accustomed to the light. On the eighth day the result may be tested. Before resorting to the operation, says Dr. Wolfe, we must ascertain (1) that there is no opacity or softening of the vitreous, or at any rate, if present, that it is not general, but confined to the region of the detachment; (2) that the retina is healthy; (3) that the effusion is purely serous; (4) the exact site of the detachment. He reports five cases in which this operation has been successful.—*Practitioner*, March, 1883.

Elongation of Nerves in Ataxics.—M. Lépine has reported to the Society of Biology his results from subcutaneous elongation of the sciatic nerve in a number of cases. After having tried unsuccessfully Langenbeck's and Débove's operations, he used the following: The lower limb being extended, the thigh was slowly and forcibly flexed on the trunk; this manœuvre being repeated every day for several weeks. After a time, modifications of sensibility and increased temperature are observed in the limb operated upon, and sometimes in the other. The patient complained of formications in the foot and leg, and there was marked diminution of the tabetic phenomena, shooting pains, and motor incoördination. There were no injurious effects.—*Le Progrès Méd.*, March 24, 1883.

Gastrostomy.—M. Tillaux reported to the *Societé de Chirurgie*, the case of a man, æt. fifty-two, without syphilitic history, no local phlegmasia from the ingestion of corrosive liquids, who entered his service in 1881, with a very small fibrous stenosis seated about seven inches below the cricoid, and almost one-half inch wide. He left the hospital, and reëntered in February, 1882; was pale and dysphagic. M. Tillaux tried, once only, to pass a very small olive-point, and failing, decided to perform gastrostomy. The greater curvature of the stomach did not extend beyond a horizontal line drawn between the cartilages of the ninth and tenth ribs. If, from that line one is drawn on the right side along the anterior border of the liver, and another on the left following the line of the costal cartilages, they will bound a triangle corresponding to the seat of the stomach. M. Tillaux made an incision parallel to the costal border, about two and a half inches long, not passing beyond the horizontal line described above. Seventeen sutures were made, and the wound closed. The patient did well until the twelfth day, when he refused to eat, gradually became worse, and died on the forty-seventh day. At the autopsy fibrous contractions and solid cicatricial adherences existed between the stomach and the abdominal wall.—*Journ. de Méd de Paris*, March 24, 1883.

Nitrite of Sodium in Angina Pectoris.—Dr. Matthew Hay, Demonstrator of Materia Medica in the University of Edinburgh, has used the nitrite of sodium very satisfactorily in a case of angina pectoris. So far as he is aware, this is the first case of angina pectoris in which a simple nitrite has been used. He thinks that it is as active and reliable as nitrite of amyl, or nitro-glycerine, at the same time possessing distinct advantages over either of these, notably in producing, in therapeutic doses, no disagreeable general effects—headache, giddiness, and even partial collapse. The objection to it is its tendency, in large doses, to produce eructations of nitrous acid gas, which, however, does not occur when small doses are administered. The formula used by Dr. Hay was: ℞. Sodii Nitrit., ʒss; Aquæ, ad ʒxij. Solv. S. Dose, one or two teaspoonsful.—*Practitioner*, March, 1883.

Role of the Lymphatic Vessels in Pathological Phenomena.—M. A. Guérin has made this the subject of a paper read before the *Acad. des Sciences*. He shows, by a series of experiments, in accord with the views of Sappey but contrary to the opinion of some microscopists, that the lymphatics anastomose with the terminal arterial ramifications, and that a liquid, analogous to the serum of the blood, can pass directly from the arterial into the lymphatic system. This communication of the two systems is especially important, as explaining certain pathological phenomena. It seems from this that it is the invasion of the lymphatic territory by blood globules which constitutes the first phenomena of suppuration. Thus, when the pleura is inflamed, the lymphatics are quickly obliterated. It is by these numerous networks covering the surface of the lungs that the phenomena commence, and one attempts in vain to inject these on the lung of a person recently dead of pleurisy. If the lymphatics are also the agents of absorption of the pleuritic effusion, it is easily seen that this absorption cannot take place while they remain impervious; and it is doubtless on this account that we see pleuritic effusions resist the most energetic treatment, and then disappear in a few days when the absorption vessels become pervious.—*Révue Scientifique*, March 24, 1883.

Uræmia of Hepatic Origin.—M. Débove read a note before the *Soc. Méd. des Hôp.* on this subject. According to Brouardel, the urea is diminished in hepatic disorders. Débove's researches confirm this, though he interprets the fact differently from Brouardel. The diminution of the amount of urea may be explained by two theories: some difficulty of excretion of urea in the kidney, or some fault of formation in the liver. The latter theory has been adopted by Brouardel and most other authors. To prove it, he has attempted to show that the blood-urea (as opposed to the urine-urea) is equally diminished, and consequently the liver makes a smaller quantity of it; but Débove's experiments do not confirm this. As a result of his researches, Débove thinks that, from a therapeutic point of view, there is indication to determine polyuria in patients affected with grave icterus, in order to facilitate the elimination of extractive matters, such as have been recognized by Brouardel, A. Robin, Mossé. He thinks that this should be done in all cases of icterus.—*Journ. de Méd. de Paris*, March 24, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, APRIL 14, 1883.

KOCH AND HIS AMERICAN CRITICS.

At the end of a year from the reading of his original paper on the Etiology of Tuberculosis, Koch reappears in print (*Deutsche medizinische Wochenschr.*, March 7th) in reply to his critics. The publications, he says, which do not confirm his views are so few that he might well pass them over in silence, especially as they all show for their authors either a complete or very considerable ignorance of bacteria-investigations, or incapacity for estimating the relations of pathogenetic bacteria to infectious diseases. Altogether without previous knowledge or experience in easier tasks, they have undertaken this difficult question; hence it is not to be wondered at that they have produced such defective work.

Taking up, first, American critics, Dr. Koch might have spared himself any allusion to Ephraim Cutter and Rollin R. Gregg, whose criticisms betray their incompetency to discuss the question, and in this country, at least, fail to attract any serious attention. Schmidt's unfortunate error with his fat-crystals is only saved from being equally discreditable to American investigation by the manliness with which the New Orleans histologist admits his mistake.

"An equally capable microscopist with Schmidt," says Koch, "appears to be Formad." Notwithstanding this, he fails to discover the bacillus in the sputum of a number of phthisical patients, although extensive destruction and cheesy alteration had taken place in the lungs. Besides, he denies that the bacilli of tuberculosis present any peculiarities in their behavior towards staining solutions, as contrasted with other bacteria. "Whence there can be no doubt," says Koch, "that Formad has not found the tubercle bacillus at all;" and, finally, "that Formad's judgment as to the significance of tubercle-bacilli is not worthy of attention until he has learned to recognize them with certainty; until he has made himself familiar with current literature, and especially the intra-ocular inoculations of Cohnheim and Salomonsen, of Hänsell, Schuchardt, Baumgarten, and Damsch; and until he has so far progressed in the experimental technique that his animals inoculated with wood, glass, and metal no longer die of tuberculosis; or, at least, until he can distinguish whether an animal has died spontaneously ill of inoculation-tuberculosis."

In the charge of incompetence against Formad, involved in these statements, Koch goes too far. For any one who reads thoroughly Formad's paper, cannot lay it aside without feeling that its author knows what he is talking about, whatever may be his errors; and the assertion that he cannot recognize the tubercle-bacillus when treated according to Koch's own method is a gratuitous assumption. This being the case, it is hardly likely that Koch will accept the testimony of those acknowledged in this country to be experienced microscopists, who, familiar with Dr. Whittaker's specimens fresh from the laboratory of Koch, after examining the preparations of Formad alongside of those of Schmidt, promptly said of the former, these are the real tubercle-bacilli, and of the latter, these are fat-crystals.

Formad does not deny that the bacillus is found in the sputum of phthisis, as Koch would have us infer. On the other hand, Formad says, "There is consequently no doubt of the existence of this organism in the sputa of patients suffering from this disease." He only says that, "in examining the sputa of a number of undoubted cases of pulmonary phthisis from the Philadelphia Hospital, I was unable to detect the bacillus *in a certain number*," and not *in a number of cases*, as Koch puts it.

As to the morphology of tubercle-bacilli, and their behavior with staining fluids, we have a direct issue between the two observers, in the decision of which the greater experience of Koch must be allowed a proportionate weight; although Spina, who must also be acknowledged to be a less expert mycologist, agrees with Formad. It is, however, an interesting fact that in both instances (the only ones so far as we know) in which the experiments of Koch have been systematically repeated by pathologists, their conclusions have been contrary to those of Koch. For although Spina's reputation is chiefly as a histologist, it is impossible for him to have been working under Stricker's eyes for thirteen years without becoming also a pathologist. It is a nota-

ble fact, too, which Koch mentions, and as to which he expresses himself disappointed, that his results have been tested by few pathological anatomists upon whose territory they more especially trench, and that his investigations have rather attracted the attention of clinicians.

It is true that Formad makes no reference to the important intra-ocular (iris) inoculations of Cohnheim and others above referred to. Koch's adherents lay particular stress upon what they term Cohnheim's conversion to Koch's views through these intra-ocular inoculations. But they overlook the fact that Cohnheim's two series of experiments, viz., the first proving the non-infectiousness of tuberculosis and the second denying it, were not identical; the first being inoculations with indifferent substances into the *peritoneum*, and the second into the *eye*.

In the matter of tuberculosis being produced by the introduction of indifferent substances—glass, wood, and metal—Koch says Formad is behind the times, and that he holds the position occupied in Waldenburg's time, fifteen years ago, a position which has been overthrown by Cohnheim and Salomonsen's results. But Formad's voice is not the only one which, at the present day, sustains this old-fashioned doctrine. For not only Spina, but also Stricker, reaffirms so recently as March 16, 1883 (see *Wiener medizinische Presse*, March 18th), that "one may, with numerous indifferent substances, produce as true a tubercle as by means of tuberculous material taken from human lung." Stricker also states in the same connection that he "has tested and approved the assertion of Spina, founded upon a historical and experimental basis, that the inoculation-experiments of Dr. R. Koch, of Berlin, have not, in the least degree, contributed to prove the contagiousness of tuberculosis."

Formad's position that tuberculosis depends upon scrofulosis, and that there are scrofulous animals which may be inoculated with tuberculosis, and non-scrofulous which may not be inoculated, Koch meets by asserting that cats, which Formad places in his non-scrofulous category, are in his hands easily inoculable. Here again is fact against fact, assertion against assertion, and the question must be settled by third parties. At the same time, Koch practically admits such a subdivision exists when he says that white mice and dogs are both infected with difficulty, while Guinea-pigs and rabbits are infected with ease.

Koch fails to answer Formad's question why he invariably inoculated into the peritoneal cavity when he experimented with cats, dogs, and rats, and why he inoculated indiscriminately into any part of the body, animals like the Guinea-pig and rabbit, well known to possess a peculiarly scrofulous tendency; for it has been repeatedly shown by the experiments even of Cohnheim, as well as of Stricker and others, that the introduction of indifferent substances into the peritoneal cavity of non-scrofulous animals is followed by true tuberculosis, while the same substances introduced under the skin of these animals is totally without effect. A parallel to this is found in man, in the clinical fact that a pleurisy may terminate in a miliary tuberculosis in one in whom a phthisical history cannot be traced.

Of Sternberg, Koch disposes summarily by saying that because he could not find the bacilli he denied their existence, and it is to be hoped that in the mean time he has discovered his error.

So much for American literature. In our next issue we will consider Koch's German critics.

FAT-CRYSTALS IN THE URINE.

THE much-disputed question as to whether fat-crystals ever appear in urine would seem to have been settled by the observations of PH. KNOLL, who found (*Centralbl. für die med. Wiss.*, February 3d, from *Prag. Zeitsch. f. Heilk.*, iii. s. 148), in the freshly passed urine of a patient dying of subacute chronic nephritis with uræmic symptoms, a number of spherical, oval, cylindrical, and sometimes peculiarly constricted cells, filled with smaller and larger drops, whose fatty nature was shown in their behavior by transmitted, reflected, and polarized light, as well as by osmic acid staining. Many of these cells were beset with regular rhombic, pointed and delicately contoured plates, which, when seen on their edges, appeared like needles. They were soluble in ether, but unaffected by acids and alkalies. The urine was turbid, and contained casts, numerous white and some red corpuscles.

Microscopic examination of sections of the large white kidney derived from this case, revealed almost the same crystals—fewer of the long plates, but more numerous druses of smaller plates and needles. They were less numerous in the medulla than in the cortex, and in the latter situation they were present more particularly in the medullary rays; scarcely at all in the glomerules, and only occasionally in the interstitial tissue.

THE AMENDED BILL FOR THE LEGAL PROTECTION OF THE INSANE.

IN our issue for March 17th, we alluded to the bill relating to the above subject, now before the Legislature of Pennsylvania, commending most of its provisions and suggesting some important amendments. The bill as amended by a conference of those interested in the subject is now before us, and while in some respects improved, it still lacks the most important provisions we alluded to; and in some particulars is worse than it was before, for the

changes are in the direction of *less* rather than greater protection of the alleged insane.

Very properly, the State Board of Public Charities has been placed in a more intimate and authoritative relation to the matter. But why on general principles any established hospitals should be exempted from taking out a license, we fail to see. True, the control over such excepted hospitals by visitation and inspection is retained, but the chief means of securing their proper administration is swept away. In the case of licensed institutions, public and private, the Board may revoke the license if they find sufficient cause so to do, but such control is denied them in the case of the excepted hospitals. If this be on legal grounds as an interference with vested rights, we suppose it must be submitted to, but it is none the less to be deplored. No institution ought to be exempted from such control; and any institution that objects to it is *ipso facto* the more to be suspected.

Again, the provision for visits of inspection and investigation once a month is omitted. While an "effectual visitation" is prescribed, it is left to the Board to determine how frequent this shall be. The number of persons allowed to visit an alleged lunatic is no longer indeterminate, but is cut down to "two proper persons," and the report on each case to the Board is to be made once in six months, instead of once in three.

Correspondence is simply to be "stamped and mailed," the word "daily" being omitted—a most important omission; and no provision is made, as in the English law, for forwarding indecent or improper communications to the Board, instead of to the person addressed.

The Committee in Lunacy, of which but one member is necessarily a doctor, still has power of summary discharge; and the medical officer of the institution must make his diagnosis within twenty-four hours; and voluntary patients are still not allowed to enter for a longer period than seven days; all of them defects which we previously pointed out.

We earnestly hope that these suggestions will receive consideration before the bill is put upon its final passage.

THE DEATH OF SURGEON-GENERAL BARNES.

We print elsewhere an obituary notice of General Joseph K. Barnes, late Surgeon-General U.S.A., a physician whose career has been, as truly stated in the General Order announcing his death, "one of honor to himself, and of great service to his country."

It is largely due to his personal influence and administrative ability that we possess the *Medical and Surgical History of the War*, the Army Medical Museum, and the invaluable Medical Library of the Surgeon-General's Office.

The secret of his success is an open one, yet it is one which comparatively few can grasp and apply; it consisted in quick perception in selecting the right men for different kinds of work, in giving the men thus selected ample powers and responsibility, and allowing them full credit for the results.

He did not try to supervise all the details of the work of his department, a mistake which too many bureau officers are apt to make, but gave each of the officers under him an opportunity to develop his work in his own way, subject of course to the approval of his chief.

He had no thirst for personal notoriety, and his subordinates felt that while they would be held responsible for the completeness and correctness of their work, they might be sure of his support so long as that work was well done.

Under his administration the Medical Department of the United States Army has become the best organized and best supplied of any similar department in the world; and the satisfactory working of the machinery is best shown by the fact that upon his retirement it went on without a jar.

The medical profession of this country owes him a debt of gratitude for the work done for it under his direction; and although he was neither a writer nor a teacher, his name will live in the annals of medicine of this country as that of one who made substantial contributions to its advancement.

THE NATIONAL MEDICAL LIBRARY.

The letter from our special correspondent at Washington, which appears in another column, brings up a matter which is of great interest and importance to the medical profession of this country, and concerning which it is time that some systematic action was taken.

The experience of the last session of Congress shows that our Representatives and Senators will give heed to the wishes of the medical profession of the country, when these are tolerably unanimous and clearly expressed. There can be no doubt that the physicians of the United States, with scarcely an exception, desire that the library of the Surgeon-General's Office should remain under its present management, and would regard its transfer to and merging with the general library of the Nation as a calamity.

Let it be considered as the medical section of the National Library, let the number of volumes it contains be counted as part of the National Library, but let it be kept in connection with the medical museum, which naturally belongs to it and has special need of it, and under the expert management which has made it what it is.

What the library needs, and what the medical profession of this country should strive both individually and collectively to secure for it, are the following:

1. A commodious fire-proof building to contain the library, museum, and medical records.

2. An increase of the annual appropriation for the library, so that it shall be able to obtain every new medical book, pamphlet, journal, or transaction from all countries as soon as published, and shall also have some funds to complete its collection of old books as opportunity offers. The amount necessary for this purpose is estimated by the librarian to be $10,000 a year, independent of the amount necessary for the museum, and this estimate appears to us to be moderate and reasonable.

3. Authority to complete and print the *Index Catalogue*.

We commend this matter to the attention of the American Medical Association at its next meeting. It ought to have a Standing Committee to look after the interests of the medical profession in this respect, and to see to it—first, that our National Medical library is properly managed; and second, that so long as it is properly managed it shall not be swallowed by an ambitious librarian who knows nothing of medical matters, nor be crippled through mistaken ideas of economy by reduction of its appropriations, nor be left in a crowded and insecure building as it is at present.

A POOR PAYMASTER.

WE have often been impressed with the disproportion between the amounts paid to lawyers and doctors for professional services. No better illustration of this can be found than in the payment of the lawyers in the Star Route Trials, and the doctors who so intelligently served the government in the Garfield and Guiteau cases. We have already referred to the indignities heaped upon our profession in connection with these cases, and it only remains for us to condemn the carelessness and disinclination of the government officials to assume any responsibility in the payment of medical men who are engaged.

In the case of President Garfield we were humiliated to find that the nurse was paid almost as much as either Dr. Agnew or Dr. Hamilton. In the Guiteau case the comparison is almost as bad. With the exception of two or three favored medical men, the large number of distinguished experts summoned from all parts of the country received but twenty-five dollars a day. The personal loss to them was in some cases very great. One of these gentlemen by his enforced absence, we are informed, lost over two thousand dollars from his professional income, and another who was under engagement to deliver a course of medical lectures, was out of pocket to the extent of six hundred dollars. Other experts were equally unfortunate.

In this case the bills were referred to the District Attorney, Colonel Corkhill, for adjustment, and when it is stated that the compensation given for an equal amount of labor varied from $2,000 to $600, and that a local physician, who was on the stand not over ten minutes, received $200, the basis on which the compensation was calculated is difficult to understand.

In future we advise every medical man engaged by the Government to make his terms before-hand, or not to go to Washington at all.

We are in receipt of a letter from E. H. Hyatt, M.D., "Member of Faculty and Board of Trustees" of the Columbus Medical College, of Ohio, requesting us to publish "the action of the Illinois State Board" in the matter of the alleged irregularities of the Columbus Medical College, and so much of his letter "as will explain the causes which led to the investigation by the said Board." We have already, in our issue of March 3d, published these causes, which were charges by the West Virginia State Board of Health against the Columbus Medical College for the issuing of the Dent diploma, the circumstances of which were so recently narrated in our columns as not to require repetition. In the same issue we criticised the Illinois State Board, for not having mentioned this complaint in its published proceedings. We thought its action, when considered in connection with the recent accession to office of Gov. Hamilton, the nephew of Dr. J. W. Hamilton, the Dean of the Columbus Medical College, was calculated to place the Illinois Board in an equivocal position.

It seems that these charges were presented to the Illinois Board, and, two members of the Faculty of Columbus College being present, it was resolved, "that, while said College committed an irregularity in granting a diploma to A. M. Dent, that irregularity does not seem to warrant this Board in refusing to recognize other diplomas of said College." This can scarcely be considered as much of an endorsement of the Columbus Medical College, and it certainly does not alter the situation in unprejudiced eyes. The reputation of a medical college is not to be made or destroyed by resolutions of State boards of health. If a good reputation is desired, the only method to secure it is to adopt proper regulations as to curriculum, duration of study, and method of examination, and to live up to them. The publication of resolutions of the kind adopted by the Illinois State Board, which advertise the college while they condone its faults, will have but little weight with the community.

The New Code Controversy has broken out in New York with renewed vigor, as will be seen on reference to another column. The adherents of the National Code have awakened from their apathy, and the advocates of the New Code are aroused by the adverse vote at the late meeting of the New York County Medical Society. Both sides are rapidly organizing for a vigorous contest in the State Society next February. In the mean time, circulars are being distributed, and pledges received, and the issue is becoming sharply defined all over the State.

REVIEWS.

Quain's Elements of Anatomy. Edited by Allen Thomson, M.D., D.C.L., LL.D., F.R.S., Edward A. Schafer, F.R.S., and George Dancer Thane. Ninth edition, 8vo. 2 vols., pp. xiii. 748 and ix. 947. New York: Wm. Wood & Co., 1882.

It would be difficult to find just the counterpart to "Quain's Anatomy," as to age, authority, popularity, and completeness. Nine editions are rarely seen on either side of the water, at least in scientific works, and the two portly volumes which now make up this valuable work, are at once a witness to the extent of the Science of Anatomy and the thoroughness with which it is here treated.

The student will get not only a full knowledge of gross or macroscopic anatomy, but will also obtain a sufficient knowledge of microscopic anatomy as well, together with pretty full outlines of embryology, a department of which, in general, the profession is far too ignorant. Variations of structure, and superficial anatomy also are treated quite freely.

The editors are to be congratulated upon the admirable manner in which they have accomplished their work. Both letter-press and illustrations are good. Though bearing an American imprint, the work, save the title-page, is English.

SOCIETY PROCEEDINGS.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Stated Meeting, April 3, 1883.

The President, Alfred Stillé, M.D., in the Chair.

Dr. Wm. Barton Hopkins presented a report of a

CASE OF RESECTION OF THE RADIUS PERFORMED BY DR. JOHN RHEA BARTON, IN 1828.

This patient came under observation a month ago, at the Episcopal Hospital, where she came with her son, who had received an injury of the head.

The account which she gives of an operation performed upon her, fifty-four years ago, by Dr. John Rhea Barton, is as follows:

She says that when she was ten years of age she was taken to the Pennsylvania Hospital, for a disease of the forearm, which, it was thought, followed a sprain of the wrist. Dr. Barton placed her arm upon a table, and, with an instrument which cut at both ends, made an incision, and by scraping and cutting removed a long piece of bone full of small holes, like a honeycomb, and containing a large cavity in its centre. He told the students present at the operation that he did not expect new bone to form, but that a gristle-like substance would take its place. She remained in the hospital until the autumn, and in a few months after her discharge regained to a great extent the use of her hand.

In studying the condition of the parts as they now present themselves it will be of interest to note the main causes which have brought about the usefulness of the hand, the changes in position and function of the parts not involved in former disease, incident to the removal of so important a structure as the entire or almost entire diaphysis of the radius, and the influence these alterations have had upon the growth and development of the bones and soft parts. The usefulness of the hand would seem to depend not only upon the preservation of the upper and lower epiphyses of the radius, the former through probable extension of the periosteum giving attachment to the biceps muscle, and the latter to the long supinator, but also upon the strong healthy character assumed by the skin investing the lower end of the ulna. This skin cap is the principal antagonist to the action of the muscles of the forearm, and if from constant pressure against the bone it had become thin and tender, as it very likely would have done, without the intervention of a bursal sac, every movement of these muscles would have caused pain, and the hand would have become almost useless.

The skin has, of course, yielded to a considerable extent, and the hand has, therefore, been gradually dragged up the forearm. The thumb from the loss of the origin of its long flexor, has become feeble and disused. The ulna has been made an active agent in support, and having lost its styloid process, presumably by absorption, the lower end has assumed a smooth knob-like appearance.

The growth of the sound bones has been comparatively little arrested, this being evidence that active work was performed by the hand during the growing years, which succeeded the operation. The humeri are the same length. The right ulna is one and a quarter inch shorter than the left. Part of this difference must be accounted for, however, by the absence of the styloid process, and part may also be due to a somewhat deficient development of the whole lower epiphysis in length, though not in breadth, as it is full and broad.

From measurements made of the ulna in connection with this case, the average length of the bone in females at the age of ten years is about seven and a half inches. In this case it is ten and a quarter inches upon the left side, and nine upon the right. The difference in the circumference in the middle of the arms is three-quarters of an inch; in the middle of the forearms, two inches; and of the hands, one inch; all in favor of the left or sound side.

The hand is set in an everted position well up the forearm, the tip of the middle finger being four inches and a quarter nearer the elbow than upon the left side. Although thus distorted and so loosely attached that it can be brought at right angles with the line of the ulna, it is remarkably strong, and with it she is capable of executing almost any movement.

Articulated with the carpus is felt the lower end of the radius. In its proper place the head of the radius may also be felt, continuous with which, and extending down the forearm nearly to the hand is a prolongation of fibro-cartilage, occupying the site of the excised bone.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, April 5, 1883.

The President, Fordyce Barker, M.D., LL.D., in the Chair.

After the reading and acceptance of various reports, Dr. Edward L. Keyes read a memoir upon his late

friend and teacher, WILLIAM H. VAN BUREN, M.D., LL.D.

Resolutions commemorative of the life, character, and death of Dr. Van Buren, and expressing deep sympathy with his bereaved family and friends, were drawn up by Dr. Austin Flint, Sr., and read by Dr. Austin Flint, Jr. These were seconded in a few well-chosen words, by Dr. Alfred C. Post, in response to a call from the Chair, and were unanimously adopted by the Academy.

The paper of the evening was by DR. BEVERLY ROBINSON, entitled

A CLINICAL STUDY OF THE ACTION AND USES OF CAFFEINE AND CONVALLARIA MAIALIS AS CARDIAC TONICS.

Until very lately, many of us were accustomed to regard digitalis as the essential, nay, almost the only real stimulant or tonic of the heart. True it is, we consider alcohol a powerful stimulant, and incidentally recognize that it gives the heart renewed power.

In ether and ammonia, we have also diffusible stimulants of considerable value, but their action is evanescent, and is not to be relied on if a continued or specific effect upon cardiac contractability is required.

In iron, quinine, and nux vomica, or its alkaloid strychnine, we have three very powerful corroborants. They restore appetite, make blood of better quality, add to muscular vigor, and rehabilitate, in a notable degree, the general system.

In coca, also, we have a powerful stimulant to the economy, that frequently will strengthen or give tone to the nerves in a rapid manner, that no other drug with which the author of the paper was familiar, can accomplish.

In belladonna we have the only drug which has hitherto taken the place, even in a moderate degree, of digitalis in its direct tranquilizing, and at the same time, strengthening, effect upon the heart. But belladonna appears to influence especially the cardiac plexuses and intra-cardiac ganglia, and to give immediate power to cardiac muscular fibres, as digitalis does.

Within the past year, two new drugs have claimed our attention as cardiac tonics: caffeine; and *Convallaria maialis*, or its glucoside, convallamaria. The object of the paper was to present what was actually known in regard to the nature, action, and uses of these agents, and also to accompany this with records of some personal cases, and the obvious deductions which can be made therefrom.

Caffeine, or citrate of caffeine, as it is improperly termed, is no new remedy, but not until after the labors of Gubler and other therapeutists was the attention of the medical profession specially directed to it as a cardiac tonic and regulator. Over digitalis it has certain evident advantages: 1. It has no tendency to cumulate in the economy, and hence to occasion poisoning effects. 2. It acts with greater rapidity than digitalis. In cases of asystolism when life is imminently endangered, this property may be of great value. 3. It rarely or never disagrees with the stomach. Four illustrative cases occurring in the practice of Dr. Robinson were then cited in detail.

The second part of the paper was devoted to the Lily of the Valley, or *Convallaria maialis*. This drug had been known for many years, especially its purgative quality, which was similar to aloes and scammony. The conclusion of Ott, in his investigations upon the physiological action of *Convallaria maialis*, were given in full, together with a synopsis of the views of the principal previous writers on the subject. Dr. Robinson then detailed his personal experience with the drug as a cardiac tonic, and gave the detailed histories of eight cases in which cardiac debility was a marked symptom.

Convallaria, possibly, was a stimulator of the cardiac muscles in its first period of action, whilst its after-effect may become of a paralytic order. Further, it is, after the manner of digitalis, a stimulator of the medullary inhibitory centres. In this latter action, no doubt, resides its special power to control dyspnœa and the symptoms of purely functional heart disorder, particularly paroxysmal palpitation and rapid and irregular heart action dependent upon debility (Trideau). It was further probable that *Convallaria maialis* is more potent in its action upon the pneumogastric trunks than it is in its direct influence over the cardiac muscular fibre.

A summary of cases seemed to show:

1. In caffeine and convallaria we have two efficient heart tonics.
2. Diuretic action of caffeine is more marked than that of convallaria.
3. Convallaria is well borne by the stomach of most patients suffering with chronic cardiac disorders.
4. When not well supported, rejection of medicine by the stomach is probably due to the uræmic condition already commencing.
5. As cardiac tonics, it is difficult, as yet, to assign a decided superiority to either of these drugs, they both giving increased cardiac power.
6. Cumulative effects do not occur from their continued use during a period of ten days or more.
7. Their power of restoring the rhythm to the cardiac pulsations and increasing the bulk of urine is not equal to that of the infusion of digitalis.
8. In the latter drug we have still the most efficient heart tonic and regulator which has been discovered.
9. Digitalis is a more powerful diuretic than caffeine.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, April 5, 1883.

THE PRESIDENT, R. A. CLEEMANN, M.D., IN THE CHAIR.

DR. W. GOODELL exhibited some

CALCAREOUS PARTICLES PASSED PER VAGINAM.

The previous history had been that of menorrhagia, and multiple fibroids were found in the womb. One of these fibroids had evidently taken on calcareous degeneration, and had subsequently broken down and discharged these fragments into the uterine cavity. He stated that these particles were not true bone, but merely the product of a disorderly deposit of lime, which possessed none of the osseous elements, not even cartilage-corpuscles. This calcareous degeneration tends to cure the disease by breaking off the vascular filaments of attachment and lessening the nutrition of the fibroid. In one instance, the specimen of which is now in the Museum of the University of Pennsylvania, he had seen three fibroids wholly converted into stone. These stones were, however, very light, and not like those of the bladder. It was the expulsion *per vaginam* of these uterine calculi which had greatly puzzled the older anatomists.

DR. GOODELL also exhibited two calculi, and related the following histories of two cases of

STONE IN THE FEMALE BLADDER ASSOCIATED WITH FISTULOUS CONNECTION WITH THE BOWELS.

The first case was that of a patient of Dr. C. A. McCall, who sent her to him in October, 1881. For the preceding four years she had suffered very much from vesical tenesmus; she frequently broke wind *per urethram*, and often passed through the same channel the seeds of raspberries, of tomatoes, and of pears. A year before Dr. Goodell saw her, she had voided a great deal of her urine per rectum for several weeks.

Dr. Goodell detected two stones in the bladder, and removed them. At once all the symptoms of fistulous connection between the bladder and the bowels disappeared, and the patient got well. This rapid recovery led him to think that there had not existed any fecal fistulæ, but that the vesical tenesmus was so great as to cause a rectal tenesmus, which was masked by the former, and that the seeds and wind were voided per rectum unconsciously by the woman when attempting to empty the bladder. But he had been led to change his views by the following case which he had seen with Dr. Wm. Corson, and which Dr. Ellwood Corson was kind enough to report for him. Misled by the first case, Dr. Goodell was not at first disposed to admit the existence of a fecal fistula, but from the subsequent history of the case there can be no doubt of it. In this case he believed that a pelvic abscess had burst into the bladder and also into the rectum or small intestines, which had established the communication between the two viscera. Like the first case, as soon as the calculus was removed the fistulous tract closed and the patient got well.

Mrs. R., American, aged fifty years, the mother of five children. For three or four years prior to November, 1881, she was troubled occasionally by the passage of small calculi, but her health was reasonably good, with the exception of backache and an almost constant pain in the right iliac region. She often expressed her belief that there was something growing in the right side. There was no tumefaction in that region, and her opinion was based on the pain and distress she felt. She never applied to her physician for relief of this suffering. She was also troubled with constipation. In November, 1881, she made a visit to the country, and took a long walk. On her return home she had a constant desire to urinate, and she then noticed, for the first time, that her urine had an unnatural color, and a very unpleasant odor. The quantity passed was not excessive. This condition continued for five or six days, when there occurred a sudden gush from the bladder of a very offensive mixture of pus and urine, accompanied by great pain and straining. Her pain and distress became so great, and was so augmented by being on her feet that she was compelled to remain in bed. After the free discharge occurred, the pain in the right iliac region ceased, and she has never had any return of it.

As she was troubled with constipation, she was directed to eat stewed prunes, and she soon noticed that the prune-skins came from the bladder, as did other articles of food, along with the urine. Every day she was troubled with the escape of gas through the urethra, and this gave her as much pain as the passage of solid matter. She says that she occasionally passed urine through the rectum. She became greatly emaciated, and was but partially relieved of her suffering by the constant use of morphia. Until Jan. 20, 1882, she was under the care of homœopathic physicians. On that date, Dr. Wm. Corson was called to the case. Feb. 10th, Dr. Goodell saw her, and diagnosticated stone in the bladder. Feb. 20th, she was etherized and the urethra dilated, and a digital examination proved the existence of a calculus, about three-quarters of an inch in diameter, attached to the fundus of the bladder. This was removed by Dr. Ellwood Corson. In attempting to dislodge the calculus, it crumbled on slight pressure with the extracting forceps, and proved to be a mass of fecal matter with a calcareous crust, but slightly thicker than an egg-shell. While she was under the influence of the anæsthetic, an attempt was made to wash out the bladder, but after injecting f℥xij of water, and finding that it escaped into the interior of the body, and did not remain in the bladder, the washing-out process was discontinued. After she regained partial consciousness, and made a strong straining effort, the injection came away through the urethra.

As there were some doubts expressed as to the possibility of there being an opening from the bowels to the bladder, she was induced to eat a few stewed figs, and the seeds were *seen* to come from the urethra; on another occasion f℥viij of carmine-colored water were injected into the rectum and were immediately drawn from the bladder by means of a catheter. After the removal of the calculus it was thought proper to keep the bladder washed out daily with warm injections, and to regulate the bowels with mild aperients, but after persisting in this course of treatment for four days it was abandoned, as it caused her great discomfort and did not improve her condition. Afterward she was allowed to eat such food as the system craved, care being taken to select such articles as would not leave an irritating residuum. She rapidly improved, and since April, 1882, has had no trouble with her bladder. If she eats acid fruits or drinks lemonade, she has some irritation in passing urine. That there was a fistulous opening from the bladder to the rectum, there can be no doubt; and when we take into consideration the fact of an abscess forming somewhere in the right iliac region and opening into the bladder, and that the food passed from the bladder in a semi-digested state, and the absence of a fecal odor, there is a strong probability that there was also an opening from the small intestines into the bladder."

Dr. J. C. Morris had seen two cases of pelvic abscess bursting into the bladder. One case was in the person of a night-nurse at the Episcopal Hospital. A tumor in the lower part of the abdomen first attracted attention. The uterus was drawn up out of reach of the finger when making a vaginal examination; an inflammatory mass could be felt between the uterus and bladder; every half-hour a mixture of urine and pus was voided *per urethram*. If a catheter was passed into the bladder and turned to the right, urine escaped through it; but if it was passed to the left, nearly pure pus passed through it. Examination with the sound showed a large fibroid in the anterior wall of the uterus. This tumor having undergone purulent degeneration, and a fistulous opening being established in the bladder, the pus escaped through the bladder. A galvanic stem pessary, five and a half inches long, was introduced into the uterus, and was finally successful in effecting its reduction to the normal size. This woman died of fibroid phthisis, and at the post-mortem examination, the uterus was found but slightly enlarged, and the fistula into the bladder was not seen, but a communication from the small intestine into the bladder was discovered.

Dr. Wm. H. Parish had seen one case of fistulous communication between the bladder, vagina, and small intestine, resulting from an attempted abortion and consequent cellulitis. After long-continued pelvic symptoms, food commenced to pass through the bladder and the anterior and upper portion of the vagina. Water injected into the vagina passed into the bladder, but a sound could not be made to follow it. The food which passed through the fistula was incompletely digested.

Dr. Elliott Richardson read a

Report on Results of Post-Mortem Examination of the Body of Lina Earl.

This woman was operated upon September 22, 1880, for removal of a living child from the uterus by Cæsarean section, as modified by Porro and Müller. A report of the case was published in the American Journal of the Medical Sciences, Jan. 1881. The immediate results of the operation were in every way favorable.

The child was living and the mother made a speedy recovery.

She died in New York City on February 24, 1883, two years and five months after the operation. She had been for two years previous to her death at times an invalid, and was under my care occasionally for the treatment of attacks of acute rheumatism, anæmia, etc., to which her life of hardship and exposure as an exhibiting curiosity rendered her peculiarly liable. The more recent symptoms which appeared during the last illness I did not witness, but learned were attributable to defective action of the kidneys.

At the post-mortem examination, made about 9 P.M. on February 24th, ten hours after death, there were present Drs. Satterthwaite and Hegeman, of New York, and myself.

Inspection of the body showed the long bones of the extremities to be deformed as in rachitis; deformities which had not been so apparent during life. General anasarca was present. On the surface of the abdomen a cicatrix was observed extending from a point about one and one-half inch above the umbilicus to within about three-quarters of an inch of the symphysis pubis. This cicatrix was the remains of the abdominal incision made at the time of the operation for her delivery, and occupied the linea alba directly in the median line, except that at the umbilicus it was deflected to the left. Nearly the whole of that portion of the cicatrix extending between the symphysis pubis and the umbilicus was the site of a large hernia, which, however, did not extend into the latter. This hernia I had seen during the patient's life. It began to appear about six months after the operation, and received no treatment whatever until by its size it became inconvenient, then a bandage or truss was applied, and this she wore constantly until her death. The production and enlargement of the hernia had been greatly favored by the woman's course of life as an exhibitor of herself and child, for the latter she lifted up and held in her arms many times a day in order to display it to her visitors, even after it had become much too heavy for her to carry.

The body was opened by a long incision from the top of the sternum to the symphysis pubis. This incision was deflected to one side opposite the cicatrix of the old abdominal wound, in order that the relations of this to the abdominal contents might be more closely observed. The body, as before stated, was anasarcous throughout; some clear serous fluid was found in the peritoneal cavity, and a good deal in the cavities of the pluræ and the pericardial sac.

Dr. Richardson very much regretted that he had no data of microscopic appearance of any internal organ or tissue to give. Only the gross lesions which could be detected by the unaided eye in a hasty examination can be given. The heart was not opened, but the left ventricle appeared abnormally large. The lungs were œdematous, and pneumonia of the right side was observed. The spleen was enlarged. The liver presented an appearance of fibrous or "hob-nail" degeneration. The kidneys showed unmistakably the existence of Bright's disease. The abdominal and pelvic cavities gave no evidence of any peritoneal or cellular disease. The hernia was found to be covered by peritoneum and skin; the remaining structures having parted to admit the protrusion of the intestines and peritoneal covering. No adhesions between the cicatrix and subjacent structures could be detected except at the lower angle of the wound. It was at this point that the stump of the uterus had been fixed, in a manner similar to the disposal of the pedicle in ovariotomy. A fibrous band was found extending from a depression in the abdominal wall, at this point, to a body consisting of the remains of the uterus.

Dr. Satterthwaite, who examined these specimens, writes that this body, which occupied nearly the normal position of the cervix uteri, except that it was displaced somewhat anteriorly, presented the following characteristics: "The extreme length of the stump was 4.75 cm. (1.87 inch); vertical thickness 2.5 cm. (1 in.); its breadth 1.5 cm. (½ in.). On attempting to pass a uterine probe into the os externum, it was found to enter with difficulty, though the cervical canal was capable of admitting a No. 10 (English) sound. The mucous membrane was coated with a deposit of white, thick, gelatinous material, and was intact for a distance of 3.5 cm. (1¼ in.). No naked-eye evidences of cicatricial tissue were made out at the amputated extremity of the neck."

Examination of the pelvis *in situ* was of much interest to me. Measurement of the superior strait gave for the

Conjugate diameter,	.	2 inches exactly.
Transverse "	.	4¼ "
Oblique "	.	4⅜ "

The pelvis was a rachitic one, although the pavilion did not present the wide-spreading alæ or the diverging anterior-superior spinous processes of the ilia, which are the usual deformities of rachitis in this part of the pelvis. The true pelvis, however, presented highly characteristic deformities. The sacrum was at its upper part dislocated, and pressed downward and forward into the pelvic cavity, while the lower extremity, being held by ligamentous bands to the ischia and pelvic bones, caused a sharp bending forward of the last three vertebræ of the sacrum. This deformity implied abnormal softness and pliability of the bone at a time when the individual was of sufficient age to either stand or sit erect, so that it alone is conclusive evidence of rachitis having existed. The normal curvature of the pubic bones was nearly lost, so that they receded from the symphysis in nearly straight lines backward and outward to join the ischia and ilia, the two pubic bones when viewed from above forming an abnormal angle at the symphysis. The shape of the superior strait was therefore obtusely cordate, deeply indented at its base by the promontory of the sacrum projecting far into it. I was much surprised at the evidences of rachitis, which became more and more conclusive as the examination proceeded. Since the history of the patient formally given me was that of excellent health from birth to the time of the operation, in 1880, and we were told by the woman, and those who had known her best in early life, that she was in her figure an almost exact counterpart of her father, these facts—as I supposed them to be—led me to believe that her shape was due to arrested growth, and not to rachitis.

It will be of interest to know that the child of this woman is now living, that he is well developed, and presents no deformity nor any symptom of rachitis. He is of fair size for his age.

In closing, Dr. Richardson drew the following conclusions from the examination:

1. That the deformity of pelvis and extremities was due to rachitis.

2. That the operation had nothing to do with the patient's death.

3. That the operation caused the patient no inconvenience except from the hernia, which would either not have become developed, or at most would have been small, had it not been for the exposure of the woman to unusual strain, and her total neglect to resort to any treatment until the hernia became large.

4. That success, in so far as the woman was concerned, would have been possible, and even probable, with diameters so large if embryotomy had been re-

sorted to in this case, but the operation would still have been dangerous and the child would necessarily have perished.

Dr. R. P. Harris remarked that of five Porro operations in this country, four have been fatal. This is the first successful operation in which a post-mortem examination has been obtained after entire recovery.

Dr. Richardson, in reply to Dr. A. H. Smith, stated that no trace of a fistulous opening between the stump of the uterus and the abdominal wall existed at the time of death.

Dr. B. F. Baer read the history of a case of

SUPPURATING CYST OF THE BROAD LIGAMENT, WHICH HAD PERFORATED THE BLADDER,

and exhibited the specimens removed by laparotomy. The characteristic points were chills, exhaustion, anorexia, tenderness throughout the lower abdomen, and a small, painful tumor in the left iliac region, with great irritability of the bladder. Pulse 120, temperature 100° to 102°. The tumor extended down between the bladder and uterus, and the latter was retroverted. Douglas' cul-de-sac was occupied by a thin-walled fluctuating cyst, about the size of a large orange. The uterus could be moved slightly from side to side; the anterior tumor rested on the bladder and was adherent to it. The history showed a slowly growing cyst with purulent contents, commencing about three years before, when the first chills and a mild septicæmic fever had occurred. Gradual emaciation had been going on since that time. Tympanitic resonance of the tumor gave evidence of decomposition with evolution of gas. When the catheter was passed before operating, several ounces of very fetid pus flowed through it, showing a spontaneous rupture of the cyst into the bladder. The cyst was found adherent to the abdominal wall and to the bladder, but not to the intestines or uterus. The cyst was aspirated and removed by laparotomy. The pedicle, consisting of broad ligament and Fallopian tube, to which the left ovary was adherent, was transfixed and ligated. The cyst in Douglas' pouch arose from the opposite broad ligament; it had formed no adhesions and was removed without evacuation of its contents. The ovary and Fallopian tube were healthy and were not removed. The aperture in the bladder through which the contents of the cyst had escaped, was valvular, and was closed by the compression furnished by the external dressings. The patient died from exhaustion soon after the close of the operation.

Dr. Baer cited cases from W. L. Atlee, Peaslee, Keith, George F. French, and Goodell, to prove the correctness of the principles upon which he operated.

Dr. W. H. Parish thought Dr. Baer's rules safe and sound; he had removed a suppurating cyst with anterior adhesions. An experienced operator, who was present, recommended delay, but feeling sure of the correctness of his own principles, he removed the cyst and the patient recovered. In another case, in which a fistulous opening discharging pus existed, suppurative peritonitis was diagnosticated, but after death from septicæmia, a post-mortem examination revealed a suppurating cyst of the ovary.

NEW INVENTIONS.

A SIMPLIFIED EVACUATOR FOR LITHOLAPAXY.

Dr. Henry J. Bigelow has modified the evacuating instruments used in litholapaxy, with the view of securing a form which will hold securely the fragments after aspiration. This has been the chief difficulty which had yet to be overcome in all evacuators heretofore made. Dr. Bigelow finds that the simplest way of obviating this difficulty is to collect the fragments in a bulb, and prevent their escape. For this purpose he uses a straight cylinder with perforated walls, which is nothing more than a prolongation of the catheter into the bulb. The water which brings the fragments from the bladder is strained on its return. He says: "To the open end of this perforated cylinder a valve might be attached, either a ball-valve moving loosely, which is less liable to obstruction than a valve with a hinge, or still better at the same point, half an inch of collar tube which opens, allowing the fragments to pass up through it, and collapses with the reversed current, cutting off their retreat; the water as it returns passing back through the perforated walls. In operating with this instrument I have found it to work perfectly, but a valve is not necessary, and the apparatus is more simple without it."

Fig. 1.

Dr. Bigelow's evacuator, with elastic bulb, glass receiver, and stop-cocks. Below is a metal brace, between the collar of the glass receiver and that of the catheter, to steady the latter. Within the bulb, and open at the end, is a tube-strainer to prevent the return of débris.

The instrument is shown in Fig. 1. The catheter enters a spherical bulb obliquely upward, is prolonged to the centre of the cavity by the perforated tube referred to, which is open at the end. The catheter, tube, and elastic bulb are in a straight line. By this arrangement the current is not *deflected*, and in this manner the force is not diminished. During the operation the current, with the débris, passes from the bladder straight through the tube into the widest part of the bulb, and the fragments fall into the receiver. When the bulb is compressed the water returns almost entirely through the perforations in the tube, their area being collectively larger than the opening at the end of it, and they being also nearer the point of exit of the water from the bulb. By this means *the return of the fragments is practically prevented.* In case of obstructions to the tube-strainer by mucus, coagula, or other material, it can be removed and cleansed in a few moments. Dr. Bigelow thinks that even when the tube continues to work well, it is better to pass a brush over it if any mucus adheres to it. The perforated tube is a valuable addition, and meets the requirements. It is best not to fasten

the tube permanently into the bulb, the cavity of which should always be easily accessible.

Dr. Bigelow claims other advantages for this arrangement: 1. When the trap is within the bulb, the instrument is more compact, shorter, and more easily managed, and the bulb, being in a straight line with the catheter, forms a handle which enables the operator to direct the catheter more easily. 2. The glass receiver, being attached immediately below the bulb, is more easily seen. 3. A brace unites the metal collar of the catheter with that of the glass receiver, and so steadies it that the catheter does not feel the movement of the bulb. Patients often complain of this oscillation when the ordinary instruments are employed. This result is further attained by the conical projection of the bulb at the point where the catheter is attached. 4. An elastic hose (Fig. 2), easily attached to the top of the

FIG. 2.

Apparatus belonging to Bigelow's evacuator, but not essential to it, viz., a tunnel and a hose, both of which fit on to the top of the bulb, and an extra stop-cock for the evacuating catheter.

bulb, facilitates the operation. With this, any air or discolored water can be driven out and clean water introduced, by a single compression of the bulb, with no delay and without taking off the catheter.

By this arrangement, in short, we can regulate the amount of water in the bladder at any time—a very important point. This should be regulated, at first, according to the capacity of the bladder; then it may be necessary to withdraw the water quickly, in case of retching, to allow for the muscular strain, or to relieve the violent expulsive efforts of the bladder, which may become very tense. One end of the hose being attached to the bulb, the other can remain in a vessel placed between the patient's knees, or in any other convenient place. The hose, however, is not essential. A funnel is furnished with the instrument, for those who prefer it, Fig. 2; also a second stop-cock, Fig. 2, which, if attached to the head of the catheter, is useful in keeping the bed-clothes dry when the bulb is removed. This improved instrument is made by Codman & Shurtleff, of Boston.

CORRESPONDENCE.

PREHISTORIC TREPHINING.

To the Editor of THE MEDICAL NEWS.

SIR: The editorial in your number for March 24th, entitled "Prehistoric Trephining," caused me to hunt up a curious passage in *The Anatomy of Melancholy*, and having found it, I have made a note of it. Here it is:

"Cauteries and hot iron are to be used in the suture of a crown, and the seared or ulcerated place suffered to run a good while. 'Tis not amiss to bore the skull with an instrument to let out the fuliginous vapours." Sallus Salvianus, *de re medic, lib. 2, cap. 1.* "because this humour hardly yields to other physics, would have the leg cauterized, or the left leg, below the knee, and the head bored in two or three places," for that it much avails to the exhalation of the vapours: "I saw (saith he) a melancholy man at Rome, that by no remedies could be healed, but when by chance he was wounded in the head, and the skull broken he was excellently cured." "Another, to the admiration of the beholders, breaking his head from a fall from on high, was instantly recovered of his dotage." Gordonius, *cap. 13, part 2*, would have these cauteries tried last, when no other physic will serve. "The head to be shaved and bored to let out fumes, which without doubt will do much good. I saw a melancholy man wounded in the head with a sword, his brain-pan broken; so long as the wound was open he was well, but when the wound was healed, his dotage returned again." But Alexander Messaria, a professor in Padua, *lib. 1, pract. Med., cap. 21, de melanchol.* will allow no cauteries at all, 'tis too stiff a humour and too thick, as he holds, to be so evaporated. Guianerius, c. 8, *Tract* 15, cured a nobleman in Savoy, by boring alone, "leaving the hole open a month together," by means of which, after two years' melancholy and madness, he was delivered. All approve of this remedy in the suture of the crown; but Arculanus would have the cautery to be made with gold. In many other parts, these cauteries are prescribed for melancholy men, as in the thighs (Mercurialis consil., 86), arms, legs. *Idem consil.* 6, and 19, and 25. Montanus 86. Rodericus à Fonseca *tom.* 2, *consult.* 84, *pro hypochond. coxa dextrâ*, etc., but most in the head, "if other physic do no good."

Burton's immortal work was first printed in 1621.

Yours truly,

WALTER F. ATLEE.

PHILADELPHIA, April 9, 1883.

OBITUARY.

JOSEPH K. BARNES, M.D., LATE SURGEON-GENERAL, U. S. ARMY.

BRIGADIER-GENERAL JOSEPH K. BARNES (retired), late Surgeon-General, United States Army, died at his residence in Washington, D. C., on the morning of April 5, 1883. He was born in Philadelphia, July 21, 1817; studied medicine in the office of Dr. Thomas Harris, and graduated from the Medical Department of the University of Pennsylvania in 1838. After graduating, he served for one year as resident physician in Blockley Hospital, and one year as physician to the poor in the northwestern district of Philadelphia. He then entered the army as assistant surgeon, his commission being dated June 15, 1840. After four months' service at West Point, he was sent to Florida, where he was on duty with Harney's expedition during the Seminole War. He left Florida in 1842, and was stationed at Fort Jessup, Louisiana, until 1846, when he went to Corpus Christi. During the Mexican War he was chief medical officer of the Cavalry Brigade, and took part in every action on both General Taylor's and General Scott's line, except that at Buena Vista. After the close of the Mexican War, he was in charge of the general hospital at Baton Rouge, La., and then served in Texas, and as Medical Director of the Department of Oregon. From 1854 to 1857 he was at

West Point, after which he was transferred to the Pacific Coast. He was commissioned as surgeon, August 29, 1856.

At the outbreak of the war he was summoned to Washington. He was appointed a medical inspector, with the rank of Lieutenant-Colonel, Feb. 9, 1863, and, on August 10th of the same year, he was promoted over several other inspectors to be the Medical Inspector-General, with the rank of Colonel. On the dismissal of Surgeon-General Hammond, Dr. Barnes was selected to succeed him, and became Surgeon-General, with the rank of Brigadier-General, August 22, 1864. He was breveted Major-General in 1865, and was retired, June 30, 1882, under the recent law prescribing retirement at the age of sixty-four. The cause of his death was Bright's disease, the first symptoms of which were observed about one year ago.

Early in the war, Dr. Barnes attracted the attention of Mr. Stanton, the Secretary of War, who became his steadfast friend; and it was largely due to this friendship, and the consequent support of the Secretary, that General Barnes was able to accomplish so much towards placing the medical department of the army on a proper standing as regards the control of hospitals and hospital-transports. The efforts of local commanders to obtain control of hospital-boats, in order that they might be used occasionally for other purposes, were vigorously contested by General Barnes, and, in consequence of his energetic appeal to the War Department, an order was finally issued, Feb. 8, 1865, directing that "hospital-transports and hospital-boats, after being properly assigned as such, will be exclusively under the control of the medical department, and will not be diverted from their special purposes by orders of local or department commanders, or of officers of other staff departments."

After the assassination of President Lincoln, there was a general feeling that the theatre in which the event occurred should no longer be used as a theatre, but should become the property of the United States. The collections of medical and surgical specimens made during the war had at that time no sufficient room for safekeeping and exhibition, and General Barnes proposed that the theatre should be transferred to the medical department of the army, and used to store the medical and hospital records of the war, and to serve also as a museum. His request was granted; and the Army Medical Museum, the Library connected with it, and the work done in both are well known to medical men all over the world as the result.

As a practical physician and surgeon, General Barnes had a high reputation in Washington, and his name is familiar to the country as one of the consulting surgeons in the case of President Garfield.

In the announcement of his death in General Orders, the Adjutant General says: "He was eminent, skilful, and successful in his profession as surgeon and physician, and distinguished for great administrative ability as the head of the medical department. He inaugurated the *Medical History of the War;* he founded the Medical Museum, and he brought the Medical Department to the highest state of efficiency. . . . At the time of the assassination of President Lincoln and the attempted assassination of Secretary Seward, he attended at the death-bed of the one and ministered with untiring energy and skill to the successful restoration of the other. So during the long illness of President Garfield, he was one of the distinguished surgeons of the land, who for days and nights served in the chamber of the dying President. During these long protracted hours of anxiety and care, his own health gave way, and from that moment to the time of his death he was an invalid. His career was one of honor to himself and of great service to his country."

The medical profession of the United States will emphatically endorse this just and discriminating eulogy.

Surgeon-General Barnes was buried with military honors at Oak Hill Cemetery, Georgetown, on Saturday last.

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

The Code of Ethics.—The Council of the Central Organization of the New York State Medical Association has just issued the following circular, with a view of securing, through branch associations in every county in the State, united and earnest efforts to restore the Medical Society of the State of New York, and its auxiliary county societies, to their former position of affiliation with sister State medical societies, and also with the American Medical Association:

"*To the Members of the regular*
"*Medical Profession in the State of New York.*

"Gentlemen: Representing a large number of physicians associated to uphold the National Code of Medical Ethics, we beg leave to ask you to consider the importance of the object.

"The so-called New Code recently adopted by the Medical Society of the State of New York, sanctions fellowship, by means of consultations, with all practitioners who are 'legally authorized to practise medicine.' This sanction extends to practitioners who have adopted designations intended to distinguish them as belonging to sects apart from, and hostile to, the regular medical profession, and who are organized in order to lessen public respect for this profession and for its members. Will you not seriously consider the question whether under these circumstances affiliation by any act with sectarian or irregular practitioners is consistent with a due regard for the honor of the profession, or with a proper sense of self-respect?

"The New Code has dissevered all connection by representation, of the Medical Society of the State of New York and its auxiliary County Medical Societies with the American Medical Association, and also with the State Medical Societies of the several States of the Union. At the last meeting of the American Medical Association (1882) the Judicial Council decided as follows: 'Having carefully examined the Code of Ethics adopted by the New York State Medical Society, at its annual meeting in February, 1882 (as furnished by the Secretary of said Society), the Judicial Council find in the said Code provisions essentially different from, and in conflict with, the Code of Ethics of this Association; and therefore, in accordance with the provisions of the ninth by-law of the American Medical Association, they unanimously decide that said New York State Medical Society is not entitled to representation by delegates in this Association.' The following is the by-law referred to in the foregoing decision: 'No State or local Medical Society, or other organized institution shall be entitled to representation in this Association that has not adopted the Code of Ethics, or that has intentionally violated, or disregarded, any article or clause of the same.'

"We submit to your consideration that the substitution of the New Code for that adopted by the American Medical Association has inflicted upon the medical profession of this State a great injury and disgrace.

"It is believed that the recent action of the New York State Medical Society in relation to the Code of Ethics is not sustained by the sentiment and judgment of the great majority of the medical profession in the State. But even granting that they who are opposed

to this action are in the minority, it must be admitted that the number is very large. The effect of the action of the State Society, if persisted in, will be a division of the profession of the State into two parties. In view of the evils which cannot but follow such a division, and the many advantages of harmony, we appeal most earnestly to those who have been led to approve of the substitution of the New Code for that of the National, to reconsider the matter, and we solicit the active coöperation of all who are in favor of the National Code, in concerted efforts to effect, as speedily as possible, a reversal of the action of the Medical Society of the State of New York at the annual meetings in 1882 and 1883.

"Communications from societies and individuals who are in sympathy with associations for upholding the National Code of Ethics, and resisting any modifications of that Code which does not emanate from the American Medical Association, may be addressed to JOHN H. HINTON, M.D., No. 41 West 32d Street, New York City.

"Abram DuBois, M.D., J. W. S. Gouley, M.D., Wm. T. Lusk, M.D., Austin Flint, M.D., John H. Hinton, M.D., Samuel S. Purple, M.D., Austin Flint, Jr., M.D., Samuel T. Hubbard, M.D., T. Gaillard Thomas, M.D."

The advocates of the New Code are also at work. Under date of March 30th, they issued the following circular:

"DEAR DOCTOR: You are earnestly requested to attend a meeting to be held at the residence of Dr. Abraham Jacobi, 110 West 34th Street, on Friday evening, April 6th, at 8.30 o'clock, for the purpose of considering the present status of the ethical question.

"Yours respectfully,

"ALFRED C. POST,	S. O. VANDERPOEL,
"C. R. AGNEW,	ROBERT F. WEIR,
"FORDYCE BARKER,	A. JACOBI,
"W. H. DRAPER,	A. E. M. PURDY,
"F. N. OTIS,	THOS. ADDIS EMMET,
"H. B. SANDS,	ALFRED L. LOOMIS."

In response to this invitation, more than fifty physicians, representing various sections of the State, were present.

Dr. Jacobi said, in calling the meeting to order, that the opposition of those who favored the Old Code had been persistent, and was at the same time carried on secretly. It had gained some strength, and it was necessary that the public and physicians who are not informed on the subject shall learn what has been done.

Dr. Post was elected Chairman, and Dr. F. R. Sturgis, Secretary. In the informal speeches that followed, it was the unanimous sentiment that the New Code should be sustained in any event. Some of the physicians were in favor of making a determined fight at once. Others wanted the whole matter ventilated thoroughly but quietly, and in a spirit of conciliation, in order to avoid the split which they said the Old Code men wished to make.

It was said that the Old Code had been obsolete for years, when the New Code was adopted it was simply a question of New Code or no Code. The New Code, by leaving it in the option of regular physicians to consult with homœopaths, merely broke down the barriers that separated both schools.

The Chair appointed a committee of fifteen to consider the matter, and to report a series of resolutions thereon. Those resolutions will be distributed throughout the State for the information of the profession. The report will be made at a meeting to be called shortly. The committee are, Drs. Loomis, Sands, Weir, Post, Sturgis, Little, Barker, and Roosa, of New York; Ely, of Rochester; Hutchins, of Syracuse; Potter, of Buffalo; and Pilcher and Prout, of Brooklyn. This committee will report a plan of action. Among the physicians present from out of town, were Drs. Bailey and Vanderpoel, of Albany; Dr. Hutchinson, of Utica; Dr. Adams, of Carmel, Putnam Co.; Dr. Potter, of Buffalo; and Drs. Ely and Stoddard, of Rochester.

A professional writer describes the existing state of medical politics in New York State as follows:

The sad and lamentable situation in which members of the profession of almost the entire State are placed at the present moment—disfranchised and shut out from affiliation with their brethren of the National and State Medical Societies of the Union, through injudicious and reckless legislation—is one which cannot fail to enlist the sympathy and the earnest efforts of the good and true men of our country to overturn. The efforts of certain aspiring, but indiscreet specialists, which have been realized to effect unwise legislation in the profession, and to permit affiliation with all "legally qualified practitioners," many of whom are of undoubted quackish proclivities, and who have no claims to honorable recognition as physicians but that which comes through the ill-advised, levelling, and specious "Registration Act," have already received, and will continue to receive, the just censure and condemnation of all who hold professional obligations sacred, and who believe that blighted honor is the legitimate fruit of broken pledges.

The *New York Tribune*, in commenting on this state of affairs, says: "Nothing could better illustrate the earnestness of the physicians in the present contest over the ethical code of the American Medical Association than the thoroughness of the work of organization now going on. The State Medical Society cannot consider the question again until next February; yet it is probable that long before that time nearly every regular practitioner in the State will have been asked to commit himself by signature for or against the re-enactment of the Old Code. When next a pitched battle is called, therefore, the contestants will go into the field each side with a perfect knowledge of not only the number, but also of the personality of the other. This city has already been very thoroughly canvassed, and a large majority of the eight hundred or nine hundred members of the County Society have formally arrayed themselves under their colors. The canvass is now to be extended all over the State, and rival literary bureaus have begun to prepare the mind of the rural practitioner for the irrepressible conflict.

"In the medical reviews the controversy has been going on for several weeks. The two largest medical papers in this city are pronounced in their opposition to the Old Code, with this difference: While *The New York Medical Journal* believes the New Code to be a step in the right direction, its preference is for no code at all; *The Medical Record* is 'flat-footed' in favor of the New Code."

WASHINGTON.

(*From our Special Correspondent.*)

THE NATIONAL MEDICAL LIBRARY AND THE LIBRARY OF CONGRESS.—An article has recently appeared in one of the weekly papers of Washington, *The Sunday Herald*, which deserves more than a passing notice. It comments upon the great increase in value of the libraries of Washington, of the increased demand by readers for works printed in foreign languages, and stigmatizes as a fraud the National Medical Library, because its Librarian, Dr. Billings, has found it has grown to such dimensions, and to be of such importance, that he does not care to have it lost in the mass of books which have long since grown out of Mr. Spofford's control, as the Librarian of Congress. Not that

Mr. Spofford is responsible for this loss of the control—for it probably causes him more positive chagrin than any one else concerned in the matter—and not but that he is as capable a man as can be found for conducting a library many times its present size, but the U. S. Congress *will not* help him out of his dilemma.

This newspaper writer makes two statements which show that his information is obtained from unreliable sources. He says: "But the general public has no library." The rooms which contain the books of the library of Congress are now so heaped up with volumes that the librarian and his assistants have scarcely room to turn around in, and every now and again there comes from the upper stories an unexpected book-slide, which imperils literature and brains alike, both being top-heavy. Notwithstanding this condition of things, there are always tables kept vacant and convenient for the express use of the general public; and a visitor can always see a fair proportion of boys with Beadle's dime novels, or their progenitors, our colored brethren, with big books containing dictionary words, and cranks taking notes from a mass of odds and ends, seated at these tables and using them as freely as they please. It is astonishing sometimes to see how much trouble is taken to furnish an applicant—and he may be of the unwashed general public—with the literature he asks for. It is very probable that Mr. Spofford has still in the library a few anatomical works, with plates, for pruriency of whatever age, to study the organs of generation, etc., from, and it is certain that boys cannot pursue such studies advantageously in the National Medical Library.

He says, further, that the National Medical Library is held for the exclusive benefit of a few people in the Surgeon-General's Office and their friends. Very true, but their friends seem to embrace the whole of the medical profession, judging from the statement made in Congress on February 21st, where it was shown that during the past year, books had been loaned to Boston, New York, Philadelphia, Baltimore, Chicago, Cincinnati, St. Louis, and other cities; and other people had better let the great majority of these books alone. "That the library has published nothing, aside from the *Medical History of the Rebellion*, which was a mere, complication of other peoples' writings by Dr. Woodward and his associates." This, in the face and eyes of the three volumes now published of the *Index Catalogue*, is truly a complication all around. What does the writer expect the library to publish? He meant of course, compilation, but he makes a statement which might have come from a high private in the ranks, or perhaps a first-class clerk *c'est toute la même chose*, as these are the men who are the most apt to complain of the work done by them, which they assume their superiors in rank simply sit down and enjoy the fruits of; for the higher the position is, which a man holds in such work, the better able is he to appreciate the responsibilities and qualities of the one above him.

But, although we may treat this matter in a spirit of raillery, still it has its serious aspect, and the profession may yet be called upon to express an opinion as to what shall be the ultimate destination of the present National Medical Library. Mr. Spofford favors a vast general library, which shall absorb this as well as all other libraries now under the control of the United States Government in Washington. His scheme is to allow the various departments all the books they may require for working purposes, *i. e.*, their tools; but that all books beyond these shall be put into the general library, and thus avoid the expense of duplicating costly books.

The statement made by the *Herald* writer, that there was an understanding between the two librarians that, when the *Medical and Surgical History of the War of the Rebellion* was completed, the books now constituting the National Medical Library should be merged into the Library of Congress, requires explanation. When the present librarian of the Surgeon-General's Office took charge of the books, there were between two and three thousand volumes on hand; these soon grew to the number of thirty thousand volumes; and it was then, with the *Index Catalogue* as a determined project in the mind of the librarian, and as a stimulus for absorbing all available material, that the medical matter in the Library of Congress was asked for, and Mr. Spofford's coöperation was requested. The argument was used that there was not, even at that time, proper accommodation for these books; that they could be better utilized by the Surgeon-General's Library; and that it would be time enough, when the scheme for a universal library had taken proper shape and form, to consider the propriety of returning them. Under this arrangement some fifty volumes of medical periodicals, and, perhaps, some two thousand medical pamphlets, largely inaugural theses, and in great part representing a deposit from the Smithsonian Institution, were withdrawn from the Library of Congress. These books, we understand, are held at the disposition of the Librarian of Congress. No copyrights, of which two of every book so published are deposited, were allowed to be so used, but the Smithsonian accessions, which are varied and somewhat extensive, were diverted, so far as medicine was concerned, into this new channel.

Mr. Spofford is positive that there was a distinct understanding that all the books as they accumulated should, when the proper time came, be again a part of the Library of Congress; but these two librarians cannot arrange such matters amongst themselves with a view alone to their mutual satisfaction. It is for the profession to indicate how these books shall best be preserved, and how the growth of the library shall best be fostered for the benefit of the medical science.

The profession must necessarily look with jealousy and critical scrutiny upon any scheme that will take this library out of the hands of its present management. In the first place, they must recognize that the phenomenal growth of the library is really due to the peculiar fitness and untiring energy of its chief, Dr. Billlings, and in the judgment which he has shown in the selection of his assistants. His personal interest also in general matters which affect the profession has given him a much wider scope and larger field to draw from than would ordinarily be at the disposition of one who was simply a librarian. They must further recognize that medical men should always have charge of the purchase, selection, and arrangement of medical literature; and to make it satisfactory to those who are to profit by it, any other arrangement would require a staff of medical men who, if their abilities are to be in any way commensurate with the duties they would be called upon to perform, would require higher salaries than those of the general assistants to librarians. Further, who shall decide what books are necessary to the work of a department, and what books are not? This involves nice questions that might cause much discussion.

Since the development of the National Museum, the Smithsonian Institution draws constantly and extensively upon its deposit in the Library of Congress for the works which it needs to retain as its working library; and the Medical Museum in the same way requires a large amount of books of reference to be constantly at hand. If it was necessary in the first signs of vigorous growth of the Surgeon-General's Office and the Museum, for Dr. Billings to induce the Librarian of Congress to allow the use of these books, and to aid in obtaining further appropriations for in-

creasing their number, it certainly now, in the full fruition, becomes even yet more and more important that the collection should be kept up and added to. The National Medical Library is freely open for consultation, and if it is not more accessible, and is in daily peril of destruction, it is the fault of the United States Government, which fails to provide it with a suitable building.

In the last days of the session of the last Congress, too late for action, a report was presented from the Committee on Public Buildings and Grounds, recommending the purchase of a site, and the erection of a fire-proof building thereon, to contain the records, library, and museum of the Surgeon-General's office. The report set forth the insecurity of the present building used for the purpose—its walls, far out of plumb, in danger of falling, its roof not fire-proof, and its surroundings of frame shanties. It recommended as a site the neighborhood of the National Museum, and a building to cover an area of about 21,000 square feet, *i. e.*, about 1,350,000 cubic feet, to cost not more than $200,000. This allows for the diminution in time of the clerical force of the record and pension divisions, and consequently room for the laboratory and necessary scientific work of the museum. May it be introduced early and successfully at the next session.

CANADA.

(*From our Special Correspondent.*)

MEDICAL SCHOOLS.—The Annual Convocation of McGill University, for conferring degrees in medicine, was held on the 31st inst., when thirty successful candidates were presented.

At the Montreal School of Medicine (French) thirty-three students have passed the final examination, and will receive the degree from Victoria College, with which the school is at present affiliated.

At the convocation of Bishop's College, held on the 5th, the degree of M.D. was conferred on three candidates.

The examinations of the Ontario Medical Council, for the license to practice in that province, began at Kingston and Toronto on the 3d.

LAVAL UNIVERSITY.—A recent Papal decree settles finally the question of the Montreal Branch of this College, and has created no little excitement among French-Canadian members of the profession, as the Faculté de l'Ecole de Medicine is required not only to desist from further opposition, but to sever its connection with Victoria College, Coburg, a Protestant institution, from which the students obtained degress. What its action will be remains to be seen.

MEDICAL ASSOCIATION OF GEORGIA.—The thirty-fourth annual session of the Medical Association of Georgia will be held at Athens on the 18th inst.

THE UNIVERSITY OF LOUISVILLE held its forty-sixth annual commencement on February 27th. Diplomas were given to sixty-eight candidates. Dr. Theophilus Parvin delivered the valedictory address on behalf of the faculty.

THE ANNUAL COMMENCEMENT OF THE MISSOURI MEDICAL COLLEGE was held in St. Louis on the afternoon of March 6th. The valedictory address was delivered by Dr. John Snyder.

AT THE ANNUAL COMMENCEMENT OF THE ST. LOUIS MEDICAL COLLEGE forty candidates received the degree of Doctor in Medicine. A portrait and marble bust of the late Dr. John T. Hodgen, Professor of Anatomy in the St. Louis Medical College, were presented by Dr. E. H. Gregory. Dr. Boisliniere delivered the valedictory address.

THE ANNUAL COMMENCEMENT OF THE MEDICAL DEPARTMENT OF VANDERBILT UNIVERSITY was held on the evening of February 26th. The degree of Doctor in Medicine was conferred on one hundred candidates. Dr. J. W. Dodd delivered the faculty address to the graduates.

NEW ORLEANS, LA., AND THE SANITARY COUNCIL.—New Orleans will be largely represented at the meeting of the Sanitary Council of the Mississippi Valley, at Jackson, Miss. Delegates have been appointed by the City Council, the Auxiliary Sanitary Association, the Medical and Surgical Association, the Orleans Parish Medical Society, the Chamber of Commerce, the Brokers' Exchange, the Cotton Exchange, the Stock Exchange, the Mechanics', Dealers', and Lumbermens' Exchange, and the Illinois Central Railroad Company.

The representatives of these bodies held a meeting, March 31, which was attended by many gentlemen who were not delegates, among them some members of the Louisiana State Board of Health. The object of the meeting was to discuss the questions which would be brought up at the coming meeting of the Sanitary Council of the Valley, and to formulate some manner of harmonizing action. Enquiry was made of the members of the State Board present, whether that Board would be represented at the Council, and whether any assurance could be given that the Board would immediately report any actual cases of yellow fever, and give the benefit of the doubt in suspicious cases to the people of the neighboring States. In reply, it was stated that it was inexpedient for the Board to be represented at the meeting of the Council—that the relationship existing between the Board and many members of the Council is such that it would be unwise for the Board to have a delegation at Jackson.

It was understood that the two objects which would probably be discussed at the meeting of the Council, were the river and railroad inspections, and the epidemic fund of $100,000, appropriated by Congress and placed at the disposal of the President. Mr. Clark, of the Illinois Central Railroad, said that if every other resource failed, he would be willing to pay for the inspections himself.

BANQUET TO DR. HOLMES.—DR. OLIVER WENDELL HOLMES was entertained at a banquet at Delmonico's, on Thursday evening, by the medical profession of New York.

A MEDICAL "COLLEGE" SCOTCHED BUT NOT KILLED.—A judgment of the New York Supreme Court against Robert A. Gunn and others, originators of the "United States Medical College," has been received at the office of the Board of Health of New York. This institution, it is declared, never has been incorporated as a medical or surgical college, and does not possess the powers or franchises of one. The persons named in the judgment are therefore restrained from granting medical diplomas. The Bureau of Vital Statistics was warned to "reject and refer to the Honorable Board of Coroners all certificates of death signed by graduates of the above-mentioned college, as they have no legal standing as physicians."

In the mean time, a bill has been passed by the State Assembly and is now in the Senate, which is believed to be an attempt to resuscitate the United States Medical College of this city, and nullify the judgment obtained recently in the Supreme Court, declaring it to be not properly organized. The bill was never sent

to a committee in the Assembly, but by unanimous consent was read twice and ordered to a third reading. It was heard of by chance, and by hard work a hearing has been arranged for before the Senate Committee on Miscellaneous Corporations. The bill is entitled "An Act to Legalize and make Valid the Incorporation of Certain Scientific, Medical, and Literary Colleges and Universities," etc., and amend certain previous acts.

The amended act provides as follows:

"All scientific, medical, and literary colleges, universities, and all associations of five persons or more, a majority being citizens and residents of this State, which have filed their several certificates with the intention of organizing or incorporating under said acts a scientific, medical, or literary college or university, and which have reported to said Regents within the two years last past, are hereby declared to be and to have been legally incorporated, upon the filing of their said several certificates, for the purposes set forth therein, and with all the rights, powers, and authority incident to and possessed by corporations duly organized for such purposes; and all by-laws heretofore made by such colleges, universities, or associations, all elections held, and all degrees and diplomas conferred, and all the official acts and proceedings of the trustees named in such certificates, and of their successors, incident to said purposes since the filing of said certificates, are hereby ratified and confirmed, and all rights arising therefrom are hereby secured and perpetuated; and all such colleges and universities shall be subject to the same duties, liabilities and obligations, and to the same control and visitations of said Regents as colleges and universities chartered by said Regents."

Health in Michigan.—Reports to the State Board of Health for the week ending March 31, 1883, indicate that rheumatism, consumption, bronchitis, and dysentery increased, and that remittent fever and whooping-cough decreased in area of prevalence. Compared with the average for the month of March in the preceding six years, measles and influenza were more prevalent, and whooping-cough and remittent fever less prevalent during the month of March, 1883.

Including reports by regular observers, and by others, diphtheria was reported present during the week ending March 31st, and since, at fourteen places, and scarlet fever and measles each at seventeen places.

Typhoid Fever in Providence.—The increase of typhoid fever in this city within the last two weeks has given rise to considerable excitement, which has been increased by exaggerated and unreliable statements. We have obtained from the Superintendent of Health the facts, from which the following statement upon the subject is made. After the great prevalence of fever in November, amounting to an epidemic for a short period, the disease gradually decreased until, during the month of February, only half a dozen cases were reported. In the first half of March there were very few cases. From the 20th of February to the present time, April 7th, there have been seventy-five cases reported in all. Of these, the date of beginning was not given in six cases. This leaves sixty-nine cases. Of these, there were only fourteen which commenced from the 20th of February to the 20th of March. At the latter date there was a sudden and rapid increase, and in the eight days, from the 20th to the 27th of March, inclusive, forty-eight cases of the disease commenced. Nine cases were reported as commencing on the 25th of March. Since the 27th of March the disease has as rapidly decreased, and only seven cases commenced in the city from the 28th of March to the 7th of April, inclusive. None were reported as commencing in the last four days of last week.

In regard to the location of the disease, it has been generally the same as last fall, the greatest number of cases being in the southwest portion of the city.

It is probable that the disease has reached and passed its height, and is now on the decline; and that as the weather grows warmer it will cease. There is nothing in the facts thus far that would justify any panic on the subject; nothing that would warrant the exaggerated statements that have been made of the prevalence of the disease in certain portions of the city; nothing that confirms the theories so persistently promulgated, of the cause or causes of the disease.

Communicable Diseases in Michigan.—The State Board of Health has issued, in pamphlet form, that portion of its annual report for 1882 which treats of the diseases diphtheria, scarlet fever, and smallpox, for the restriction of which special efforts were made during the course of the year. As soon as information was received, officially or otherwise, of the existence of any of these diseases in a locality, the secretary of the State Board communicated with the local authorities, urging them to prompt action, and transmitting documents containing concise directions for carrying out the best methods of preventing the spread of the contagion. Special reports were received from 162 localities where diphtheria prevailed; from 82 places where scarlet fever was present; and from 61 places where smallpox had made its appearance. From the localities which reported diphtheria as present, a total of 1,206 cases were reported, and 296 deaths; but these figures are acknowledged to be below the actuality. The 82 localities infected with the scarlet fever poison reported 284 cases, and 48 deaths. Of smallpox, 589 cases were reported, 159 of which terminated fatally. In twenty-one instances, this disease was brought direct from Chicago; in several instances the importation was from Cincinnati; immigrants by the steamship "Cimbria" occasioned an extensive outbreak; immigrants introduced the disease also into Port Huron twice, and into Detroit twice; the first case, in Plainwell, was contracted in a paper mill. That the efforts of the State Board were productive of good, is very clearly manifested by glancing over the special reports. Commenting on the reports on scarlet fever, Dr. Baker says: "The vital statistics of this State show that for the five years just before the State Board of Health was established, the deaths returned as having occurred in Michigan from scarlet fever averaged 589 each year, and since then, only 412 each year; an apparent saving of 177 lives, on an average, for each of the seven years—1874–'80; or a total of 1,239 lives in seven years. Though more, perhaps, has been accomplished with scarlet fever than with diphtheria, it is believed that in the immediate future events will show, as a result of the work of this Board, a vast improvement in public opinion regarding diphtheria, and, consequently, a great saving in human life from loss by that disease.

State Board of Health, Michigan.—In the meantime the Legislature, in its wisdom, is considering the abolition of this Board (House Bill, No. 68). We are pleased to find, however, that the citizens have a better appreciation of the work of the Board. From the Legislative Journal of March 28th, we extract the following:

Whereas, No State service is of greater importance than one whose purpose is to gather statistics of facts to the end of securing a better knowledge of the causes of sickness, and of disseminating such knowledge among the people as will enable them to avoid such causes, and thereby save themselves the expense, suffering, and death that might not otherwise be avoided;

And whereas, The health service known as the State

Board of Health has done a great work to this end, and can still do more, it has become indispensable to the wants and welfare of our people. Therefore we, citizens of Reed City, State of Michigan, most earnestly request that you do your utmost to defeat House Bill, No. 68, so far as it relates, or any action hereafter that may cause it to relate, to the abolition of the State Board of Health, and any other measure intended to abridge its work and influence.

Referred to the Committee on Public Health.

DANGER FROM HAVANA.—From the 17th to the 30th of March, six vessels arrived at Charleston, S. C., from Havana, Cuba, with foul bills of health. They became infected with yellow fever during their stay in Havana, and lost twenty men by death from this disease, out of the sixty-nine which constituted the aggregate of their crews. No sickness occurred during the voyage, and none since their arrival at the Charleston quarantine station. This extent of disease in Havana so early in the season, appears to Dr. F. Grange Simons, Chairman of the Committee on Quarantine of the State Board of Health, to urge the need for special care, lest the disease be brought to our shores prior to the time when the stricter rules of quarantine are applied. Dr. Simons has notified these facts to the National Board of Health, and proposes bringing them before the State Board at its quarterly meeting, that suitable action may be taken.

PROPAGATION OF MEASLES.—In his bulletin for the week ending March 24th, Dr. P. H. Bryce, Secretary of the Provincial Board of Health of Ontario, Canada, refers to the exceedingly rapid spread of measles in six of the sanitary districts, and suggests attention to preventive measures. "Whatever the physical conditions are tending to propagate measles, it must be manifest to all that the total disregard in most cases for the isolation of patients affected with it explains how, being once present, its extension is carried on. Its infectiousness ought to be urgently called to the notice of all, since its contagiousness is fully developed by the second day of its invasion after some feverishness and catarrh are noticed, and two or three days before the rash appears; while the fact of the patient's unusually rapid improvement after the eruption is well out, makes it possible for the patient to spread the disease during his period of convalescence."

OBITUARY RECORD.—M. BISCHOFF, Professor in the University of Munich, well known by his many valuable works on embryology, has recently died, at the mature age of 75 years.

NOTES AND QUERIES.

HEITZMANN'S MICROSCOPICAL MORPHOLOGY.

To the Editor of THE MEDICAL NEWS.

SIR: In number 637 of the N. Y. *Medical Record*, I find a rather harsh and bitter criticism of C. Heitzmann's *Microscopical Morphology*, which, in justice to the author of an instructive, valuable, highly practical, and useful work, I desire, through the columns of your esteemed journal, to correct, especially since the anonymous critic has seen fit to cast a reflection upon me by mentioning my name among other collaborators of Heitzmann's laboratory in a manner which seems to indicate that I was not fully competent to write satisfactorily upon the subject of my study, published by the Academy of Sciences of Vienna, vol. lxxiii., which Professor Otto Frankenberg, of the Starling Medical College, of Columbus, Ohio, has kindly translated into English, and published in the *Ohio Medical and Surgical Journal*. An abstract of this appears in Heitzmann's book, pp. 504–510, inclusive, entitled "The Changes of Epithelia Produced by Growth of Myeloma."

Though I do not claim to be as world-renowned an histologist as the critic of the *Record* may be, from what I know, still I may say, without fear of contradiction, after many years of study, that I am able to see what is claimed by Heitzmann as the reticular structure of living matter, and that it is not, as the critic has it, the reticulum of cellular death, since everybody can see it in living amœbæ, in salivary and colorless blood, or pus-corpuscles, etc. Furthermore, I may add that Prof. S. Stricker, of Vienna, has recently corroborated the two main discoveries of C. Heitzmann. These are that so-called *protoplasm* has a *reticular structure* in a live condition, as proved in fresh saliva-corpuscles while alive and in motion; and, secondly, that the basis substance, or intercellular substance of Virchow, is likewise endowed with properties of life. In the face of this corroboration, I trust it is unnecessary to say more in defence of the correctness of C. Heitzmann's discovered and recently advanced theories. I am sure the critic will be willing to admit that in comparison with Stricker's authority, his bitter criticism deserves very little consideration from a scientific standpoint.

The critic maintains that America is ever ready to concede to Europe a well-earned preëminence as regards histology. Ten years ago this was perhaps the case, but now we have laboratories and teachers of histology in this country who have no superiors in in any university in Europe.

Finally, the critic advocates teasing, tearing, mounting of specimens in balsam, etc. By this he really shows that he yet depends upon some European teachers, and was not willing to change the methods which are to-day being admitted as improper ones in many of the histological laboratories abroad.

THE NEWS being read by most, if not all, of the readers of the *Record*, and many others, I thought I would request you to publish these few remarks of mine in refutation of an unjust and unjustifiable criticism of a good work, which, I think, deserves rather praise than fault-finding.

I am, sir, yours, very respectfully and truly,

RUDOLF TAUSZKY.

ORIGINAL LECTURES.

ON THE TREATMENT OF NEURALGIA.[1]

A Clinical Lecture

BY PROF. DUJARDIN-BEAUMETZ,

MEMBER OF THE ACADEMY OF MEDICINE, PHYSICIAN TO THE HOPITAL ST. ANTOINE, ETC., PARIS, FRANCE.

GENTLEMEN: Having finished the group of medicaments which have a direct action on the nerve or nerve-cell, we come to our second group, revulsive or substitutive medication, which sometimes gives remarkable results in neuralgia. This group comprises a variety of derivatives, from simple rubefacients to the most powerful escharotics.

First, then, frictions of the painful region have been advised; these to be more or less energetic; and, to render them more efficacious, it has been recommended to make these frictions with certain cutaneous irritants, and especially turpentine. In this category ought to be placed the celebrated remedy for sciatica of the policeman of Lyons, which consisted in enveloping the whole thigh in a Burgundy pitch-plaster, and which has cured some inveterate cases. In England, there is another popular remedy which consists in covering the painful limb with flowers of sulphur, and over the whole applying a firm flannel-bandage. Of still more general use is the mustard sinapism, which, in some cases of intercostal neuralgia, suffices to effect removal of the pain.

Next comes the vesicant, which is in current practice in the treatment of neuralgia. These vesicants may be of different kinds: sometimes the strong water of ammonia is applied locally till the cuticle is destroyed; sometimes the cantharidal blister, medicated or not with opium, is used.

In order to obtain relief with these blisters, they should be applied over the painful points. In sciatic neuralgia, I have been in the habit of employing a long, narrow blister, three centimetres in width and extending the whole length of the thigh; this blister is applied, as near as possible, over the course of the sciatic nerve. I can, from experience of its utility, recommend this as a most excellent mode of treating sciatica.

In other circumstances, when the neuralgia is more obstinate, it has been the custom to resort to cauterizations of greater or less depth. Legroux was in the habit of employing sulphuric acid; with a stick soaked in the strong acid, he marked out on the painful member the branches of the sciatic nerve. This method is a severe one, and is no longer employed; but instead we use the hot iron, and in particular the Paquelin cautery; with this cautery, points are made all along the nerve. If you prefer transcurrent cauterization, you lightly brush the skin covering the nerve or nerves affected with the Paquelin cautery, heated to a white heat. These cauterizations are a powerful means of cure, and, being little painful, you can always resort to them when other means fail.

In order to act still more directly on the diseased parts, it has been proposed to penetrate to some depth into the tissues, and this is what has been realized by acupuncture. You know the use that has been made of acupuncture in the far east—it was there that we learned the manner of performing it; this revulsive method which was much in vogue at the beginning of this century, owing largely to the labors of Jules Cloquet and Dantu of Vannes, is now altogether abandoned. The principle, however, has been adopted by Baunscheidt in that little invention of his called *réveilleur de la vie* [life-awakener], and sold by our instrument-makers under the name of *Baunscheidt's Dermabioticon*, which, twenty years ago, excited so much enthusiasm. This instrument consists of a bunch of pins which are made to penetrate the skin by a spring, and, in order to give a more intense revulsive action, the pins are dipped, before using, in croton oil, or in a highly irritant mixture which Baunscheidt devised, of equal parts of oil of black pepper and oil of mustard. Baunscheidt's "Life-awakener," with its accompanying oil, has had a great celebrity in the treatment of sciatica, but is rather a thing of the past than in actual use at the present day.

A modification of acupuncture, electro-puncture, much used by Magendie with galvanic currents in the treatment of neuralgia, has also had its day, and is now abandoned. Medical electricity has, however, utilized these acupuncture needles in galvano-thermy, which is one of the most powerful revulsive methods that I know of, and the excellent effects of which I have seen in my own service and in that of my friend Perier. This operation is performed with the condenser of Planté, appropriated by Trouvé to medical practice; with a wire heated to a red heat by electricity, points are made to the depth of half a centimetre, and some little distance apart, over the tract of the affected nerve. The punctures are followed by considerable inflammation, but they often bring the greatest relief to the patient.

I need only glance at another method of making punctiform eschars, a horribly painful method, now happily gone out of fashion. I allude to *aquapuncture*. A filiform jet of water is projected by means of a force-syringe with such violence upon various points of the affected nerve that the skin is perforated, often to the depth of several millimetres, in many places. Siredey is responsible for the vogue which this method has had.

Luton's mode of treatment of sciatica is based on the same principle, though the manner of application is different. The Professor of Rheims has proposed to introduce by the hypodermic syringe certain irritating substances, as nitrate of silver, which are injected over the painful spots. The caustic solution is made with one part to ten, or five. These irritating injections determine an artificial anthrax, which results either in induration of the tissues or in abscess. The partisans of this revulsive procedure claim signal success in its use. Out of Luton's fifty cases of sciatica, forty-eight of them are reported permanently cured. Rupaner (of Boston), Bertin, Le Dentu, Damaschino, Gerin Rose, Dureau, and Angelé, all report good results from this operation, which Luton, the inventor, has designated as "subcutaneous injections for local effect." It cannot, however, be maintained that the operation is altogether certain or safe, and troublesome sequelæ have resulted, and are likely to result, from these irritating injections.[1] In certain cases, instead of

[1] Translated from advance sheets by E. P. Hurd, M.D., of Newburyport, Mass.

[1] These injections, first introduced and popularized by Luton, in 1863, are chiefly of use in that most rebellious of neuralgias—

making the cauterization over the painful point, it is made at a distance; and we have seen Jobert cure sciatica by cauterizing the lobule of the ear. Even at the present day, there is sold, under the name of *Indian Remedy*, an irritating substance which is designed to be introduced into the auditory canal, and which is believed to act beneficially in the treatment of odontalgia.

To finish the consideration of the external medication of neuralgia, I shall simply allude to massage, or rather what has been described under the name of *Kinesitherapy*. In the treatment of this disease, massage is now much used, with its various methods, kneading, pinching, and percussion; Schreiber has lately insisted on the advantages of massage in neuralgia and in muscular rheumatism.[1]

I have finished the long enumeration of the more important measures which constitute symptom-medication, and whose object is the relief of pain. It remains for me, in order to complete this subject, to speak of the empirical means, whose mode of action in the treatment of neuralgia is thus far unknown; and I am going to allude to turpentine, phosphorus, guarana, and sulphate of copper.

Turpentine, which, as I told you, is sometimes used in embrocations and liniments in this disease, has also been given internally; and Martinet and Trousseau have prescribed, in sciatica, capsules of essence of turpentine, six or eight to be taken every day. It is possible that some cases of sciatica may have been cured in this way, but turpentine readily disorders the digestive functions, and is often badly tolerated, hence is little used as an internal remedy.

Phosphorus has been the most often employed in England and America in the treatment of neuralgia. This use of phosphorus is altogether empirical, and although we have seen that protagon, the proximate constituent of cerebral substance, contains a notable proportion of phosphorus, no direct relation has as yet been established between the functions of the cerebro-spinal axis and the presence in the nervous tissue of a greater or less quantity of phosphorus. However this may be, Thompson, in England, and W. A. Hammond, in the United States, have highly recommended its use.

Phosphorus is given in two ways, as phosphorated oil and as phosphide of zinc. [In this country the pill-form is generally preferred, each pill representing $\frac{1}{100}$th grain; one or two of these pills three times a day.—TRANS.] Phosphorated oil is administered in capsules containing one milligramme of phosphorus; beginning with one capsule, and gradually increasing to ten capsules, three times a day. Phosphide of zinc is an excellent form for administration of this medicament. This phosphide readily undergoes decomposition in presence of the acids of the stomach, yielding up its active principle. In connection with a former pupil, Proust, one of the victims of the late Franco-Prussian war, I made quite a thorough study of these metallic phosphides, which had lately been introduced into therapeutics by Vigier, and our experimentation showed that we might profitably utilize in medicine many of these compounds. Phosphide of zinc is given in pills of four milligrammes (about $\frac{1}{15}$th grain), this represents one milligramme of phosphorus. From one to ten of these pills may be given a day. I shall return to phosphorus-medication when I come to speak of chronic myelitis; as for its results in the treatment of neuralgia, in my experience they have been simply *nil*.[1]

Guarana, or paullinia, has been recommended for neuralgia, and especially for megrim. This substance, as you are aware, comes to Europe in the form of cakes made by drying a paste of the seeds of *Paullinia sorbilis*. The latter is a climbing plant belonging to Brazil, of the family Sapindaceæ. Besides gum and starch, fatty matters, and tannin, it contains caffeine in notable quantity, which latter is the active ingredient. The guarana may be given in powder for migraine; dose, one or two grammes stirred into a little water, before or during an attack. Caffeine may be given instead, in the dose of twenty-five to fifty centigrammes. This medicament has an action which is often decided, though of short duration.[2]

Ferreol has of late recommended ammonio-sulphate of copper in the treatment of stubborn cases of neuralgia of the face. This medicament, whose *modus operandi* is unknown, may possibly act in accordance with Burq's theory of metallotherapy. It is given in potion in the dose of ten centigrammes a day, or (what is the better way) in capsules containing two centigrammes; five to ten of them being given daily. (The results have not been very favorable.)

(To be concluded.)

sciatica. They are made just behind the trochanter major, towards the inferior border of the gluteus maximus. The injection is made into the subcutaneous cellular tissue, and with varying doses of a solution of nitrate of silver, one part to five, of which from fifty centigrammes to one gramme may be used at one time. In rheumatic sciatica, Gerin Rose injects six cubic millimetres of the following solution, which contains one part to fifteen: R.—Argent. nit., grm. .50; Aquæ dest., grm. 7. M. He seeks the most painful point, which is generally where the nerve issues from the pelvis at the great sacro-ischiatic foramen, and plunges deeply the Pravaz needle so as to penetrate the cellular tissue into the muscular interstices, in which (providing no blood wells up through the needle, making its appearance at the proximal end), after having adapted the syringe, he slowly injects, drop after drop, the solution. The second day, a phlegmonous tumor as large as the fist forms over the site of injection; this, however, rarely suppurates, but disappears by resolution. Gerin Rose has been successful in thirty cases, and has witnessed no troublesome sequelæ.—Luton, *Des injections sous-cutanees a effet local*, Paris, 1875. Blosart, "Treatment of Chronic Sciatica by Injections of Nitrate of Silver," *These de Paris*, 1872. Angelé, "Treatment of Neuralgia by Irritating Injections," *These de Paris*, 1878.

[1] Bull. de Thér., t. cii. p. 276, April 15, 1882.

[1] In this place *tonga* deserves mention, a remedy for neuralgia introduced to the profession by Sidney Ringer and Willlam Murrell, of London, in 1880 (*vide Lancet*, March, 1880), and obtained from the Fiji Islands. It has long been used by the South Sea Islanders for all cases of neuralgia. It is employed in the form of alcoholic extract, in the dose of a teaspoonful every six hours. Its effects seem to be very similar to those of guarana.

[2] Introduced into New England about the year 1870, and long sold at fabulous prices. No remedy has given more general satisfaction in the treatment of migraine than paullinia, and the effects have generally been as lasting as those of any other remedy. The following formula by the late Dr. George M. Beard, has done good service:

℞.—Citrate of caffeine,
Carbonate of ammonia, . . . āā ℈j.
Elixir of guarana, ... ℥j.—M.
Sig.—Dose, a teaspoonful.—TRANS.

ORIGINAL ARTICLES.

A NEW ABDOMINAL OPERATION.

"DIGITAL DIVULSION OF THE PYLORUS," DEVISED AND SUCCESSFULLY PERFORMED BY PROF. PIETRO LORETA, OF BOLOGNA, ITALY, FOR THE CURE OF STENOSIS, RESULTING FROM THE CICATRIZATION AND CONTRACTION OF SIMPLE OR NON-MALIGNANT ULCER OF THE STOMACH, INVOLVING ITS PYLORIC ORIFICE.

BY ROBERT P. HARRIS, M.D.,
OF PHILADELPHIA.

(Reported by request.)

THIS new Italian operation has been now performed four times in six months. The first and

second cases, as shown by excellent photographs sent me by Dr. Domenico Peruzzi, of Lugo, have made good recoveries; and the fourth operation, in which he was an assistant, was too recent, when he wrote, to decide as to its prospective result. By the desire of Dr. Peruzzi, I here present the subject of this form of operation to the medical profession of the United States, a record of the first two cases having been furnished me in a twenty-two page quarto pamphlet, the contents of which were read by the operator before the Academy of Science of the Institute of Bologna, on February 11, 1883.

We are not to confound this operation of Loreta with that of resection of the pylorus, which has very little to recommend it, even as an expedient for temporarily prolonging life; and nothing, in view of the hope of an ultimate recovery; or with the more recent and promising one, of exsection of chronic ulcer of the stomach, although the risk may appear to be hardly justified by the immediate danger to life from the disease to be removed. But in the cases for which Prof. Loreta has devised his operation, there is the prospect of certain death by starvation and exhaustion, unless the mechanical obstruction is removed; and of recovery of health, with the reopening of the pyloric orifice, there being nothing in the nature of the disease rendering it incurable, as in the stenosis from cancer.

The dangers from "simple" ulcer of the stomach arise from perforation of the viscus; erosion of its arteries; adhesions and contractions of its walls; and *closure of the pylorus*. The last is a rare result, but the fact that three cases have come under the observation of a single surgeon in six months, shows that the operation for its relief is not an unimportant one. According to the observations of Dr. William Brinton,[1] the seat of ulcer of the stomach is at its pyloric extremity in sixteen per cent. of the cases; but the destruction of tissue, in a way to produce obstructive constriction under the process of healing, must be exceedingly rare in Great Britian, as he does not mention this stenotic result as an element of danger to the subjects of the disease. The experience of our own physicians is also in corroboration of that of Dr. Brinton. It is true that he does say of the ulcer that, "*in rare instances*, it forms a zone around the pyloric valve, or the pyloric sac," and we may imagine what would be the result of the cicatrization of such a lesion. He also remarks, that the healing of an extensive ulceration may seriously affect the shape and capacity of the stomach, giving it more or less of an hour-glass form, and that "in extreme cases the contraction amounts to an absolute stricture, which impedes the transit of food, and thus gradually causes great hypertrophy and dilatation of the over-distended segments of the stomach behind the obstruction;" but still he does not mention the possibility of cicatrization producing a fatal stenosis of the pylorus. In Italy, where pelagra affects 100,000 of her peasantry, due, it is thought, to the defective assimilation of an unhealthful diet, and the bad hygienic conditions under which they live, it is quite possible that pyloric obstruction may be less rarely met with than in England and America, and the operation of Loreta more frequently called for.

We are also to distinguish between the stenotic condition produced by the healing of an ulcer of the pylorus, and that resulting from a hypertrophic thickening of the valve, called by Habershon "fibroid degeneration of the pylorus." This cirrhotic infiltration, which has been attributed to a chronic interstitial gastritis, can only be distinguished from true cancer under the microscope, and differs very little from it as a mortal malady. Having examined this very rare disease post-mortem with a great deal of care, I cannot see that any operation for opening the pylorus, even where the disease may be confined to it, could be of any practical utility, any more than it would in a case of pyloric cancer. The operation of Prof. Loreta must, therefore, be confined to the form of stenosis produced by cicatricial contraction of the gastro-duodenal opening, a condition which can only be determined by a careful study of the history of each case, taken in connection with the evidences elicited by a cautious physical exploration. Fortunately for the cause of science and humanity, the first and second operations were successful. Had there been any error in diagnosis, requiring that the operations should not be completed, it is probable that the patients would have recovered from the exploratory incisions, as such an amount of abdominal traumatism need not, at the present day, be regarded as *very* dangerous. We now come to the record of the initial operation, as performed at Bologna, which want of space compels me to give in a very reduced form, as compared with the original report.

Case I.—Nicola Cecconi, born in Italy, of healthy parents, a railroad operative, aged 47, always enjoyed good health until the year 1863, when, at the age of 27, he received a severe blow in the epigastrium, after which gastric troubles commenced, manifested by imperfect digestion, a feeling of weight and distention in the stomach, and occasional attacks of vomiting. He continued, however, to labor and was able for some years to bear up against his dyspeptic condition; but in 1878 was obliged to apply to the Medical Clinic of Bologna for relief, his disease having slowly become more severe in character, the sensation of weight being changed to one of pain, and his vomiting being no longer simply of alimentary substances and mucus, but of blood also, at times freshly poured out and bright red, at others partly digested and blackish. He suffered also with many intestinal troubles, and, as always happens in this class of diseases, with constipation alternating with diarrhœa: he became finally pale, thin, feeble, and low spirited. The physician who had him in charge gave the diagnosis of "round ulcer of the stomach in the region of the pylorus," which was confirmed by the result of treatment, his health being restored after a residence of three months.

When he left the hospital he was so much improved that he went home in good spirits and resumed his work on the railroad. This soon brought

[1] Lectures on the Diseases of the Stomach, page 133. London, 1864.

back some of his gastric sufferings, manifested by the sensation of weight in the epigastrium; the phenomena of indigestion, such as eructations, burning sensations, and acidity. Then his attacks of vomiting were renewed; undigested food being thrown up, followed by a sense of relief for some days, when there would be another attack. These symptoms in time became augmented in intensity and duration, so that by the summer of 1882, when Prof. Loreta's attention was called to his case, he was brought to a very pitiable condition of suffering, his only food being a little milk, which he retained for about half an hour before vomiting it; all other articles of diet being immediately rejected. He had formed an impression from his own sensations, that no food passed beyond a point in the right hypochondrium.

When admitted for final treatment in the "clinic," Cecconi presented a pale, emaciated appearance, and two days before the operation was reduced to a weight of 121 pounds. His abdomen was swollen in the epigastrium, where there were presented the evidences of dilatation of the stomach, palpation giving a sense of tension and elasticity, and percussion the clear resonance indicative of an accumulation of gas, the tympanitic region extending from the fifth rib to the umbilicus.

Fluid extracted by the stomach-pump presented a yellowish color, and contained small coagula of milk; it quickly reddened litmus paper. Left to stand, it soon separated into three strata, of which the upper was composed of frothy mucus, the middle of limpid whey, and the lowest of a substance having the character of a gray powder.

Under the microscope there were found no muscular fibres, no trace of *sarcinæ ventriculi*, no granules of starch, and no needles of fatty acids.

The pump was also made use of, to empty the stomach, so as to render it flaccid, but in this condition no evidence of the existence of a tumor could be detected in the abdominal cavity, other than a thickening at the pyloric end of the stomach. This growth was not well circumscribed, or nodular, but offered under palpation the characters which belong to "an organized phlogistic exudation," or hypertrophy of the pylorus. It was not regarded as cancerous, because the history of the case, the duration of the disease, and the condition of the man, were not indicative of the presence of this malignant growth; neither were there any marks of cachexia, or of the mechanical dropsy of thrombosis.

Prof. Loreta, bearing in mind the diagnosis given of Cecconi's case in 1878, its subsequent progress, and the fact that *Kleef, of Maestrict*, had resected a stenotic pylorus from a woman of thirty-seven, in which the closure was due to the cicatrization of a chronic ulcer; decided, in view of all the points presented, that the case before him was of the same character with that of Kleef, whose form of operation he did not follow, because of the great mortality of the method; he therefore devised a less difficult and dangerous measure of relief, and one requiring far less time in its performance.

The operation was performed on Sept. 14, 1882, under chloroform; the incision commenced to the right of the linea alba at a distance of 4 cm. (1½ in.) from the xiphoid cartilage, and was carried obliquely downward and outward for 15 cm. (6 in.) to a point 3 cm. (1¼ in.) from the ninth costal cartilage. Some arteries required ligation, and time was given for hæmostasis of the edges of the wound before opening the peritoneal cavity. This was not readily distinguished, because the gastro-colic omentum was united by old adhesions to the abdominal walls. These adhesions required to be slowly and carefully separated; after which others were found between the omentum and stomach, requiring the same treatment. These adherent parts had masked the examination of the pylorus, and produced, under palpation, the sensation of the existence of a morbid deposit occupying the epigastrium and right hypochondrium.

When the stomach was liberated from its adhesions its pyloric extremity was drawn out, and an incision made into it between, and at equal distances from, its two curvatures, commencing 3 cm. (1¼ in.) from the pylorus and extending 6 cm. (2⅜ in.) in length. The edges of this wound bled freely, and required compression with T-shaped pincettes. The index finger of the right hand was then introduced, and the pyloric opening found to be entirely closed up. By a careful rotation, with pressure and counter-pressure, one index finger was made to penetrate the pyloric valve, and after a time that of the other hand also. The fingers were set back to back, and an attempt made three several times by the operator to stretch the opening; but such was the amount of resistance on the part of the sphincter that he failed to accomplish his purpose. After a time, however, the parts began to yield, and the fingers were gradually separated until the pylorus was widely opened without any laceration. The operator in describing this, says that his fingers were separated to "a distance of about 8 cm.," which would give a circuit to the opening of about 9 inches. This must be an error, as the opening into the stomach made by the knife had but a circuit of 4¾ inches, which would limit the separation of the fingers to that extent, as the sphincter was but 1¼ inch from this opening.

With the pincettes still applied, the wound of the stomach was stitched up by the uninterrupted suture of *Gely*, which may be found described in the surgical work of Prof. Gross. Carbolized silk was used, with a needle at either end, and the first stitch made at the end of the wound nearest to the pylorus, a centimetre from it, and the punctures each a centimetre from the edges of the incision. After this wound was secured, that in the abdomen was closed with seven sutures of silver wire. In thirty-three minutes from the commencement of the abdominal incision the operation was completed and dressings applied.

The convalescence of Cecconi was a remarkable one, both from the operation and his prior condition: he suffered no pain during the operation, and gastric tolerance was reëstablished with the removal of the mechanical obstruction. On the evening of the day of the operation his temperature was 43°

Cent. (98.6° Fahr.), pulse 72, and respiration 26: he became hungry in the middle of the day, and was given the yolk of an egg with some Marsala wine; and every half hour he was allowed a tablespoonful of coffee, all of which he bore well.

The highest temperature recorded after the operation was 38° C. (100.4° F.), pulse 76, and respiration 26. On the fourth day his bowels were moved by enema. On the fifth day he experienced some pain and inconvenience from the passage of gas in the intestines, and possibly of food through the pylorus. On the sixth day he ate some roast chicken twice, and on the seventh had a natural evacuation of the bowels. The first dressing of the abdominal wound was made at the expiration of eight days, and five of the seven sutures removed, the parts having healed by the first intention; the other two sutures were taken out two days later. The patient was out of bed for two hours on the seventeenth day, and by October 30th (46 days), had gained in weight 13½ pounds, increasing from 121 pounds to 134½ pounds.

On October 12th, Cecconi was discharged cured, a result which a probation of five months has only more satisfactorily proved.

Case II.—Cesare Frabetti, 18, a native of Italy, suffered with dyspeptic symptoms from the age of eleven years, his mother being a victim of the same disease. He first vomited bread, which he had eaten in too large a quantity at the age given, after which he vomited more or less every day. Finally, he presented the decided symptoms of chronic ulcer of the stomach, having severe pain in the epigastric region and hæmatemesis. Early in December, 1882, Frabetti came under the observation of Prof. Loreta; he presented the physical signs of a dilated stomach, with an area of clear resonance equivalent to that given in the record of Case I. He vomited twice daily, and the fluid evacuated had the same characteristics as that noted in Cecconi's case. Every ten or twelve days he had a very small evacuation from the bowels; and his urine was normal in quantity, but pale and unusually fluid. In appearance he was pale and thin, feeble, and had an expression of melancholy.

Examined by the carbonic acid gas test of *Ebstein*, there was no evidence, when the stomach was distended, that any gas escaped through the pylorus. The evidences from examination of the fluid contents of the stomach chemically and under the microscope, and from palpation and percussion of the abdomen, were in favor of the disease not being of a malignant type. In fact, no morbid growth could be discovered in the pyloric region or elsewhere.

The operation was performed after the manner of the first one on December 22, 1882, but required in all fifty minutes, owing to a difficulty in locating the exact position of the pyloric valve. The stomach was sutured after the process of *Appolito*, which proved to be more quickly executed and equally efficacious as compared with that of *Gely*. One-half of the time of the operation (twenty-five minutes) was taken up in a patient search after the pylorus, which was opened to the extent of separating the fingers 5 or 6 cm. (2 to 2⅜ inches). In the stomach were found two plum-stones, which it was computed had been retained for two years, as the patient had been made to suffer so much by the last he ate, that he had not eaten any since 1880.

Frabetti, like Cecconi, had no febrile disturbance after the day of the operation. He was sustained by a milk diet, and consumed large quantities with impunity. In four days the intestinal circulation was reëstablished. The sutures were removed on the ninth day, and the patient was out of bed on the fifteenth day. At the time of the operation he weighed eighty-nine pounds, and in thirty-eight days he had increased this to one hundred pounds. Fifty days after the operation Frabetti was regarded as having been restored to entire health, which his photograph bears the evidence of in the expression of his face and contour of body.

Judging from the number of cases of *dilatation of the stomach* (gastroëctasia) existing in Europe, as shown by Kussmaul, Bernheim, Petrequin, Thiébaut, and others, a disease which is generally independent of pyloric stenosis; it is quite possible that the form of disease operated upon four times in Italy, may prove to be more common than might be supposed.

Note.—After the preceding was in type, I received, through Dr. Peruzzi, an account of the two additional cases, one of which he saw and reported, writing a short record of the operation for the *Raccoglitore Medico* of March 20, 1883, on the day of its occurrence, and subsequently completing the same in writing to me, so as to give its final result, which will be seen under "Case IV."

Case III.—The subject of the operation was a woman (age not given), who was much exhausted from compulsory fasting, due to her inability to retain food, the result of pyloric stenosis. She was operated upon, at the Hospital of Cesena, Italy, by Dr. Mario Giommi, on February 1, 1883, and, owing to her prior condition, died of *shock* in twelve hours.

Case IV.—This was previously referred to as the third operation of Prof. Loreta, and the one in which Dr. Peruzzi assisted him. The subject was a man, of forty-six years of age, who, like Cecconi, was a workman on the Southern Railroad of Italy. He was operated upon at the "Surgical Clinic of Bologna," on March 17, 1883, but in a physical condition much less promising than that of Cecconi or Frabetti. He had been the subject of chronic gastritis for seventeen years, and was emaciated, weak, and scarcely able to speak. The operator's diagnosis was *pyloric stenosis*, as the result of chronic pyloritis. He made the incision as in his first operation, and six inches in length, and opened the stomach to two and three-eighths inches. After sufficiently enlarging the stenosed pylorus, he closed the incision in the stomach by the suture of Appolito, as in his second operation, and dressed the abdominal wound after the manner of Lister. The operation, from the commencement to the closure of the abdomen, required twenty-eight minutes. The patient died of *shock* in thirty-seven hours; his condition prior to the operation giving but little hope of a favorable result.

An autopsy was made in this case, the result of which will be given in the *Raccoglitore* of March 30th.

Here we have four operations performed by this new method, for the relief of pyloric stenosis, in a period of 184 days; showing that the condition of disease under treatment may be a comparatively common one in Italy: hence the value of digital divulsion in the estimation of the colleagues of Prof. Loreta, who are very complimentary in their praises of his ingenuity and originality in devising a plan of relief which promises excellent results, where the patients are not too much exhausted and emaciated before the operation. The first two cases are far better tests of the value and risk of the operation than the second two, whose deaths were almost a necessary result of gastrotomy performed *in extremis*. All honor to Professors Porro and Loreta for the reputation which their operations have brought to themselves and to Italy. Possibly the Loreta operation may have a future in Europe, which will make the name of its originator as famous as seven years' experience has made that of his Pavian colleague, whose "*utero-ovarian amputation*" was not performed four times, until near the close of its first year of probation, and not repeated by Prof. Porro himself for nearly seven years. The second success of his operation was in the fifth case; the third in the ninth; the fourth in the twelfth; and the fifth in the sixteenth. With favorable conditions for the operation, the method of delivery devised by Prof. Porro may be reasonably expected to save fifty per cent. of the women and eighty per cent. of the children, as it has done in Italy during the last four years, counting all the cases both hospital and private.

Thus far the Loreta operation has saved one-half of the cases; and judging from the registers of temperature, pulse, and respiration in the first two, and the rapid restoration of the powers of digestion, it cannot, *per se*, be a very dangerous one. Cases such as Nos. 3 and 4 can hardly be expected to survive the operation in the condition of prostration under which it was performed. Because patients do sometimes recover most unaccountably after abdominal operations, as I have a number of times seen, we must not look too confidently for such results where the subjects are in an unfavorable condition by reason of delay and loss of vital force. It strikes me that in the great improvements that have been made in rectal alimentation, it would be much safer in a case like No. 4 to prepare the patient for the operation by a course of bowel-feeding rather than run the risk of giving him the *coup de grâce* by the knife in his starved state. These cases differ in one respect from all other cases in which abdominal surgery is required for the saving of life, as the condition is simply mechanical and the result of a previously existing but healed lesion. There is no diseased tissue to be cut out, and time is not necessarily lost by emptying and resting the stomach, and nourishing the patient by the bowels. A test of a few days will suffice to show whether or not this is sound advice.

The safety of the gastric wound is largely due to the method by which it is sutured. The mucous coat is not to be penetrated. The best material is pure silk, *i. e.*, free from color, and sea-island cotton. The object of the form of closure is to make a perfectly water-tight one, and to bring peritoneal surfaces together to secure a rapid union. This is done by inverting the edges of the wound, and bringing its serous surfaces in apposition. The continuous suture of Gely does this perfectly, and there is but one knot when it is tied; the stitches are taken parallel with the line of incision, and after each pair are inserted through the peritoneal and muscular coats by two needles carrying one long silk ligature, they are crossed each to the opposite side for the next pair of stitches, and the silk left slack between. When all are taken, the pincettes are removed, and the loops of silk drawn in order, to the last, which is tied. This shuts in the silk and knot, and throws up a long ridge on the inside of the stomach; any water-pressure shuts the lips of this ridge tighter together, and no gastric juice or liquid food can escape into the peritoneal cavity. This stitch may be modified and made more simple of execution, but the same principle of action must be followed to secure an equally favorable result. There is no better suture than that of Gely, and not one in all respects as perfect, but there are others which will secure a water-tight closure with less time and delicacy in execution.

329 SOUTH TWELFTH STREET,
April 12, 1883.

TWO ORTHOPEDIC CASES.

BY AP-MORGAN VANCE, M.D.,

ORTHOPEDIC SURGEON TO KENTUCKY INFIRMARY FOR WOMEN AND CHILDREN, AND LOUISVILLE CITY HOSPITAL.

(*Read before the Kentucky State Medical Society, April 5, 1883.*)

CASE I. *Buck's Modification of Barton's Operation for Angular Bony Anchylosis of Knee-joint.*—In August, 1882, Mr. W., æt. 24, called on me for advice concerning a deformity of the right lower extremity, giving history of the trouble as follows: When about six years old, while at play, he received a blow on his right knee which caused considerable pain, followed in a few days by swelling and flexion, preventing the use of the limb.

He was treated by various surgeons, who attempted to overcome the deformity and subdue the inflammation, and about ten or fifteen years ago the limb was forcibly straightened.

Renewed inflammation, with abscess ensued, the limb soon assuming the position in which I found it, flexed at an angle of 90°. Several pieces of bone were discharged or removed by surgical interference, when the inflammation subsided. Since then he has walked by aid of a crutch with a stirrup on it. Upon examination the limb was found flexed at an angle of 90°, perfect bony anchylosis having taken place; the femur had become bowed anteriorly from the prolonged force brought to bear upon it in walking, the leg below acting as a powerful lever. Several cicatrices were found about the site of the joint. The limb was much atrophied, though the muscles acting between pelvis and thigh were well developed. The foot was in slight calcaneo-valgus, though there was left good action of the extensors.

The patient wished very much to have his limb straightened, and after discussing the various procedures by which this could be done, and after consulting other surgeons, it was decided that the operation known as Buck's modification of Barton's operation should be done.

Fig. 1.

This consisted in the removal of a wedge-shaped piece of bone sufficient to compensate the angle of deformity, part of the condyles of femur and tibia, as well as the patella being included in the wedge.

September 27.—The operation was performed; Drs. Cecil, Murrell, Thomson, and Thum, assisting. Fig. 1 represents limb before operation.

The patient was in fair general condition, though somewhat nervous from anticipating the ordeal through which he was to pass.

An apparatus to receive the limb when straightened had been prepared, consisting of a leather hammock for the thigh, and one for the calf, connected by bar-iron in such a way that the knee would be exposed when applied. A foot-piece was attached.

In this appliance the limb could be fixed in its new position. The patient was chloroformed and the operation commenced by estimating where the apex of the wedge should come, and marking it on either side with silver pins. An elliptical piece of skin was quickly dissected off from pin to pin about one-half the size of the base of the wedge of bone to be removed.

An ordinary amputating saw was inserted a little below the upper border of the patella, and directed towards the pins on either side; then started through the tibia for the same points. The wedge was easily removed. Just at this point in the operation the patient was overcome by the anæsthetic, requiring a cessation of work at my end of the table, and very active efforts at the other. By changing the chloroform for ether, and administering brandy hypodermically, and amyl by inhalation, the patient was revived sufficiently to proceed with the operation, which was done with the greatest rapidity.

When it was attempted to bring the bony surfaces together by straightening the limb, the hamstrings, which had seemed very lax, prevented the straightening process to more than a few degrees.

They were quickly divided subcutaneously, and using considerable force the surfaces were brought into apposition, fitting perfectly. Before doing this, a skein of silk was grasped in a pair of dressing-forceps and carried through the popliteal space from above, an incision being made to it through the skin from below. This did not prevent apposition of the bones, and would act as a guide to the pus that was expected. The skin-wound was closed smoothly by interrupted sutures, the limb, enveloped in absorbent cotton, was fixed in the apparatus, and the patient placed in bed.

The operation consumed thirty minutes; considerable shock followed. After twenty-four hours, a coil of rubber tubing was placed around the knee, extending several inches above and below the incision, through which ice water was kept constantly running. The dressing was untouched for ten days, the limb being closely watched to ascertain the formation of any great amount of pus.

When the dressing of absorbent cotton was removed, the skin wound was healed through its entire extent, except where prevented by the drainage silk, and at the external angle which had been left unclosed to permit drainage. The stitches were removed, and the silk drawn through the skin above, and left hanging from the lower opening for a few days longer. Very little pus was formed during the whole time.

At the end of three weeks a plaster dressing was substituted for the open dressing, with absorbent cotton next the limb to take up any discharge issuing from the lower opening, now nearly healed.

After this the patient moved about on crutches, and two weeks later, on removing the dressing, to our surprise bony union was found perfected, the wound being completely healed. The patient's general health had suffered very little, his temperature never rising above 100° F.

The only difficulty experienced was from the confined position during the first two weeks. After that time he was in a reclining chair.

A high shoe was made, and at the end of the seventh week he walked several times across my office, and a week later a photograph, the original of Fig. 2, was taken, on which occasion he walked very well, several times across the gallery, by simply steadying himself with the crutch used us a staff. He felt a little trouble from the tenderness of the bottom of the foot, that for so many years had not been used in walking. I believe that he will walk with

ease without aid from cane or crutch, the two and three-quarter inches shortening being compensated for by a high shoe.

Fig. 2.

In 1826, Dr. John Rhea Barton of Philadelphia, performed the first operation of this kind, the removal of a wedge of bone to compensate for an angle of deformity. In this case the wedge was removed from the upper end of the femur, the bone being anchylosed at an angle of 90°, and adducted. The patient, a sailor aged twenty-one years, made an excellent recovery, with a false joint, motion having been kept up for this end.

In 1835, Dr. Barton modified this operation in a case of angular anchylosis of knee. The patient was a medical man, and a good result was obtained. The wedge was removed from femur as near knee as possible, the apex posterior, and the limb straightened.

Fourteen cases of this operation were performed, with two deaths—one from hectic irritation, the other from exhaustion.

In 1844, Dr. Gurdon Buck, of New York, modified Barton's operation by taking the wedge through the site of the joint, including in the wedge part of the condyles of femur, tibia, and patella, as was done in the case I report. Dr. Gross has gathered twenty-one cases of this operation, with four deaths from pyæmia.

Case II. *Neurectomy of Anterior Tibial for Cure of Chronic Neuritis; Achillotomy at same time to Relieve a resulting Club-foot.*—On March 8, 1883, Mr. S., æt. 34, of Mississippi, came to me for advice concerning a painful trouble about right ankle-joint, giving the following history: Family history good. He had never been sick, with the exception of one attack of remittent fever, until the occurrence of the accident which caused the present trouble. Seven years ago, while walking down a declivity, in a pair of boots with very high heels, his right foot turned. Great pain and swelling ensued, and a physician told him the small bone of the leg was broken, yet no dressing except an ordinary roller was applied. He was unable to use the foot for eleven months, suffering much pain during that time. After that he was able to get about with a cane, till two and a half years since he repeated the same accident in an aggravated manner, causing intense suffering, the pain being referred to anterior aspect of foot, about annular ligaments, and to the toes. This pain had been unremitting until he called on me, despite the use of all manner of local and general treatment.

For some time he had, by order of his physician, taken opium *ad libitum*, to relieve the constant pain.

His object in coming here was to have the foot amputated if necessary.

Upon examination, the patient was found in poor condition; had lost much flesh; without appetite, and very nervous. He had ceased the use of opium for six weeks, against the advice of his physician.

Local examination revealed a much atrophied limb, the foot being in complete equinus. The whole anterior surface of the foot was exquisitely tender; the tenderness being greatest about annular ligament, over course of tibial nerve extending along nerve trunk, halfway to knee; any effort at voluntary or passive flexion of foot greatly increasing pain. No swelling or evidence of former fracture was present.

A number of blue spots over foot and leg were present from recent blisters, used, the patient said, "to draw the pain away to a new place." I diagnosed, by exclusion, chronic neuritis of anterior tibial, and advised the removal of a section of the nerve, far enough above to ensure immediate relief of pain, and sufficiently extensive to prevent its very early renewal of function, if this should ensue. The division of the tendo Achillis, at the same time, was advised, followed by mechanical treatment to restore the foot to normal position. Dr. J. W. Holland, who saw the case with me, confirmed my diagnosis, and proposed treatment. On March 10th both operations were performed in the presence of Drs. Holland and Murrell, and Dr. Cheatham, who administered the ether.

The incision was made as for ligation of the artery in its lower third, the nerve easily exposed, and an inch of it removed, the wound closed and simply dressed with absorbent cotton and blood.

The tendon was then divided, and gradual force immediately applied to overcome deformity, the counter-force pressing directly over the part of the foot which had been so intensely tender.

At the end of three days the stitches were removed. The wound had healed through its whole extent. The foot was in normal position, and voluntary flexion could be carried to almost normal extent. The moving of the flexor tendons about the

wound caused slight irritation, and a small amount of pus formed at lower angle, but after a few days the wound closed again. Twenty-five days have passed since operation.

The normal movement of foot has returned, and for ten days the patient has been walking about with a cane, complaining only that the limb is weak from long disuse. No apparatus is necessary, as the power of the flexor muscles is sufficient to counteract the extensors. The questions arise—

Will this nerve regain its function? If it does, will the pain return, or will the rest given by the suspension of its functions cure the local inflammation?

If the function never returns, what will be the result? Simply a loss of motion and sensation in some small muscles of the foot, having little connection with locomotion, and their final degeneration by fat.

Louisville, Ky.

IODINE AN ANTIDOTE FOR SNAKE-BITE.

By GEORGE H. CARPENTER. M.D.,
of Moorefield, Hardy Co., West Virginia.

Eight or ten years ago, I read an account of a case of snake-bite (in that case the rattlesnake) having been treated and speedily cured by iodine applied locally, and *administered internally*.

I am now unable to find the report, nor can I remember the journal in which it appeared, but the result of the treatment was such as to cause me to hold it in remembrance, to be used in case an opportunity presented. Up to this time I have not met with a case bitten by the genus *Crotalus;* but two cases bitten by the copperhead have fallen under my care, which I think clearly illustrate the potency of the remedy.

Case I.—A. W., male, aged thirty, of robust constitution; lives on the mountain, twelve miles distant from this place. In August, 1881, about two o'clock at night, he arose from bed, and in walking across the floor in his bare feet was struck on the instep of both feet by a copperhead snake, which was soon found and killed. Sharp pain was at once felt at the points of lesion, and the swelling of both feet was very rapid. I saw him at 7 A.M., five hours after the encounter. He had taken a quantity of whiskey, and had both feet and legs enveloped in poultices made of raw onions reduced to a pulp. His suffering was terrible. Countenance palid and anxious; breathing labored; pulse vacillating; had vomited repeatedly, and there were muscular twitchings throughout the entire body. I immediately gave him gtt. xv of the tinct. iodin. comp., in a third of a glass of water. I then had the poultices removed, and found both extremities mottled and swollen to the knees. After painting them with iodine, the poultices were restored. In about a half hour the intensity of the paroxysms of pain began to lessen, and at the same time there was a corresponding improvement in all the other constitutional symptoms; and in one hour from the time I administered a single dose of the remedy, I left my patient comfortable and cheerful. I directed the local application and a dose of ten drops of the tincture to be repeated every three hours for several days.

In about two weeks this man came to my office and informed me that the pain never returned; that in a few days the swelling began to subside, and he was soon on his feet. There remained some local tenderness and a sense of stiffness in the feet, but this gradually disappeared, and he has since experienced no ill-effects of the bite.

Case II.—B. E., living on the same mountain, was bitten on the dorsum of the hand by a copperhead snake in the latter part of June, 1882. I could not see this patient, but his condition, as described by the messenger, was similar to Case I. I sent him a vial of tinct. iodin. comp., and directed it to be used the same as above described. I have since met this man, and he reports a like happy result of the treatment, except that the local swelling and tenderness continued for several months; but at this writing the appearance and usefulness of the member are fully restored.

The copperhead snake, in considerable numbers, inhabits the mountains and marshes of this section; and I can cite a dozen or more persons in this immediate neighborhood who have fallen victims to his venomous bite, and who carry disabled members after enduring intense and prolonged suffering. Perhaps the majority of these cases were not treated by a physician; but it would be safe to say that all of them had the trial of whiskey and the onion poultice, that being the popular domestic plan.

Comparing these cases with the two I have reported, I think it may justly be claimed that the internal use of iodine exercised a potent influence on the latter. In my limited opportunities for examining the literature of the subject, I have not, except in a single case, seen the *internal* use of iodine recommended for the bite of venomous serpents and insects. The relief it afforded in the two cases in which it was prescribed by me was so marked and gratifying, that I must bespeak for it a reasonable trial in similar cases.

MEDICAL PROGRESS.

Character and Nature of the Processes Resulting from Inoculation of Peripneumonia.—M. G. Colin, in a memoir to the *Academié des Sciences*, gives the following as the outcome of his experiments on the subject:

1. The inoculation of virus from peripneumonia of cattle results in the development, in the cellular elements underlying the skin, or in those of the muscular interstices, of a process which is, from a pathological and histological point of view, the equivalent of that of the lung and pleuræ in contagious peripneumonia. This process is characterized by fibrino-albuminous exudations, yellow, charged with leucocytes, with nuclear epithelium, granules of various kinds, the exudations being similar to those produced in the interlobular connective cells of the lung.

2. The exudation furnished by the irritated connective tissue after inoculation produces, by its liquid and solid parts, a virulence equal to that of products of the same nature formed in the lung tissue of animals affected with peripneumonia.

3. Inoculation by the ordinary procedures does not

seem to confer immunity, as it is followed by a reaction transferred by a more or less prolonged tumefaction, œdema, and exudations in a cellular region.—*Gaz. Hebdom.*, March 30, 1883.

CHROMIC ACID IN AFFECTIONS OF THE TONGUE.—MR. HENRY T. BUTLIN, F.R.C.S., has used chromic acid in certain affections of the tongue, with markedly good effect. In June, 1881, he treated two cases of glossitis with a ten grain solution of chromic acid in water, painted on the sore areas of the tongue three or four times a day. Both cases improved. A case of secondary syphilitic, deep and jagged ulcers of the tongue, and ulceration of the inside of the cheek, which showed no improvement under hyd. c. cret., iodide of potass., or liq. hyd. bichlor., were, after a week's treatment with chromic acid solution, almost completely healed. Another case of flat mucous tubercles, due to secondary syphilis on the right border of the tongue, which had resisted treatment with hyd. c. creta for about three and a half months, was almost completely cured in three weeks.

Mr. Butlin has used chromic acid in several different inflammatory conditions of the tongue, in many cases with most gratifying success. In 27 cases, 20 have been cured or greatly relieved, 7 having received little or no benefit. The seven cases were either of chronic superficial glossitis, or of *tertiary* syphilis. The twenty include seven of chronic superficial glossitis and thirteen of various *secondary* syphilitic affections. Mr. B. concludes that chromic acid cures with marvellous rapidity *secondary* affections, ulcers, mucous tubercles, and condylomata. It produces no appreciable effect on *tertiary* affections, gummata, extensive ulcers, or tubercular syphilides. Some cases of chronic superficial glossitis, with slight ulceration and renewed inflammation are rapidly benefited by it. In cases of glossitis in which the tongue surface is attacked by a fresh inflammation of great severity, glycerite of boracic acid and soothing remedies are more suitable; chromic acid rendering these worse. He reports one case of *tertiary* syphilitic ulcers of the tongue which was cured in about two months by combined chromic acid and mercury treatment, although it had obstinately resisted purely anti-syphilitic treatment for many months. The strength of the solution usually employed is grs. x–℥j water; in some cases grs. xv–℥j. The patient is told to paint the diseased parts three or four times a day with a camel's-hair brush dipped in the solution. There is seldom any pain or discomfort; sometimes a little smarting at first.—*Practitioner*, March, 1883.

DOUBLE HYDRONEPHROSIS WITH DILATATION OF THE BLADDER AND URETERS DUE TO DISEASE OF THE PROSTATE.—PROF. D. WEBSTER PRENTISS read a report of this interesting case before the Medical Society of the District of Columbia, January 24, 1883, of which we make the following abstract: Thomas H., æt. 58, printer. Health good previous to present disease, which began two years ago. The first symptoms were difficulty in urinating, retention of urine, irritability of the bladder, with phenomena of vesical tenesmus, which were soon followed by incontinence and constant dribbling of urine. No constitutional disturbance up to three months ago, when uræmic symptoms began to develop. The appetite, strength, and nutrition were unimpaired. He had been under treatment by various physicians, who prescribed tonics, diuretics, and lately full doses of ergot, for a supposed diabetes mellitus. Dr. Prentiss first saw the patient on December 17, 1882, at which time he was evidently suffering from uræmia; had been having violent headache in the morning for three months. For five weeks there had been progressive anorexia, weakness and emaciation, and nausea and vomiting for four weeks, which symptoms were very marked at the time of the first visit. The most distressing symptom at this time was dyspnœa, which had developed one week before, apparently due to pulmonary emphysema. No cough or other lung disease. No evidence of heart disease; *no dropsy*.

The amount of urine passed, making allowance for that lost by dribbling, was about two pints in twenty-four hours. It was offensive, alkaline, sp. gr. 1005; no albumen.

From the general symptoms Bright's disease was diagnosticated. Ordered hot baths and pilocarpine, tonics, stimulants, and milk. No relief. Microscopical examination of the urine, by Dr. Schæffer, showed no indications of bladder or kidney disease. Patient grew worse and died on December 27, 1882.

Autopsy, December 28th. Bladder appeared as a whitish, fibrous-looking, irregularly nodulated tumor, reaching nearly to the umbilicus, and distended with urine of the same character as that examined during life. The kidneys, bladder, and uterus were removed for further examination. After maceration in alcohol the bladder measured seven inches in length and four inches in transverse diameter; walls greatly thickened and rough, traversed by a coarse network of fleshy cords resembling the columnæ cornæ of the heart. In many places between these bands were pouch-like dilatations, which gave to the external surface of the bladder a nodulated appearance. There was no obstruction to the outlet of the uterus, and no apparent dilatation of them near the bladder. The most important pathological condition found was the *peculiar enlargement of the middle lobe of the prostate, which projects into the neck of the bladder in such a manner as to form a valvular obstruction to the escape of urine.*

Each ureter was twelve inches long, dilated irregularly from the size of a pencil to that of the thumb, the largest size being at their departure from the pelvis of the kidney. The kidneys (pelvis?) were both dilated to a capacity of about one-half pint, and contained that amount of urine. The kidney structure proper was reduced in thickness to about one-third or two-thirds of an inch. The early use of the catheter would undoubtedly have prevented the development of hydronephrosis.—*Maryland Med. Journal*, April 1, 1883.

SUBMUCOUS INJECTIONS OF CHLOROFORM. — For about six years, M. GUILLOT has been using injections of chloroform into the submucous tissue of the gums for acute odontalgia. Used in this manner, it acts more quickly than injections of morphine. In a series of 100 cases treated in this manner by Dr. Dop, 79 were appreciably benefited. He introduces the needle parallel to the line of the jaw to the depth of about one inch, taking care to keep it close to the bone. By this means there is little or no loss of the liquid when the needle is withdrawn. He has never had consecutive inflammations or ulcerations after this treatment. He has used chloroform not only by injection in cases of odontalgia with pulpar hyperæsthesia, but also as a lotion to allay the pains after extraction of teeth; gtt. v–vj, in a glass of warm water. This lotion will sometimes arrest the hemorrhage after extraction. — *Le Progrès Méd.*, March 24, 1883.

AN INSECT GENERATING PRUSSIC ACID.—In many of the houses in Holland, there is found a myriapod, genus *Fontaria*, which enjoys the singular property of exhaling a strong odor of prussic acid when excited. According to M. EGELING, the insect secretes a substance, which under certain conditions is decomposed into several products, notably into prussic acid. An American myriapod, the *Fontaria Virginica*, also exhales a slight odor of this acid.—*Revue Scien.*, March 31, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.

SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, APRIL 21, 1883.

KOCH AND HIS CONTINENTAL CRITICS.

IN our last issue we considered the criticisms against Koch's new doctrines as found in American literature. Of the German, Koch says, that he who supposes that it has produced no such fruit as that just adduced, will be mistaken.

Beneke seems to have made a mistake similar to that of Schmidt, having obtained bodies which he mistook for bacilli, from alcoholic and ethereal extracts of normal blood.

The assertion of Cramer, that he had found in the alvine dejecta of twenty healthy persons, bacteria which, on treatment by Ehrlich's method, responded to the color-reaction of tubercle-bacilli, Koch considers overthrown by the counter-results of Menche and Gaffky, who failed to find anything corresponding in reaction to tubercle-bacilli in the evacuations of healthy persons. Menche ascribes Cramer's results to deficient decolorization of the bacilli.

The somewhat similar results of Balogh, who claims to have found, in mud, bacilli similar to tubercle-bacilli, Koch claims to have himself refuted. He treated mud very rich in bacteria, according to Ehrlich's method, but discovered none reacting like the bacillus tuberculosis.

And here Koch makes the important announcement, that even should there be found in the intestinal canal, bacilli which possess the same reaction as tubercle-bacilli, and of the same size and form, this does not alter the state of the case. It is the pathogenetic property which is important, and if this is wanting, an identity of form and reaction goes for nothing. He further calls attention to the fact that he never asserted that bacteria do not exist which give the same color-reaction as the tubercle-bacillus. He quotes his own language from the original paper as follows: "All other bacteria as yet investigated by me, except the lepra-bacilli, take, with this method of staining a brown color." He has not, however, in his subsequent experience met other bacteria than these two, which respond in like manner.

With regard to inhalation experiments, those of Balogh, as well as the more extensive ones of Schottelius, according to Koch, go for naught. That the lungs react by the formation of nodular particles when foreign bodies like animal parasites, actinomyces, and even lifeless particles are inhaled, has long been known. But these nodular bodies, he says, are not true tubercles. And it goes for naught that their histology is identical with that of true tubercle. Such nodules are no more tubercular, according to Koch, than the pustule produced by tartar emetic on the skin is the same thing as the pustule of variola, although they are anatomically the same. Koch charges Schottelius with discarding all evidence of the parasitic nature of tubercle. The tubercle-bacilli are for him only accidental accompaniments of the disease, whereby Schottelius forgets that the evidence as to the etiology of tuberculosis is the same as that for anthrax. If he denies the significance of the tubercle-bacillus, he must also deny that of the bacillus of anthrax. Indeed, if he is consistent, he must also regard trichina and itch insects as accidental concomitants, and not as causes of the diseases they attend.

On the other hand, Koch will have no criterion of tuberculosis except the etiological one. Of course, if there be no anatomy for tubercle—and that is only considered tubercle which is the result of inoculation with tubercle-bacilli—there is no arguing the question, and the matter ends here. For if there is no anatomical criterion for tubercle, how are we to know what is tubercle, and what is not? The answer may be, by the presence of the tubercle-bacillus. But this, again, is begging the question. There is no doubt in our mind that the anatomical characters, which, with a considerable degree of constancy, have been shown to be associated with tubercle, are sufficient in the majority of instances, when present, to enable us to say of a given morbid product, it is tubercular, and the result of the condition known as tuberculosis.

Koch contends for the identity of tuberculosis in man and the "Perlsucht" of cattle, and holds that the facts adduced by Bollinger and Schottelius as to the harmless consumption by man of flesh from animals thus infected in no way disproves such identity. For, in the first place, it is not known

whether the persons consuming this meat actually ate such as contained tubercle-bacilli, which are mostly found in parts likely to be thrown away, or worked up in such way by the butchers as to be sold or exchanged among persons lost sight of. Again, even if flesh containing bacilli is consumed as food, it does not follow that the consumer must in every instance become affected with tuberculosis, any more than consumption of the flesh of animals suffering with anthrax should be invariably followed by this disease, many cases of such exemption having fallen under Koch's notice. We think the impartial observer must here agree with Koch.

The conclusions of Schottelius, from differences in the structure of the smallest bronchi of herbivora and carnivora, as the result of which he concludes that the former are more susceptible to tuberculosis than the latter, Koch says, are overthrown by the fact that the cat, which is carnivorous, may be easily infected, while certain rodents, as mice and rats, are infected with difficulty.

As to Dettwiler, who adopts completely the conclusions of Schottelius, and who holds that the inoculation-results with tubercle-bacilli show nothing, because in animals only miliary tuberculosis is produced, and not the typical phenomena of phthisis, Koch refers him to the experiments upon the origin of miliary tuberculosis by Weigert, who has shown that other infectious diseases pursue in animals a course different from that observed in man, as especially illustrated by anthrax. A rabbit or Guinea-pig inoculated from the carbuncle of anthrax in man does not acquire a carbuncle, but general infection. We nevertheless use rabbits and Guinea-pigs for the etiological study of anthrax, and the results are allowed, even though the typical course of the disease in the animal, whence the inoculating material is derived, is not followed.

He concludes with his demolition argument, that Dettweiler knows nothing about bacteria-studies, and asks the question: Why, if bacteria are but the accidental attendants of disease, do we have this form of bacillus in every situation and variety of tuberculosis, another large bacillus in anthrax, micrococci in erysipelas, the spirochæta in relapsing fever? etc. Finally, he asks Dettweiler why he requires his phthisical patients to spit into a solution of corrosive sublimate, and concludes that he allows himself to be influenced too much in his bacteria investigations by his position as the conductor of a sanitarium.

But it is for Spina that Koch reserves his severest criticism. He says that the appearance of Spina's paper was so loudly and boastfully proclaimed, that he had reason to expect a carefully elaborated work which would in some way, at least, enrich science, especially as Spina was the first to undertake to test his investigations in their entirety; but he has seldom seen a more miserable production than this very work of Spina's. He then criticises Spina's methods: that he uses a water-immersion objective, instead of an oil-immersion with Abbe's illuminator; he uses his color solutions and other reagents erroneously; he investigates his aniline-stained preparations in glycerine instead of Canada balsam; he uses as a medium for demonstrating a special class of bacteria, a substance containing bacteria, namely, saliva. Spina's microscopic technique is the very opposite of what it should be for the investigation of bacteria. With these methods failure is inevitable, and Koch doubts very much whether Spina ever saw a tubercle-bacillus, and considers that all conclusions which Spina has reached in his microscopic investigations upon tuberculosis are worthless.

As to Spina's attempts at culture of the tubercle-bacillus and inoculations therefrom, experiments always attended with greater difficulty than the simple demonstration of the tubercle-bacilli themselves, they can only be considered as caricatures of Koch's own experiments. All the conditions and requirements of proper and successful cultures have been disregarded by Spina. Notwithstanding this, he attempted to inoculate with the products thus obtained. *Two* rabbits were inoculated with the dry bacteria crusts which Spina had cultivated upon his serum-gelatine, one of which died in eighty-six days with tuberculosis of the lungs—"inhalation-tuberculosis," says Koch—the other in forty-three days, with healthy lungs, white nodules in the diaphragm and spleen, but with no other of the phenomena which, in the rabbit, so strikingly characterize inoculation-tuberculosis. What a contrast, says Koch, to his own experiments, in which *several hundred* animals of different species were inoculated, not subcutaneously only, but also in the peritoneum, anterior chamber of the eye, etc. Each experiment was made upon three, four, and often ten animals, while control-experiments were made upon one or two animals. The animals were not allowed to live eighty-six days, but were killed at the end of four weeks at the outside, for the reason that rabbits especially, if inoculated with indifferent substances, become tuberculous if they are kept long enough in infected enclosures, and Koch places great stress upon the distinction between inoculation-tuberculosis and spontaneous tuberculosis.

Koch's summarized estimate of Spina's work is expressed in the following extract: "All things taken together, it is evident from the foregoing, that Spina understands neither how to study bacteria microscopically, how to cultivate, nor how to inoculate them. Upon the study and significance

of tubercle-bacilli his work can have no influence. Its only consequence is that Spina has greatly injured his own scientific position and that of the institute in which he acquired his knowledge of bacteria, and under whose authority he has published his work. If he does not wish this blot to be permanent, the only thing which remains to him, is to begin his bacteria-studies anew, to acquire the necessary preliminary knowledge and experience in easier tasks, and finally, upon the ground of a thorough experimental work upon tuberculosis, openly and honorably acknowledge his errors."

In concluding his critical discussion, Koch again calls attention to the fact that the only research which attempted to test his work in all its aspects is that of Spina, which terminated thus most unfortunately. None of the remaining criticisms contained anything which in the least degree shakes his conclusions upon the etiology of tuberculosis. The task has not been a pleasant one to criticise so thoroughly a worthless literature, but he could not, from his interest in the matter, escape the duty, and hopes still to meet more carefully prepared material.

We have thus, at greater length than may at first thought seem justifiable, presented the reply of Koch to his critics. But the subject is a most important one, and we wish to place before our readers, as far as possible, the facts on which they may base their own conclusions, simply calling attention to points in which Koch has either the advantage of his critics, or himself claims more than is just and reasonable. We cannot but think the impartial reader must conclude that Koch is rather too dogmatic and self-asserting, and speaks with rather more than the amount of confidence which characterizes a properly balanced scientific mind, whose only object is to establish the truth, and not an opinion or theory of his own. On the other hand, it must be admitted that none of the critics have repeated his experiments with the care and exhaustiveness which he has used. And we sincerely hope that some one properly skilled in microscopic technique will repeat them with all the patient care and accuracy which the subject demands. It must be remembered that in order to prove tuberculosis to be an infectious disease, two points must be established: 1st. That tuberculosis cannot be produced by the inoculation of what are commonly spoken of as indifferent substances; and, 2d. That the cultivated bacilli, the inoculation of which is acknowledged by all to produce tuberculosis, are pure, and unmixed with any other matter.

MIGRAINE AND ORGANIC CEREBRAL DISEASES.

Persistent attacks of migraine, there is reason to believe, have a rather close relation to the development of cerebral mischief. Many of those who experience such attacks, have a neurotic disposition, and years after their onset suffer from more or less serious affections of the nervous centres. Such is the common experience. New light has been thrown on this interesting subject by M. Ch. Féré, in two papers, which have recently appeared in the *Revue de Médecine*. Féré holds that a pathogenetic relation exists between the ophthalmic form of migraine, especially, and certain cerebral disorders. There is, as is well known, an epileptiform variety of neuralgia affecting the ophthalmic division of the fifth nerve. Charcot has observed cases of dementia paralytica preceded by attacks of migraine. Parinaud has also published a paper on attacks of ophthalmic migraine, which usher in general paralysis. Féré reports a case recently observed with Charcot, in which attacks of sick-headache beginning at puberty, continued through many years, and were followed by aphasia, hemiplegia, convulsions, cerebral hemorrhage, and death. In this case there was no history of hereditary neuroses, nor did the patient present any other evidence than this affection, of a neuropathic tendency.

The peculiarity of the migraine consisted in the visual disorders, which sometimes preceded by twenty-four hours the pain in the head. These disturbances of vision consisted in a rapid, tremulous movement of external objects, colored rings, zigzag lines sometimes of light—sometimes of shadow, and occasionally there was simple obscuration of vision, for one-half or the whole of the field. Again it happened, that the images of objects remained long on the retina, or a black point appeared on the page and persisted for a half-hour at a time. The visual disorders usually disappeared as the headache came on, but sometimes persisted throughout the seizure. The termination of the attack was usually by vomiting, much bilious matter being brought up.

A symmetrical and bilateral organic lesion of the brain resulted after many years. Féré explained the occurrence of these lesions by a dynamical agency. "In migraine," he says, "there occurs a temporary contraction of the vessels, under the influence of some vaso-motor disorder. After a time, this contraction becomes permanent, and an almost complete closure of the vessels results, and this determines a thrombosis, from which ensues the death of the tissues comprised in the vascular territory attacked."

If ophthalmic migraine persisting through many years results so disastrously, as we have reason to believe is the case in some instances at least, does not this malady assume a higher position, both from the diagnostic and therapeutic points of view?

TRIGEMINAL NEURALGIA.

THAT *bête noir* of the inexact orthographer and of the surgeon—*tic douloureux*—is the subject of an extremely interesting article by DR. F. H. GROSS in the April number of the AMERICAN JOURNAL OF THE MEDICAL SCIENCES, and is worthy of more than a mere passing notice, by reason of the thus far successful surgical measures adopted.

No one of the three branches of the fifth nerve was exempt from pain of the typical, atrocious character. After the futile employment of medical means, Dr. Gross found that compression of the carotid relieved the pain, and, acting on the hint, he ligated the common carotid artery. Following the proposal of Nüssbaum, this artery has been ligated for prosopalgia fifty-four times, and it is extremely interesting to note the difference in the mortality after ligation for this disorder when the patient is in good bodily health—saving the pain—and its ligation for other disorders when there is actual disease. Hueter gives the mortality after the 54 ligations of the carotid for prosopalgia as 3; *i.e.*, only 5 per cent. In 600 miscellaneous cases of carotid deligation collected by Pilz, in 1868, deducting 22 of unknown result, the mortality was 43 per cent.

The proposal of Dr. Roberts, in the discussion which followed, in the Philadelphia Academy of Surgery upon Dr. Gross' case, to tie the internal carotid, we do not regard as a happy one, since the operation is more difficult and less reliable than that of the common trunk, and the chief danger—insufficient nourishment of the brain—is not lessened. The relief to the pain in the first division of the nerve has thus far been permanent, after nearly three years. But after two years it returned in the second division. In the third division, the relief was almost *nil*. Eight months later, the inferior dental nerve was resected, and relief obtained for fifteen months. Last fall the superior maxillary was exsected, and a similar operation was done a second time on the inferior dental after two months. Thus far the relief is satisfactory.

We say "thus far," because it is not only possible, but we fear probable, that the disease will return. But granting that it does, has not the relief been a boon well worth the risk?

DIVULSION OF THE PYLORUS.

IN another column we present an account of an important new abdominal operation—divulsion of the pylorus—which deserves careful reading.

Of course the merits of the operation cannot be decided by four cases, but *primâ facie* it looks well. The operative procedure is simple, and not too prolonged; it involves not too great a risk in view of the gravity of the disease for which it is done; its statistics so far are reasonably good, especially in view of want of experience as to its dangers and their avoidance. The chief difficulty, we opine, is in the diagnosis. The disease—non-malignant stenosis of the pylorus—is certainly rare in this country and in Great Britain, but minute and careful physical and clinical examinations may, with fair certainty, discover the nature of the lesion.

Dr. Harris' suggestion as to previous rectal alimentation is certainly a wise one. It might readily turn the scale between life and death, and ought never to be forgotten; moreover we see no reason why the divulsion should be restricted to the fingers. While generally the best, it may be found that instrumental divulsion, in some cases, may be preferable.

The abdomen—until recently the *terra incognita* of surgery—has yielded many triumphs to modern genius and skill. What will be the next one?

DEATH OF JOHN BROWN.

THE last issue of the *Lancet* received in this country gives the particulars concerning the death of John Brown, the Queen's personal attendant. *Pallida mors æquo pede pulsat pauperum tabernas regumque turres.* He had an attack of erysipelas of the head, induced by exposure to cold, and notwithstanding the solicitude of his royal mistress, and the skilful management of Sir William Jenner, he succumbed after an illness of three days. We are not so much concerned, as are our English contemporaries, over the loss sustained by the Queen in the death of her faithful body-servant, but we have a professional interest in the manner of his taking-off.

The erysipelas appeared on the nose and cheek, and thence rapidly extended over the head. On the second day, the fever was very high, and delirium came on; on the third day he became comatose, and died. It requires but a superficial survey of such a case to indicate the points in which it differs from ordinary erysipelas of the face. Not more nearly does an ordinary boil resemble the malignant carbuncle which has its seat on the upper lip and nose. It was Dr. Bastian, of London, we believe, who first found minute embolisms of the brain in cases of erysipelas of this kind. The vascular communication between the facial vein, the pterygoid plexus, and the cavernous sinus is the medium by which emboli formed in the facial vein reach the intra-cranial vessels. It may be asked—As this vascular communication exists in all persons, why does not the same result follow in every case of facial erysipelas? That it does not, signifies that there is some difference in the nature of the

two varieties. A poison is generated by the local morbid process in the one that is not produced in the other, or some unknown condition of the system precedes the local manifestation.

The medical profession feels a just pride that the genius of one of its members has marked an era in the English literature of our century, and, therefore, on the occasion of Dr. Holmes' retirement from active medical teaching, the banquet which was given in his honor last week in New York as an expression of this sentiment by the profession, was a fitting tribute happily conceived, and gracefully executed.

The poem which Dr. Holmes wrote for the occasion, and which is printed in another column with the account of the banquet, shows that though while in the evening of life he seeks to lighten his burthen, it is not because his mind has lost any of its vigor; and that in his abandonment of medicine the poet will have greater opportunities to reap fresh laurels in literature.

"The true knight of learning, the world holds him dear,
Love bless him, joy crown him, God speed his career."

SOCIETY PROCEEDINGS.

THE KENTUCKY STATE MEDICAL SOCIETY.

Twenty-eighth Annual Session, held in Louisville, April 4, 5, and 6, 1883.

Wednesday, April 4th, the Society met in annual session at Louisville, at 12 M., with the *President*, Dr. A. D. Price, of Harrodsburg, in the chair.

Dr. Coleman Rogers, of Louisville, as *Chairman of the Committee of Arrangements and Credentials*, welcomed the Society to the city in a cordial address.

The report of the *Treasurer*, Dr. Edward Alcorn, of Hustonville, was presented by the Secretary, and, on motion, was approved.

The *Secretary*, Dr. L. S. McMurtry, of Louisville, made his annual report. Letters were read from Prof. S. D. Gross, M.D., and Dr. J. J. Woodward, both honorary members of the Society. The report of the Secretary dealt in detail with the correspondence and publications of the Society during the past year, and, on motion, was received and approved.

The Committee on Credentials reported, through its chairman, that the following *Applications for Membership* had been received and considered, and the gentlemen were recommended for membership: Dr. E. S. Moss, of Williamsburg; Dr. Ancil Gatliff, of Williamsburg; Dr. Walter Byrne, of Russellville; Dr. R. Maupin Ferguson, of Louisville; Dr. William C. Webb, of Bryantsville; Dr. T. D. Finck, of Louisville; Dr. W. A Jemison, of Eminence; Dr. J. A. Stucky, of Lexington; Dr. George Horine.

On ballot, the above applicants were elected to membership.

Dr. I. B. Greenley, of Jefferson County, made the report on the

PROGRESS OF MATERIA MEDICA AND THERAPEUTICS.

He referred to the extensive use being made of iodine and iodide of potash, as well as carbolic acid, in the treatment of typhoid and malarial fevers. His experience in the treatment of intermittents is favorable to the further trial of the sulphites and hyposulphites. Borax in epilepsy he recommends when the bromides fail. Atropine and ammonium bromide have likewise served, in his experience, as useful remedies in the treatment of spasmodic affections. The treatment of vomiting by the use of water as hot as it can be borne he refers to as an old treatment revived to subserve a useful purpose. The *Viburnum prunifolium* has maintained the reputation it acquired upon its advent into professional favor as applicable to threatened abortion. *Eucalyptus globulus* has failed to meet the expectation indulged by those who anticipated in its use a valuable substitute for the preparations of Peruvian bark. *Pinus Canadensis*, for chronic diarrhœa and inflammation of the urinary passages; Dugong oil, as a substitute for cod-liver oil; calcium chloride, in granular enlargements, have each been productive of good results in the author's hands.

Dr. J. W. Holland called attention to the unreliability of manufactured preparations of the standard medicines, and particularly the unreliability as to quantity in quinine pills said to contain one, two, and three grains each. The speaker claimed to have knowledge that justified the statement that such were almost invariably of short weight, no matter by what manufacturer made. In many instances pills marked two grains contained but a fraction over one, and others varied accordingly. The purity of the alkaloid in many could not be warranted, not even commended. He referred to an analysis, which is to appear shortly in the medical press of Louisville, on which these statements are founded, this analysis having comprehended pills made by various establishments, not one of which is to be designated in the report.

Dr. W. M. Fuqua, of Hopkinsville, as chairman of the committee, delivered the

REPORT ON SURGERY.

Wound treatment first engaged the speaker's attention. Under this head reference was made to antisepsis as practised by applications, such as carbolic acid and iodoform. The speaker deprecated the almost universal use of iodoform for the reason that absorption of the drug has been followed by unpleasant mental symptoms showing the poisonous effect of the drug when absorbed. Drainage received fit consideration in this connection. The field of micro-organisms was hastily scanned, and the lessons of the first discoveries in the field applied to to those of later dates, and the influence upon future investigations foreshadowed. The germ theory, as applied to typhoid, malarial, and scarlet fever, found in the author a firm believer and forcible exponent. "Peritoneal surgery," the speaker said, "has grown with the growth of the antiseptic system. In the treatment of wounds involving the peritoneal cavity, Sims expresses the most recent utterance when he declares that unfavorable terminations are the result of septicæmia and not peritonitis, and that this septicæmia is due to effusions into the peritoneal cavity. Resection of the pyloric extremity of the stomach has been performed perhaps fifteen times. Three thus operated upon are still alive. The probabilities are that the operation will never be recognized as a justifiable procedure. Operative procedures for the relief of intestinal obstruction, colotomy; rupture and gunshot wounds of the bladder; hernia, and operations upon the chest and lungs were each in turn considered. In gynecology the greatest advances have been made by native talent. Operative measures for the relief of epilepsy, as recently shown by Dr. Alexander, are likely to be productive of benefit, and will shortly, in the estimation of the speaker, prove of recognized utility. Shock, that peculiar and often fatal

condition incident to grave surgical operations and injuries, was not clearly understood until of late years. Light has been shed upon the subject by recent investigations which indicate that the condition is one of paralysis of the abdominal vessels and nerves, for the relief of which alcohol, ammonia, and especially ether and atropia are most efficient.

Discussion of this paper was confined to a consideration of the subject of antiseptics, and particularly the dangers attendant upon the use of iodoform.

DR. J. M. MATHEWS, of Louisville, said that he had freely used iodoform as an antiseptic for a number of years; and without once having reason to suspect that by its application he had done the patient harm. In treating diseases of the rectum he has used it freely, packing an ulceration with it as many as three or four times a week, and continuing this for three or four weeks, until a healthy action had been excited. He has yet to meet a single case wherein any deleterious or dangerous symptoms followed as a consequence of its use. As to its local effect, he thinks no surgeon can have a doubt as to its excellence.

DR. D. W. YANDELL, of Louisville, remarked that what had been said touching the dangers of iodoform does not apply to its application to the small surface to which it must be applied in cases of affections of the rectum, but to the absorption of the substance when used in enormous quantities. He wished to confirm in his own experience the value of iodoform in rectal troubles. He had found it of especial use in the treatment of hemorrhoids after operation for removal by any of the usual methods. In some cases there is a good deal of active inflammation left, in others a sluggish condition of the parts, a callous-edged ulcer, or much infiltration in the adjacent tissues. Under these circumstances, but more particularly in the acute ulceration that follows, he has almost invariably gotten good results from iodoform. He quite concurs in the remarks of Dr. Mathews touching its harmlessness.

DR. D. S. REYNOLDS, of Louisville, while quite agreeing with the gentlemen with reference to the importance of the use of antiseptics, recognizes a great difficulty in the want of a selection of the proper kinds of antiseptics for particular conditions. Thus, the chloride of sodium is an efficient antiseptic in acute purulent inflammations of the mucous membranes, while boracic acid is applied with better results to those of a chronic form. Thymol and eucalyptol are of like benefit in the treatment of those inflammations which become septic by becoming purulent, as in the cavity of the middle ear, the tear passages, and other similar conditions. The *Aspergillus albicans*, which invades the external ear, is destroyed perhaps more readily by eucalyptol and thymol than by other agents, though boracic acid is not to be neglected in fungoid growths of this character. The *Tinea tonsurans*, which invades the hair follicles, is quickly destroyed by boracic acid. When we are able to classify the germs we shall then be able to arrive at some definite conclusion as to the selection of the germicide applicable.

THURSDAY MORNING, APRIL 5TH.

DR. TURNER ANDERSON, of Louisville, Chairman of the

COMMITTEE ON NOMINATIONS.

made the following report from that Committee:

President.—DR. J. N. MCCORMACK, of Bowling Green.

Vice-Presidents.—DRS. J. M. RIFFE, of Covington, and J. M. HARWOOD, of Shelbyville.

Secretary.—DR. S. M. LETCHER, of Richmond.

Assistant Secretary.—DR. J. S. MOORE, of Lebanon.

Treasurer.—DR. H. BROWN, of Hustonville.

Librarian.—DR. A. M. VANCE, of Louisville.

Bowling Green was recommended as the *next place of meeting.*

On motion, the report of the committee was unanimously adopted.

DR. ANDERSON then read the following resolutions, which the Committee on Nominations recommended for adoption by the Society:

Resolved, That the Kentucky State Medical Society receives with regret the resignation of Dr. L. S. McMurtry as permanent secretary.

Resolved, That the thanks of the Society be accorded Dr. McMurtry for the able and faithful manner in which he has discharged his duties, and for his untiring devotion to the interests of the Society.

On motion, the above resolutions were unanimously adopted.

The following *Committee of Arrangements and Credentials* was appointed for the next session: T. J. Townsend, chairman, Bowling Green; W. E. Hatcher, Bowling Green; J. F. McElroy, Bowling Green; Walter Byrne, Logan County; J. P. Thomas, Christian County.

DR. PRESTON B. SCOTT, of Louisville, read a paper on the subject of *Disorders of the Menstrual Function.*

DR. J. N. MCCORMACK, of Bowling Green, read a paper on *Hygiene*, which was for the most part devoted to a consideration of the duties and powers of boards of health, comparing the State Board of Health of Kentucky with the boards of other States. He discussed the duties and powers of local and county boards in relation to State boards.

DR. J. A. LARRABEE, of Louisville, in discussing this paper, said the greatest obstacle to the successful control and prevention of disease is the lack of knowledge and interest on the part of the people on the subject. In addition he called attention to the fact that here in this city, where we might reasonably expect the exhibition of attention on the part of our health authorities, during last fall in one neighborhood there was an epidemic of typhoid fever, during which he saw forty-five cases. All cases were distinctly traceable to one well used for drinking-water, and the well has never received any attention in the way of cleansing, but remains open for use and for the spread of disease.

DR. THOS. F. RUMBOLD, of St. Louis, by invitation, read a paper on the *Treatment of Chronic Naso-pharyngeal Catarrh.*

DR. W. O. ROBERTS, of Louisville, reported several *Cases of Head Injuries* in which operative procedures had been rendered necessary.

TREPHINING IN EPILEPSY.

DR. D. W. YANDELL exhibited the skull of a woman who was operated upon by Dr. Gross, in 1854. In 1867 she began to have epileptic convulsions, which continued to occur till her death, in 1872. Over the opening made by the trephine in this skull, a fibrous membrane of considerable strength had grown. Just inside an excrescence the size of a pea was formed. From the irritation caused by this it is supposed epileptic manifestations arose. Another case of which he spoke was of a man shot, during the war, in the frontal region, and who, apparently fully recovered, was seized with epileptoid convulsions. In 1867 Dr. John O'Reily, since deceased, operated upon him, removing quite a small portion of bone. He made a good recovery, and is alive to this day.

A youth, kicked by a horse, near the centre of the frontal bone had a fracture, slightly depressed, but recovery took place without interference. In about two years he began to have epileptiform convulsions, and his temper underwent a change. Dr. Yandell applied the trephine, his epilepsy disappeared, his viciousness passed away, and he is now a useful citizen.

Dr. McCormack, of Bowling Green, reported a case which was brought to his office a little more than a year ago to be examined, in order that he might testify as to his sanity. He was twenty-three years of age. Six years before he was struck on the head with a sharp-pointed hammer, at which time he fell unconscious, and remained so for some time, but gradually recovered without any symptoms of trouble. He married at nineteen. He continued to all appearances well, until about six months before he consulted him, when he began to complain of great pain in the region of the former wound. He underwent some degree of emaciation. There was distinct depression at this point, though the excessive tenderness there prevented entirely satisfactory examination. Dr. McCormack removed a fairly large section, and afterward another section, and then rasped the edges. He recovered without a bad symptom. The remarkable feature in his case now developed itself. Shortly after he recovered he said he had no recollection of anything that had occurred from the day he was struck on the head until the day he was operated upon. Every precaution was taken to prevent any imposition, but he appeared to show no disposition to deceive. When he first became conscious, after the removal of the bone, his impression was that a short time before he had been struck on the head. He had no recollection of his marriage. He had bought a small farm and partially paid for it, but he would not believe it until he had examined the records for himself. He appears now to be in perfect health.

Dr. Frank C. Wilson, of Louisville, reported *Two Cases of Tracheotomy.*

Dr. Pinckney Thompson reported two cases of recovery from the operation, in each of which no tube had been used. Other cases in which it had been used had resulted unsuccessfully. He regarded the tube as harmful rather than efficacious, looking upon it as a foreign body in a delicate situation, and in itself sufficient to produce harmful irritation.

Dr. R. W. Dunlap, of Danville, spoke of two cases operated upon by the late Dr. John D. Jackson, both of which recovered. He used the tube in both cases.

Dr. D. W. Yandell reported a case in which the tube had been worn for a period of seven years.

Friday Morning, April 6th.

Dr. Seargent, of Hopkinsville, reported a case of *Strychnia Poisoning*, in which recovery occurred after the ingestion of twenty grains.

Dr. W. C. Webb, of Bryantsville, read a paper on *Pertussis and its Treatment.* He said that he considered croton-chloral, when properly administered, as a specific. The dose for a child one year old is one grain every four hours; from six to twelve, two grains; but adults can seldom stand more than four grains. It should be given regularly at stated intervals, both night and day; at the end of a week, only in the daytime.

Dr. J. A. Octerlony made a report on the *Progress of Dermatology.*

Dr. W. H. Wathen, of Louisville, exhibited to the Society a *Case of Hollow Needles*, which he had devised with special reference to the introduction of silver-wire sutures. The needles have different curves, adapting them to operations upon the perineum, vaginal walls, cervix uteri, and to staphylorrhaphy.

The President announced the Standing Committees, and the following

Delegates to American Medical Association.—Dr. D. S. Reynolds, Louisville; Dr. L. S. McMurtry, Louisville; Dr. J. A. Octerlony, Louisville; Dr. W. O. Roberts, Louisville; Dr. Geo. Bealer, Clinton; Dr. H. Brown, Hustonville; Dr. J. M. Riffe, Covington; Dr. L. P. Yandell, Louisville; Dr. J. P. Thomas, Pembroke; Dr. L. B. Todd, Lexington; Dr. W. H. Wathen, Louisville; Dr. J. N. McCormack, Bowling Green; Dr. T. B. Greenley, Jefferson county; Dr. Crawford, Bardstown; Dr. P. B. Scott, Louisville.

The Society then adjourned to meet in Bowling Green, on the first Wednesday in May, 1884.

[We are indebted to the courtesy of Dr. L. S. McMurtry, Editor of the *Louisville Medical News*, for advance sheets of that journal, from which our report has been collated.]

MEDICAL SOCIETY OF THE STATE OF TENNESSEE.

Fiftieth Annual Session, held at Nashville, April 10 and 11, 1883.

(Specially reported for The Medical News.)

The Tennessee State Medical Society met in its fiftieth annual session Tuesday, April 10, at 10 o'clock, in the Senate chamber at the capitol. The President, Dr. W. F. Glenn, called the Society to order, and Rev. J. P. Sprowls opened the exercises with prayer.

Dr. Deering J. Roberts, chairman of the Committee on Arrangements, delivered the address of welcome.

Gov. W. B. Bates was present by invitation, and appropriately welcomed the Society to Nashville and to the capitol.

The members of the Society registered

as present were G. A. Baxter, Vaulx Gibbs, Chattanooga; J. S. Nowlin, J. M. Coyle, W. F. Glenn, J. Berrien Lindsley, C. C. Fite, Deering J. Roberts, Paul F. Eve, W. P. Jones, George P. Williamson, J. E. Harris, W. M. Vertrees, James B. Stephens, Duncan Eve, J. R. Harwell, Orville H. Menees, Ambrose Morrison, J. F. Grant, Nashville; R. F. Evans, Thomas Lipscomb, Shelbyville; W. W. Taylor, Brownsville; F. B. Sloan, Cowan; W. M. Freeman, Hall's Hill; J. W. Sharber, Spring Hill; J. B. Harland, Columbia; B. F. Keys, Eagleville; W. L. Davies, Brunswick; F. Bogart, Sweetwater; A. J. Weldon, Paris Landing; T. K. Powell, Dancyville; Richard Cheatham, J. G. Sinclair, John P. McFarland, Nashville; R. P. Bush, Gallatin.

The following new members were elected and registered: N. D. Richardson, W. E. McCampbell, Richard Douglas, D. C. Day, J. M. Coyle, Judge W. G. Brien, J. R. Ferrell, F. M. Ferriss, T. G. Shannon, C. L. Eves, W. P. Burdette, W. I. Edwards, Nashville; S. J. McGrew, Shelbyville; D. H. Shipman, Clifton, Wayne County; W. G. Bogart, Sweetwater; P. C. Walker, Dyersburg; C. S. Wright, H. Berlin, Chattanooga; H. M. Anderson, Sewanee; J. V. Martin, Hendersonville; W. G. Spencer, U.S.A.; F. Ferguson, Rich Creek; B. W. Nolin, Mount Pleasant; F. M. Capps, Coxburg; L. E. Webb, Clarksville; J. L. Watkins, Nashville.

The President's Address.

Dr. W. F. Glenn then delivered an address on the "Immortality of Man." The address was referred to the Publication Committee.

The Society then adjourned until 2 P. M.

Afternoon Session.

In the absence of the President and Vice-President, Dr. Lipscomb called the Society to order.

The following

New Members

were elected:

Drs. W. R. Townsend, South Pittsburg; E. W. Bailey, Nashville; A. H. Caldwell, Cynthiana; J. M. Zarecor, Murfreesboro'; R. J. Hoyle, Farmington, Tenn.

THE SECRETARY'S REPORT.

DR. C. C. FITE read his report, in which he argued that Tennessee should have a law, strictly enforced, to regulate the practice of medicine. She should have a well-drawn and accurately executed vital registration law. State and local boards of health should be better maintained, and when laws to protect the people come up before the General Assembly we should unitedly support them. The law, suggested to our law-makers recently, to better provide for the inspection of oils, should have passed.

DR. THOMAS LIPSCOMB read a paper containing many interesting reminiscences of the early history of the Society.

DR. J. S. NOWLIN then read an interesting paper on

VACCINATION AND SMALLPOX,

which was followed by a prolonged and interesting discussion by Drs. Grant, Fite, Roberts, Baxter, Noblett, T. L. Maddin, and Zarecor.

Dr. J. S. Nowlin offered the following resolution, which was adopted:

Whereas, The history of vaccination proves that vaccination is fully protective against smallpox, therefore

Resolved, That this Society does recommend and ask the State Board of Health to immediately institute such measures as will, at the earliest possible moment, secure a law requiring the vaccination of every infant born in this jurisdiction.

DR. ROBERTS gave notice that he would offer two amendments to the Constitution, one in regard to the censors and the other in relation to annual dues.

The Society then adjourned.

WEDNESDAY, APRIL 12.

The Society met at 10 o'clock, and was called to order by the President.

The following

NEW MEMBERS.

were elected: Drs. Norris, Centreville; W. L. Austin, J. S. Cain, J. L. Frey, Nashville; R. A. Harrington, Bold Spring.

The following members registered in addition to those previously reported: Drs. H. M. Bonner, Fayetteville; A. B. Tadlock, Knoxville; A. J. Swaney, Castalian Springs; C. C. Atchison, T. Menees, W. G. Ewing, T. A. Atchison, W. D. Haggard, W. T. Briggs, J. T. Arrington, Nashville.

DR. BAXTER extended to the Society an invitation to hold their next meeting in Chattanooga.

DR. TADLOCK spoke in behalf of Knoxville, and asked the Society to hold their next meeting in that city.

DR. POWELL favored meeting at Nashville every year.

Chattanooga was selected as the place of meeting for next year.

Memoirs of Drs. Walter Hightower; Sims, of Wartrace; C. K. Winston, of Nashville, and Randolph Knaffle, of Knoxville, were read, and after appropriate remarks by Drs. Jones, Lipscomb, Lindsley, and Menees, ordered to be published.

ELECTION OF OFFICERS.

The election of officers being next in order, Dr. A. B. Tadlock, of Knoxville, and Dr. T. A. Atchison, of Nashville, were nominated for *President*.

The result of the ballot was, Dr. Tadlock, 40, and Dr. Atchison, 35, and on motion of Dr. Atchison, the election was made unanimous.

The following were nominated for *Vice-Presidents:*

West Tennessee—W. W. Taylor, of Brownsville, who was elected without opposition.

Middle Tennessee—Dr. A. Morrison, of Nashville, Dr. S. Swaney, of Gallatin, Dr. F. B. Sloan, of Cowan. The ballot stood, Morrison, 41; Swaney, 19; Sloan, 10; and Dr. Morrison was declared elected.

East Tennessee—C. S. Wright, of Chattanooga, who was elected without opposition, other nominees being withdrawn.

Dr. C. C. Fite, present incumbent, was re-elected *Secretary* without opposition.

Dr. Deering J. Roberts was elected *Treasurer* without opposition.

Dr. Roberts moved

AN AMENDMENT TO THE CONSTITUTION,

establishing a judicial council instead of the Board of Censors, the judicial council to be composed of those who had been President of the State Medical Society, three of whom should constitute a quorum. As objection was made, the amendment lies over until next year.

The Society adjourned until 2 P.M.

AFTERNOON SESSION.

DR. A. B. TADLOCK read an admirable paper on *Femoral Hernia*.

DR. J. W. DAVIS, of Smyrna, sent an interesting account of a case of induced delivery that occurred in his practice. The paper was referred.

The committee to examine the Treasurer's accounts reported them correct.

By request, DR. GRANT opened a discussion on *Puerperal Fever*, which was participated in by Drs. McFarland, Vertrees, J. S. Nowlin, Williamson, J. W. Madden, and A. J. Sinclair.

DR. J. G. SINCLAIR introduced a patient showing the result of a burn to the eye, and detailed his treatment of the case.

DR. J. W. MCMURRAY was elected an active member.

DR. ROBERTS suggested some changes in the constitution and by-laws in regard to dues. The question was referred to a special committee, with instructions to report at the next meeting a new constitution and by-laws.

DR. W. D. HAGGARD presented a paper on *Ovarian Disease*.

The Society then adjourned, to meet in Chattanooga, the second Tuesday in April, 1884.

After adjournment, a handsome banquet was tendered by the resident physicians to the members of the State Society.

CORRESPONDENCE.

CALIFORNIA HEALTH RESORTS.

To the Editor of THE MEDICAL NEWS.

SIR: In an editorial in THE NEWS of March 17th, is a reference to the California climate, and to the health resorts of the southern part of that State.

Inasmuch as I have spent several months there for my own health, I think it possible that the result of my observations and experience may be of service to others. I reached San Francisco in December, 1878, after having spent some weeks at sea and a short time in Japan. I had left home on account of a chronic pulmonary trouble, and had gained considerably in flesh before I returned to America, but it was deemed best by my physician here, Dr. James L. Cabell, for me to spend the winter in California, and by the advice of Dr. Hammond, of San Francisco, an old army surgeon who had been stationed in all parts of the State, I went to San Diego. While there, I gained rapidly in flesh and strength, and my health has continued good ever since.

That San Diego is the best of the health resorts on the Pacific coast, for those who require a dry and equable climate, I have no doubt. I give below a table showing the number of clear, fair, cloudy, and rainy days in each month during a period of four years, and also tables showing the range of the thermometer and barometer during a period of five years. These tables were compiled from the reports of the signal officers at San Diego, and speak for themselves.

Table showing number of clear, fair, cloudy, and rainy days in each month of the years 1873, '74, '75, '76.

	JANUARY.				FEBRUARY.				MARCH.				APRIL.				MAY.				JUNE.			
	Clear.	Fair.	Cloudy.	Rainy.	Clear.	Fair.	Cloudy.	Rainy.	Clear.	Fair.	Cloudy.	Rainy.	Clear.	Fair.	Cloudy.	Rainy.	Clear.	Fair.	Cloudy.	Rainy.	Clear.	Fair.	Cloudy.	Rainy.
1873 .	16	9	3	3	7	8	2	11	8	15	6	2	11	11	7	1	3	6	4	1	6	19	5	0
1874 .	7	8	9	7	11	5	1	11	6	11	4	10	13	13	1	3	8	15	3	5	13	16	1	0
1875 .	8	12	3	8	8	13	4	3	14	14	0	3	10	15	3	2	9	16	3	3	10	18	1	1
1876 .	15	5	1	10	15	6	3	5	•17	6	3	5	12	13	3	2	11	14	5	1	0	18	11	1

	JULY.				AUGUST.				SEPTEMBER.				OCTOBER.				NOVEMBER.				DECEMBER.			
	Clear.	Fair.	Cloudy.	Rainy.	Clear.	Fair.	Cloudy.	Rainy.	Clear.	Fair.	Cloudy.	Rainy.	Clear.	Fair.	Cloudy.	Rainy.	Clear.	Fair.	Cloudy.	Rainy.	Clear.	Fair.	Cloudy.	Rainy.
1873 .	9	22	0	0	11	6	2	2	14	14	2	0	15	14	1	1	7	15	3	5	12	9	3	7
1874 .	5	20	3	3	10	20	1	0	14	12	1	3	9	15	0	7	12	10	3	5	15	15	0	1
1875 .	4	18	9	0	8	21	1	1	5	17	6	2	13	16	2	0	13	7	3	7	16	7	5	3
1876 .	8	17	6	0	9	21	0	1	13	13	3	1	12	10	8	1	18	8	2	2	18	9	2	2

Report of Signal Officer at San Diego, California, for the years mentioned in the table.

Every period of twenty-four hours in which rain falls, if even for half an hour, is called a rainy day; but a large proportion of the so-called rainy days are nearly clear between sunrise and sunset, the rain falling only at night.

	RANGE OF THERMOMETER.		RANGE OF BAROMETER.	
	Maximum.	Minimum.	Maximum.	Minimum.
1874.	October. 90°	December. 39°	30.32	29.74
1875.	Sept. & Oct. 88°	December. 38°	30.36	29.55
1876.	August. 74·4°	January. 44.8°	30.35	29.67
1877.	August. 94°	January. 40°	30.31	29.72
1878.	September. 100°	December. 35·4°	30.39	29.55

There are some points which are not mentioned in the above tables which are of very great importance. One of these, and, according to my own experience and that of other health seekers whom I met, by far the most important, is the diurnal variation of temperature. Nothing is more uncomfortable, certainly, to an invalid than a very sudden fall in the thermometer. At San Diego, during the three months I was there, the daily variation was never sufficient to cause discomfort. At Santa Barbara I saw the thermometer fall, on one occasion, nearly 30° (from 90° to 62°) in three hours, and while, of course, a fall of this magnitude is not nearly so much felt when the temperature is high as when it is lower, it is sufficient to cause decided chilliness and to necessitate a change of clothing.

Then another serious drawback to most of the health resorts in southern California which I visited, was the dust. Nor was San Diego by any means free from this objection, but it was less subject to winds and dust than any other place I visited, except the San Gabriel Valley. Fogs occasionally occur there (at San Diego), but as the town is on a bay, and seven miles from the sea, they are not so common as at most of the other resorts, and in the country, a few miles back, they never occur.

To send patients to San Diego, or any other health resort, who were far advanced in consumption, in the hope that they would be benefited by the change, would be the merest folly; yet it was not uncommon, during the winter of 1878 and '79, when I was there, for persons to come in the last stages of this disease, whose friends

expected a speedy recovery. It is needless to say that such cases were not improved, and had far better have staid at home. It was, however, the unanimous opinion of those who had tried all the resorts on the coast, that San Diego possessed decidedly the best climate. At that time, though, there was no railroad connection with other points, and for those who were fond of amusement and society the town was extremely dull; and it was on this account, and on this alone—so far as I could judge—that it was not more popular.

I was therefore led to the conclusion, that of all the California health resorts, San Diego and its vicinity was unquestionably the best. I mention the surrounding country, especially, because quite a number of persons found that they felt more comfortable, and improved more rapidly a short distance back from the bay. One of my patients, who has spent the past winter there, found it advisable to go back into the country.

What the relative merits of southern California and Colorado are, I am not prepared to say. The atmosphere at Manitou Springs was so light, that in my own case the respiration was seriously embarrassed, and I was only too glad to get away after spending only a day or two there. To those whose respiratory surface was not lessened, the air seemed most exhilirating and beneficial.

There are certain troubles incident to the trip across the continent which to a well person would seem trivial, but which are very annoying to an invalid. One of these is the alkali dust which gets into the throat and lungs, and causes great annoyance, and frequently sets up a troublesome cough, or aggravates one already present. Another trouble is that the air becomes so much rarefied that the breathing is uncomfortable if the respiratory surface has been much diminished. I found it necessary to lie down a part of the time, and was told that this was frequently necessary.

These seem to be very trivial matters; yet they are important to an invalid, and should be remembered in selecting a sanitarium.

Yours, etc.,
Wm. C. Dabney, M.D.

Charlottesville, Va., April 3, 1883.

BROMIDE OF POTASSIUM TO COUNTERACT THE UNPLEASANT EFFECTS OF QUININE.

To the Editor of The Medical News.

Sir: It occurred to me it might be interesting to call your attention to the effect bromide of potassium exerted over the cerebral congestion following a dose of bisulphate of quinine. The patient, a lady of rather delicate constitution, had a miscarriage, and I saw the case in connection with Dr. Beal, of Washington. During the second week considerable fever was manifest, the temperature never falling below 100° F., and rising to 105° F. Drugs could not be retained by the stomach, and a rectal injection of ten grains of bisulphate of quinine was ordered to be taken every three hours. Following the third injection, a severe headache with buzzing in the ears, accompanied by slight hallucinations. I being with the patient at the time, gave her an enema of thirty grains of bromide of potassium, and before fifteen minutes had elapsed all the distressing symptoms disappeared, and the patient passed into a quiet sleep. No other drugs had been used. Milk and beef tea the diet. I do not remember seeing these effects of the bromide recorded. If there is anything new in this observation it might be worth professional attention.

Very respectfully yours,
J. Alban Kite, M.D.

U.S.S. Fish Hawk, April 13, 1883.

ŒDEMA UVULÆ THREATENING LIFE.

To the Editor of The Medical News.

Sir: Your issue of March 31st contains an article on this subject by Dr. Chas. H. Carter, of Chicago, Ill., with a request for further reports of such cases. The following facts may be of interest in this connection:

Otto T., æt. thirty, single, was admitted to the German Hospital, on March 5th, suffering from acute articular rheumatism, the case belonging to Dr. G. W. Vogler, one of the visiting physicians to the hospital. The patient made a rapid recovery, and then had an attack of acute tonsillitis of a mild type, the treatment of which consisted of simple astringents. He did well until midnight of March 30th, when I was hastily summoned to see him in the male medical ward, and found him completely exhausted from impending suffocation.

The cause of his struggles was at once apparent. The pharynx and tonsils were much congested; the uvula enormously enlarged, filled with fluid, and reached down to the epiglottis. There being no time to lose, I simply seized the uvula with a tenaculum and amputated a portion of it with a pair of scissors, which was followed by immediate relief and shrinking of the organ.

Treatment with the astringent gargle was continued, and patient discharged, a few days later, cured.

Most respectfully yours,
John S. Miller,
Resident Physician.

German Hospital, April 11, 1883.

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

The Holmes Banquet.—The dinner given by the medical profession of New York City in honor of Dr. Oliver Wendell Holmes, on the evening of April 12, 1883, was an occasion which will be long remembered by those who had the good fortune to be present.

The great dining hall at Delmonico's was filled to its utmost capacity, about two hundred and twenty persons being present, and within a very short time after the Committee having charge of the matter had announced their readiness to receive subscriptions, it was embarrassed by the number of applications for tickets.

The five long tables running at right angles to the guest table, placed on a slightly raised dais, reminded one of the dinner given by the Lord Mayor of London to the International Medical Congress. At the raised table sat Dr. Holmes, at the right of the Chairman, Dr. Fordyce Barker. On the right of Dr. Holmes were Hon. W. M. Evarts, Dr. J. T. Metcalfe, Mr. Geo. Wm. Curtis, Dr. S. O. Vanderpoel, Dr. J. S. Billings, Dr. L. A. Sayre, Dr. T. A. Emmet, and Dr. A. C. Post; while on the left of the Chairman were Bishop Clark, of Rhode Island, Mr. Whitelaw Reid, Dr. J. C. Dalton, Dr. S. Weir Mitchell, Dr. T. G. Thomas, Dr. Wm. Detmold, Dr. T. M. Markoe, Dr. James Anderson, and Dr. I. E. Taylor.

At the other tables were seated the leading members of the medical profession of New York, the presiding officers being Drs. C. I. Pardee, J. H. Anderson, Leroy M. Yale, E. G. Loring, and R. F. Weir.

The decorations were simple and in good taste, consisting of cut flowers and pots of flowering and bright-leaved plants. The menu was an elaborate affair in the form of a small book, bound in thick plush, the cover having a device in gilt representing a scalpel

and a pen crossed within a wreath. At the head of the menu were the lines: "You know your own degree; sit down; at first and last a hearty welcome." This quotation was the more appropriate, since each guest and ticketholder had received a plan of the tables, showing the location of all the diners, his own being specially marked by a red check. The dinner was, of course, all that could be desired so far as dishes, wines, and service are concerned. The sherbet was served, *à la Yorick*, in small skulls made of white wax.

The programme of toasts was as follows:

"The hours now come;
The very minute bids thee ope thine ear;
Obey and be attentive." —"*The Tempest.*"

Greeting by Dr. Fordyce Barker.

"Sir, you are very welcome to our house;
This must appear in other ways than words;
Therefore I scant the breathing courtesy."
—"*Merchant of Venice.*"

I. Our Guest.

"One would say, here is a man with such an abundance of thought. He is never dull, never insincere, and has the genius to make the reader care for all that he cares for." —*Emerson.*

Response by Dr. Oliver Wendell Holmes.

II. The Clergy.

"He was a scholar, and a ripe and good one, exceeding wise, fair spoken and persuading." —*King Henry VIII.*

Response by Bishop T. M. Clark, of Rhode Island.

III. The Bar.

"Why might that not be the skull
Of a lawyer? Where be his quiddets now?"
—"*Hamlet.*"

Response by the Hon. Wm. M. Evarts.

IV. The Medical Profession.

She honors herself in honoring a favorite son.

Response by Dr. T. Gaillard Thomas.

V. Literature.

"A kind of medicine in itself."
—"*Measure for Measure.*"

Response by George William Curtis.

VI. The Press.

"But words are things, and a small drop of ink,
Falling like dew upon a thought, produces
That which makes thousands, perhaps millions, think."
—*Byron.*

Response by Whitelaw Reid.

"Good night, good night! Parting is such sweet sorrow,
That I shall say good night till it be morrow."
—"*Romeo and Juliet.*"

About 10 P.M., the Chairman, Dr. Fordyce Barker, rapped for silence, and, in a brief and humorous speech, introduced the guest of the evening, and called on Dr. A. H. Smith to complete the greeting.

Dr. Smith responded in verse as follows:

You've heard of the deacon's one-hoss shay
Which, finished in Boston the self-same day
That the City of Lisbon went to pot,
Did a century's service, and then was not.
But the record 's at fault which says that it bust
Into simply a heap of amorphous dust;
For after the wreck of that wonderful tub,
Out of the ruins they saved a hub;
And the hub has since stood for Boston town,
Hub of the Universe—note that down.
But an ordinary hub, as all will own,
Must have something central to turn upon,
And, rubber-cushioned, and true, and bright,
We have the axle here to-night.

Thrice welcome, then, to our festal board
The doctor-poet, so doubly stored
With science as well as with native wit;
Poeta nascitur, you know, *non fit.*
Skilled to dissect with knife or pen,
His subjects dead or living men;
With thoughts sublime on every page
To swell the veins with virtuous rage,
Or with a syringe to inject them
With sublimate to disinfect them;
To show with demonstrator's art,
The complex chambers of the heart,
Or armed with a diviner skill
To make it pulsate at his will;
With generous verse to celebrate
The loaves and fishes of some giver,
And then proceed to demonstrate
The lobes and fissures of the liver;
To soothe the pulses of the brain
With poetry's enchanting strain,
Or to describe to class uproarious
Pes hippocampi accessorious;
To nerve with fervor of appeal
The sluggish muscles into steel,
Or, pulling their attachments, show
Whence they arise and where they go;
To fire the eye by wit consummate,
Or draw the aqueous humor from it;
In times of peril give the tone
To public feeling called backbone,
Or to discuss that question solemn
The muscles of the spinal column.
And now I close my artless ditty
As per agreement with committee,
And making place for those more able,
I leave the subject on the table.

Yet one word more. I've had my pride
As *medicus* most sorely tried,
When Englishmen who sometimes show
Of things American, you know,
An ignorance that is melancholy;
As Dr. Holmes is very jolly,
Assume that he must therefore be
A Doctor of Divinity.
So to avoid all chance of wrong
To medicine, or church, or song!
Let Dr. Holmes discarded be
For Oliver Wendell Holmes, M.D.

And now, for I really must come to an end,
May the fate of the chaise be the fate of our friend.
May he never break down, and never wear out,
But a century old, or thereabout;
Not feeling the weight of the years as they fly,
Simply stop living when ready to die.

This was received with great laughter and applause.

When Dr. Holmes arose to reply, the banqueters arose with him, and gave him three cheers and a tiger. His reply was as follows:

Have I deserved your kindness? Nay, my friends,
While the fair banquet its illusion lends
Let me believe it, though the blood may rush
And to my cheek recall the maiden blush
That o'er it flamed with momentary blaze
When first I heard the honeyed words of praise,
Let me believe it while the roses wear
Their bloom unwithering in the heated air;
Too soon, too soon their glowing leaves must fall,
The laughing echoes leave the silent hall,
Joy drop his garland, turn his empty cup,
And weary labor take his burden up,—
How weighs that burden they can tell alone
Whose dial marks no moment as their own.

Am I your creditor? Too well I know
How Friendship pays the debt it does not owe,
Shapes a poor semblance fondly to its mind,
Adds all the virtues that it fails to find,
Adorns with graces to its heart's content,
Borrows from love what nature never lent,
Till what with halo, jewels, gilding, paint,
The veriest sinner deems himself a saint.

Thus while you pay these honors as my due
I owe my value's larger part to you,
And in the tribute of the hour I see
Not what I am, but what I ought to be.

Friends of the Muse, to you of right belong
The first staid footsteps of my square-toed song;
Full well I know the strong heroic line
Has lost its fashion since I made it mine;
But there are tricks old singers will not learn,
And this grave measure still must serve my turn.
So the old bird resumes the self-same note
His first young summer wakened in his throat;
The self-same tune the old canary sings,
And all unchanged the bobolink's carol rings;
When the tired songsters of the day are still
The thrush repeats his long-remembered trill;
Age alters not the crow's persistent caw,
The Yankee's "Haow," the stammering Briton's "Haw;"
And so the hand that takes the lyre for you
Plays the old tune on strings that once were new.
Nor let the rhymester of the hour deride
The straight-backed measure with its stately stride;
It gave the mighty voice of Dryden scope;
It sheathed the steel-bright epigrams of Pope;
In Goldsmith's verse it learned a sweeter strain;
Byron and Campbell wore its clanking chain;
I smile to listen while the critic's scorn
Flouts the proud purple kings have nobly worn;
Bid each new rhymer try his dainty skill
And mould his frozen phrases as he will;
We thank the artist for his neat device;
The shape is pleasing, though the stuff is ice.

Fashions will change,—the new costume allures,
Unfading still the better type endures;
While the slashed doublet of the cavalier
Gave the old knight the pomp of chanticleer,
Our last-hatched dandy with his glass and stick
Recalls the semblance of a new-born chick;
(To match the model he is aiming at
He ought to wear an egg-shell for a hat);
Which of these objects would a painter choose,
And which Velasquez or Van Dyke refuse?

When your kind summons reached my calm retreat,
Who are the friends, I questioned, I shall meet?
Some in young manhood, shivering with desire
To feel the genial warmth of fortune's fire,—
Each with his bellows ready in his hand;
To puff the flame just waiting to be fanned;
Some heads half-silvered, some with snow-white hair,—
A crown ungarnished glistening here and there,
The mimic moonlight gleaming on the scalps
As evening's Empress lights the shining Alps,
But count the crowds that throng your festal scenes,
How few that knew the century in its teens!

Save for the lingering handful fate befriends,
Life's busy day the Sabbath decade ends;
When that is over, how with what remains
Of nature's outfit, muscle, nerve, and brains?

Were this a pulpit I should doubtless preach,
Were this a platform I should gravely teach,
But to no solemn duties I pretend
In my vocation at the table's end,
So as my answer let me tell instead
What Landlord Porter,—rest his soul!—once said.

A feast it was that none might scorn to share;
Cambridge and Concord's demigods were there,—
"And who were they?" You know as well as I
The stars long glittering in our Eastern sky,—
The names that blazon our provincial scroll
Ring round the world with Briton's drumbeat roll!
Good was the dinner, better was the talk;
Some whispered, devious was the homeward walk;
The story came from some reporting spy,—
They lie, those fellows,—O, how they do lie!
Not ours those foot-tracks in the new-fallen snow,—
Poets and sages never zig-zagged so!

Now Landlord Porter, grave, concise, severe,
Master, nay Monarch in his proper sphere,
Though to belles-lettres he pretended not,
Lived close to Harvard, so knew what was what,
And having bards, philosophers and such,
To eat his dinner, put the finest touch
His art could teach, those learned mouths to fill
With the best proofs of gustatory skill,
And finding wisdom plenty at his board,
Wit, science, learning, all his guests had stored,
By way of contrast, ventured to produce
To please their palates, an inviting goose.

Better it were the company should starve
Than hands unskilled that goose attempt to carve;
None but the master-artist shall assail
The bird that turns the mightiest surgeon pale.

One voice arises from the banquet hall,—
The landlord answers to the pleading call;
Of stature tall, sublime of port he stands
His blade and trident gleaming in his hands;
Beneath his glance the strong-knit joints relax
As the weak knees before the headsman's axe.
And Landlord Porter lifts his glittering knife
As some stout warrior armed for bloody strife;
All eyes are on him; some in whispers ask
What man is he who dares this dangerous task?
When, lo! the triumph of consummate art,
With scarce a touch the creature drops apart!
As when the baby in his nurse's lap
Spills on the carpet a dissected map.

Then the calm sage, the monarch of the lyre,
Critics and men of science all admire,
And one whose wisdom I will not impeach,
Lively, not churlish, somewhat free of speech,
Speaks thus: "Say, master, what of worth is left
In birds like this, of breast and legs bereft?"
And Landlord Porter, with uplifted eyes,
Smiles on the simple querist, and replies:
"When from a goose you've taken legs and breast,
Wipe lips, thank God, and leave the poor the rest!"

Kind friends, sweet friends, I hold it hardly fair
With that same bird your minstrel to compare,
Yet in a certain likeness we agree,
No wrong to him, and no offence to me;
I take him for the moral he has lent,
My partner,—to a limited extent.

When the stern landlord whom we all obey
Has carved from life its seventh great slice away,
Is the poor fragment left in blank collapse
A pauper remnant of unvalued scraps?

I care not much what Solomon has said,
Before his time to nobler pleasures dead;
Poor man! he needed half a hundred lives
With such a babbling wilderness of wives!
But is there nothing that may well employ
Life's winter months,—no sunny hour of joy?

While o'er the fields the howling tempests rage,
The prisoned linnet warbles in its cage;
When chill November through the forest blows,
The greenhouse shelters the untroubled rose,
Round the high trellis creeping tendrils twine,
And the ripe clusters fill with blameless wine;
We make the vine forget the winter's cold,
But how shall age forget its growing old?

Though doing right is better than deceit,
Time is a trickster it is fair to cheat;
The honest watches ticking in your fobs,
Tell every minute how the rascal robs.
To clip his forelock and his scythe to hide,
To lay his hour-glass gently on its side,
To slip the cards he marked upon the shelf
And deal him others you have marked yourself,
If not a virtue, cannot be a sin,
For the old rogue is sure at last to win.

What does he leave when life is well-nigh spent
To lap its evening in a calm content?
Art, Letters, Science, these at least befriend
Our day's brief remnant to its peaceful end,—

Peaceful for him who shows the setting sun
A record worthy of his Lord's "Well done!"

When he, the Master whom I will not name,
Known to our calling, not unknown to fame,
At life's extremest verge half conscious lay,
Helpless and sightless, dying day by day,
His brain, so long with varied wisdom fraught,
Filled with the broken enginery of thought,
A fitting vision often would illume
His darkened world, and cheer its deepening gloom,—
A sunbeam struggling through the long eclipse,—
And smiles of pleasure play around his lips.
He loved the Art that shapes the dome and spire
The Roman's page, the ring of Byron's lyre,
And oft when fitful memory would return
To find some fragment in her broken urn,
Would wake to life some long-forgotten hour,
And lead his thought to Pisa's terraced tower,
Or trace in light before his rayless eye
The dome-crowned Pantheon printed on the sky;
Then while the view his ravished soul absorbs
And lends a glitter to the sightless orbs,
The patient watcher feels the stillness stirred
By the faint murmur of some classic word,
Or the long roll of Harold's lofty rhyme,
"Simple, erect, severe, austere, sublime,"—
Such were the dreams that soothed his couch of pain,
The sweet nepenthe of the worn-out brain.

Brothers in art, who live for other's needs
In duty's bondage, mercy's gracious deeds,
Of all who toil beneath the circling sun
Whose evening rest than yours more fairly won?
Though many a cloud your struggling morn obscures,
What sunset brings a brighter sky than yours?

I, who your labors for a while have shared,
New tasks have sought, with new companions fared,
For Nature's servant far too often seen
A loiterer by the waves of Hippocrene;
Yet round the earlier friendship twines the new,
My footsteps wander, but my heart is true,
Nor e'er forgets the living or the dead,
Who trod with me the paths where science led.

How can I tell you, O my loving friends,
What light, what warmth your joyous welcome lends
To life's late hour? Alas! my song is sung,
Its fading accents falter on my tongue,
Sweet friends, if shrinking in the banquet's blaze,
Your blushing guest must face the breath of praise,
Speak not too well of one who scarce will know
Himself transfigured in its roseate glow;
Say kindly of him what is,—chiefly,—true,
Remembering always he belongs to you;
Deal with him as a truant, if you will,
But claim him, keep him, call him brother still!

Bishop Clark, upon being called upon to speak for the clergy, after alluding to the fact that originally the functions of the priest and of the doctor were the same—being the exorcising of the bad spirits who were supposed to be the authors of both gastric and moral diseases, proceeded to eulogize Dr. Holmes as a physician of the mind. "I wonder," said the Bishop, "if the Doctor knows how much sunlight he has brought into many a poor parson's sermon, and what a relief it sometimes is to turn from the Athanasius of the school to the Autocrat of the Breakfast Table; from the dry, dreary pages of Turretin to the Deacon's Masterpiece, and from Poole's Synopsis to poor Elsie Venner. [Applause.] We of the clergy are very proud of Dr. Holmes, because he is, as it were, one of us. If he had not had a father, the Autocrat would not have been; and that father was a clergyman; so that the Doctor is really one of our productions, and in a certain sense we feel that we may take the credit of all that he has ever said or written. [Laughter.] We are under great obligations to the father for giving us such a son. [Applause.] If the young man could have been induced to study for the ministry, what a preacher he would have made! It might have been necessary that he should curb his preachings a little if he had mounted the pulpit, and perhaps to modify some of his opinions in order to have become a sound divine. It may be better as it is; it is not every Pegasus that works well in harness.

"In taking up the other day my old, well-worn, green-covered copy of 'Holmes' Poems,' I was surprised by the date on the title-page—1836—within three years of half a century ago. Strangely enough, in the preface to this book he speaks of himself as an actor, who, on the occasion of his last appearance on the stage, 'folds his robes and makes his bow to the audience.' 'I now willingly retire,' he says, 'to more quiet labors, which, if less exciting, are more certain to be acknowledged as useful and received with gratitude.' Our veteran Professor had then reached the mature age of twenty-seven, but his sun was actually just rising. It has blazed away pretty steadily ever since. Long may it be before that sun goes down in glory." [Applause.]

In response to the toast of "the Bar," Mr. Evarts spoke as follows:

"Dr. Barker and Gentlemen of the Medical Profession: It gave me the greatest delight to be thought by your profession to be worthy to represent my own in joining in the tribute to the genius and worth of Dr. Holmes, which all the professions equally delight in sharing. I confess to a considerable satisfaction in the admirable impression which these collected members of your noble profession have produced upon me, and, if you will allow me to say it, how much pleasanter it was to be asked to meet three hundred doctors than to ask one to meet you. An English traveller, in the early part of the century, a lawyer like myself, had found in an old German book on medicine from a very great and eminent physician, something, you may imagine, not of a humorous form, for he spoke in the greatest seriousness, but something of oddity. This writer, attracting attention to the valuable instructions of his work, and to the great power and services of his profession, laid down this sweeping proposition—that all the diseases, all the ills that flesh is heir to, all accidents requiring surgical aid, all had their origin, all were bestowed upon the human race in order that a skilful and learned profession might be educated by their means. I do not know but that after all at bottom there is a good deal of feeling on the part of the three learned professions that that is the true view of human affairs. Estate, body, and mind they make up, do they not? they are all that is visible, all that is interesting, all that is important in human affairs. And, abandoning in our profession the Latin earlier than you of the clergy in your prayers, or you of the medical profession in your prescriptions, we all have the same word to cover our relations respectively to human affairs. The lawyer has the care of estates and of interests, the clergyman the care of souls, and the physician the care of the body; and as the sheep are for the shepherd, so those taken care of are for those who take care of them.

"I have pointed out once before to an assembly of young physicians the striking advantage which at the start you gentlemen had, for though, alas, everybody has not an estate, and everybody has not a mind, yet everybody has a body. And, although we thus hunt the human race in different paths, as civilization opens them to us, we are all sure to be in at the death; and, although it is a cheerless moment, yet to us there are assuaging circumstances. I draw one interesting discrimination in favor of that profession so well represented to night by the Bishop, in contrasting our relations to mankind—that where members of his

profession were sent out, as we all know, as sheep among wolves, we and you are sent out as wolves among sheep. [Laughter.] But we know enough not to pursue with any of our hostilities the clerical profession, although they tempt us by that guise of sheep [laughter], for we know that they are not sheep [laughter], and it is they who have a disguise, and not we who go in the midst of them. Now, this German doctor had this truth at last, that for the instruction of mankind, and for the development of the great intelligence, the great philanthropy and the great service that the different professions yield to mankind, these opportunities and these occasions were rendered in all the scheme of human life. May we not vary, then, the language which the great player used for human affairs from an analogy to his profession, and may we not wisely say

> "All the world's a school,
> And all the men and women in it scholars!

"Dr. Holmes has the advantages of being born and living near to Boston—a place of which no one learns early in life without feeling it a great advantage to have done so, and no one perhaps first learned of late in life without feeling that he is glad he has seen it before he dies. Having the advantage myself of having been born and bred there, I can only compare notes with Dr. Holmes upon the question, which of us he thinks, on the whole, was the wiser—I in leaving it as soon as I had got all the good out of it that was to be had, and looking for the wider sphere of New York for this exercise of my profession of a wolf among sheep. As for the fame that New York can ever bestow upon a resident and lover of Boston, as Dr. Holmes is, there is nothing in that. The only curiosity the Doctor had in this matter of fame, was to see how a Boston fame would sound echoed in New York, and I think I may say that it sounds very well to him for there is not a note or tone in the great capacity of this vast city less sweet. I have never known how the Boston people were able to put up so long with Dr. Holmes, who, while he furnished a great deal of reputation to Boston, took also a principal share of the reputation of Boston. Sir Henry Maine says, that a traveller repeating a visit to New Zealand, and inquiring for an old and a wise man, whom he had noticed on his previous visit, was told by the New Zealand chief: 'Well, he gave us so much good advice that we were obliged to put him away.' But our physician curbs even the natural ferocity of the Boston people, and while, by the methods of conveyance now in use, Dr. Holmes can slip away into so ample a heart as New York opens to him, he need not feel afraid that it will be necessary for the Boston people to put him away.

"And now, gentlemen, is it not fit, as we are all professional men, as the rest of the world are shut out, and as what is said here to-night will never go any further, [laughter]—is it not fit for us—does not our character for truth require us to admit that we are really the saviours and protectors of society? Why should we hide it even from ourselves? Let us nerve ourselves from these reflections to move in a more animated, more vigorous, more comprehensive pursuit of our several interests. Let us understand that the laborer is worth of his hire [laughter], and that those who are not willing to be aided by professional skill in parting with their property—and with their lives—are unworthy of serious consideration."

DR. T. GAILLARD THOMAS, responding to the toast of "The Medical Profession," said, that where the fame of the physician ordinarily ended, that of Dr. Holmes just began; and that he, more than any man of his profession, had bridged over that chasm which from time immemorial, has existed between physicians and the world, and has brought the profession of medicine into pleasant, agreeable contact with the world. He told a story related to him by an officer of the army, who once had with him as guide upon a scouting expedition, an especially grim and silent old hunter, upon whom all efforts of the officer to establish friendly relations seemed to be wasted. But one night the colonel was startled by a series of chuckles and strange and discordant noises, proceeding from the throat of the guide, and on investigation found that he had gotten hold of the officer's copy of Holmes' poems, and was slowly spelling out the legend of "The Spectre Pig," and henceforth he had the key to the old trapper's heart.

It was evident that with all his many years experience of praise in all its forms, this tribute was something new to Dr. Holmes; he leaned forward in his chair and listened intently, shaking with laughter at the close.

In concluding his response, Dr. Thomas said:

"And now, this man who for so many years has been known to us in spirit makes himself manifest to us in the flesh; he whom we have so long seen through a glass darkly we now see face to face, and to us is given the glorious privilege of telling him how thoroughly we appreciate his life-work; how sincerely his name is reverenced among us, and how truly he is beloved. As I look around it seems to me that I see before me a better representation of the dignity and the talent of medicine in New York than it has ever been my good fortune to have seen before. I feel sure that I give honest voice to the sentiment of every man within the range of my voice when I turn to our guest and say Welcome, thrice welcome, most cordially welcome, Doctor Holmes, to the city of New York. As in the monarchial towns of Europe on such an occasion as this you would be offered the freedom of the city, so do we, in the same spirit, in this our republican capital, throw wide open to you the portals of our homes and of our hearts. By that warmth of nature which has brought you into sunny contact with the whole world, by that genial, gentle sympathy which has endeared you to all who knew you; by that subtle genius which has so felicitously combined in you the attributes of philosopher, of poet, and of physician; by that nobility of spirit, that loftiness of soul which is so beautifully illustrated in your daily life, we here claim you proudly, and joyously hail you as our colleague, our friend, and our brother. Henceforth your joys shall be our joys and your sorrows our sorrows. I pledge you in the name of my comrades and brothers, that the kindly regard that we now offer you shall live from the pleasant hour we now enjoy together to that far distant one when you shall leave us to occupy your predestined niche in the Walhalla of fame, surrounded as with a garment by that glory which kills the sepulchre, and embalms a name that it may live among the immortal ones that were not born to die."

"Literature" was the next toast, and was responded to by GEORGE WILLIAM CURTIS, who began by remarking that "Medicine has spoken the praises of our guest, and the Church and Law. And as the Church disposes satisfactorily of a man's mind, and Medicine summarily of his body, and Law most effectually of his estate, what remains for Literature to add of a doctor's subject so thoroughly disposed of, but that in literature he has chosen to build his most enduring monument.

"All of the Faculties have claimed him, and have spoken his praises. Each in turn has cried: 'Hail, Thane of Glamis! Hail, Thane of Cawdor!' And now comes Literature, with 'All hail, thou that shalt be king hereafter!'"

It was nearly midnight when MR. WHITELAW REID,

of the *New York Tribune*, rose to reply to the last toast, "The Press." He said:

"If you are finding out by his poor words and halting manner how little and unimportant the mysterious 'We' of a big newspaper may be, what do you think of your own exhibition? There are here present at least a dozen of you from whom I myself have heard the most solemn and magisterial instructions as to how one should live. Avoid late dinners; avoid crowded rooms; eat simply; drink sparingly; don't smoke; three courses for your dinner and a single glass of wine; keep your dining-room cool; avoid drafts; be sure to have the air pure and fresh; never sit over an hour at table! Ah, yes; those are the familiar formulas. Every one of you remembers them; every one of you has given them a thousand times, and taken a good fee for it every time. Now we've got you out from behind the screen. This must be what you meant by it. This is the way you live. This is where the fees go. The united skill of two hundred doctors, concentrated upon the single problem of hygiene, how to produce for themselves the best and most wholesome way of dining, has resulted in this. [Laughter.] Well, well, it may be naughty, but it's nice; and we are more obliged than we can tell you for being shown at last, so satisfactorily and on the highest medical authority, just what 'Plain Living and High Thinking' mean.

"The newspapers have been spoken of as New York's Autocrats of the Breakfast Table. Oh, no; New York has no Autocrat of the breakfast table. In all the world there is only one; we shall never see his like again, and we are sure of him in New York only for to-night.

"Call us not autocrats, then; but mere doctors, like the rest of you. We too give prescriptions, and, like you, are often in doubt as to whether the patients will take them. We too are sometimes called on for remedies when we haven't a bit more idea than you what is the matter with the patients or what will help them; and we then are often as conscientious as you, and carefully disguise under our wise-looking prescription the formula for a harmless bread pill. Like you, we work solely for the good of humanity; but like you, while we are at it, we also expect humanity to find us a good living. Like you, we are occasionally mistaken in our diagnosis; and like you, we have a bad half-hour of it when our patients find us out, refuse our nostrums, and resolutely declare that they are suffering from no such maladies as we describe. A wise doctor, under such circumstances, humors his patient, and a wise journalist sometimes finds it best, however much against his grain, to let the people have their own way!"

Speaking of Dr. Holmes, he said: "If we were to judge indeed from the brilliant record of his performances, we might say that he really has the quality editors only pretend to; that he knows something about everything, and can write on anything. Consider the round of his accomplishments—as physician, medical lecturer, medical author; as microscopist, and photographer; as the best living writer of after-dinner poems; as the author of some of our tenderest and some of our most ringing lyrics; above all, to give in a word reason enough for a great fame, as author of *The Chambered Nautilus*, a perfect poem, if the English language holds one. Then recall his work in a series of magazine papers that form an absolute era in American literature, and give him a place alone—the only autocrat. Then remember his novels. We talk sometimes of looking, among our living writers, for the coming American novelist. If we mean one of unique type and of the first rank, he has come. Why seek farther than the author of *Elsie Venner* and *The Guardian Angel?*

"Your honored guest, Mr. Chairman, must have seemed to every one here the youngest man at your table to night. Yet we know, and perhaps may venture to say, that save for the ever-youthful spirit he is no longer young. The man who has written thirty-two successive annual poems for the class of 1829 must not be surprised that all the world knows by heart, if not his precise age, at least how long he has been out of college. It is one of the pleasantest things connected with his formal relinquishment of some of the burdens he has been bearing that he has the right, in this mellow Indian Summer of his fruitful life, to know that his fame is still a growing one. The very flash and glitter of his wit have sometimes blinded men's eyes to the rich and generous qualities that lay beneath it. Lowell painted him as

> "'A Leyden-jar, always full-charged, from which flit
> The electrical tingles of hit after hit.'"

On the conclusion of Mr. Reid's speech, Dr. Barker referred to a number of physicians who had sent letters of regret, and then called for a bumper to absent friends. It was drunk standing; the company sang "Auld Lang Syne" right heartily as a response, and then separated.

NEW ORLEANS.

(*From our Special Correspondent.*)

The Louisiana State Medical Society met in Shreveport, April 4th. The attendance was very large, and the proceedings were interesting and encouraging. The following congratulatory resolution was telegraphed to the Kentucky State Medical Society, being first unanimously approved by vote of the Society:

"The Louisiana State Medical Society, now in session here, sends fraternal greeting to the Kentucky State Medical Society, and trust they stand shoulder to shoulder with us in upholding the time-honored Code of Ethics of the American Medical Association."

The reply was equally expressive of a determination to sustain the Code:

"The Kentucky State Medical Society cordially reciprocate the greetings of their brethren of the Louisiana State Medical Society, and emphatically endorse the sentiments of allegiance to the Code and devotion to the honor and dignity of American medicine."

Before adjournment thirty-two members pledged themselves to pay annually into the treasury of the society, ten dollars, being double the annual dues.

The Charity Hospital.—An effort is being made in this State to build additional wards to the Charity Hospital, by voluntary contributions.

Smallpox is on the increase—86 deaths last week, 69 the week before, and 56 the week before that. From January 1st to April 1st there have been 1,167 cases, with 428 deaths. White, 523 cases, 144 deaths; colored, 644 cases, 284 deaths. The percentage is thus largely in favor of the whites, both as regards cases and deaths.

The Sanitary Council of the Mississippi Valley held its session in Jackson, Miss. The New Orleans Auxiliary Sanitary Association was highly complimented. The Louisiana State Board of Health sent overtures offering to coöperate. The offer was "accepted in the spirit in which it was made," a statement capable of several interpretations. From the proceeding of the Council, it is very evident that unless the health authorities of New Orleans are candid and impartial this summer with regard to contagious diseases, yellow fever and the like, New Orleans will be the greatest sufferer. The citizens of New Orleans begin to recog-

nize this now, though a short time ago a man who reported a case of yellow fever as such, except in a grave epidemic, laid himself liable to ostracism.

THE NEW ORLEANS MEDICAL AND SURGICAL JOURNAL has again changed its staff. Dr. Jno. Godfrey, of the U. S. Marine Hospital Service has gone out, and Dr. R. Matas has taken his place. No reason is assigned for the rapid change.

THE MARYLAND MEDICAL JOURNAL announces that it will appear as a weekly, on May 3d, and will be published every Thursday. It will continue under the able editorial management of Drs. Ashby and Cordell.

STATE MEDICAL SOCIETY MEETINGS.—The Medico-Chirurgical Society of Maryland meets at Baltimore, and the Texas State Society at Tyler, on Tuesday the 24th. The South Carolina Medical Association meets at Yorkville, on Wednesday the 25th.

SANITARY CONVENTION OF MICHIGAN.—A sanitary convention will be held in Reed City, Michigan, under the auspices of the State Board of Health, on April 26th and 27th. A number of valuable papers will be read, and it confidently expected that much good will result to the State.

THE MEDICAL ASSOCIATION OF THE DISTRICT OF COLUMBIA held its annual meeting a few days ago, and the following officers were elected for the ensuing year:

President.—Dr. D. R. Hagner.
First Vice-President.—Dr. D. W. Prentiss.
Second Vice-President.—Dr. F. A. Ashford.
Secretary.—Dr. J. F. Hartigan.
Treasurer.—Dr. George L. Magruder.

RESIGNATION OF PROFESSOR DETMOLD.—Professor William Detmold, who, for about thirty-five years, has held a surgical clinic at the College of Physicians and Surgeons, of New York City, has resigned that position. Dr. R. F. Weir has been elected to fill the vacancy thus created in the chair of clinical surgery.

THE ANNUAL COMMENCEMENT OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF PENNSYLVANIA was held on April 13th. The degree of Doctor in Medicine was conferred on ninety-nine candidates. The Faculty valedictory was delivered by R. A. F. PENROSE, M.D., Professor of Obstetrics and Diseases of Women and Children.

A VOLUNTARY FOURTH YEAR AT THE UNIVERSITY OF PENNSYLVANIA.—The University of Pennsylvania has completed arrangements in its Department of Medicine for a voluntary fourth year of instruction, which it is hoped will be availed of by a gradually increasing number of students. The course includes the following subjects, in which the instruction is largely practical:

Clinical Medicine and Physical Diagnosis; Laryngology; Clinical Surgery; Operative Surgery; Venereal Diseases; Nervous and Mental Diseases, and Electro-Therapeutics; Gynæcology; Dermatology; Otology; Clinical and Operative Obstetrics.

The instruction extends throughout the full term, which will hereafter be seven months. Students of the University who pursue a four years' course, and who pass a satisfactory examination upon these studies of the fourth year, in addition to that upon those of the three years, will receive, in addition to the regular diploma, a certificate, appropriately signed and sealed.

PROF. CHARLES LASÈGUE.—*The Archives Générales de Médecine*, for April, is issued bordered in black, on account of the recent death of Prof. Charles Lasèque, its senior editor. It also contains an eloquent and feeling tribute to his memory, from the pen of his co-editor, Prof. S. Duplay.

A NEW WEEKLY JOURNAL, entitled *Health*, will shortly be issued in London. Its programme will include original articles, essays on health, with departments for interesting matters of the family circle, recreation, correspondence on health topics, etc.

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending April 7, 1883, indicate that remittent fever, measles, and tonsillitis have increased, and that consumption, dysentery, bronchitis, and typho-malarial fever have decreased in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported present during the week ending April 7, and since, at thirteen places, scarlet fever at nineteen places, and measles at twenty-four places.

LIGATION OF THE INNOMINATE.—MR. MITCHELL BANKS tied the innominate artery on February 28, at the Liverpool Royal Infirmary, for aneurism of the second portion of the subclavian. The common carotid was also ligated. Mr. Girdlestone's kangaroo tendons were used with strict antiseptic precautions. The patient improved rapidly, and has left the Infirmary with his aneurism much better. This is the twenty-third case in which the innominate has been ligated; twenty-one proved fatal.—*Lancet*, March 31, 1883.

MONUMENT TO BUFALINI.—On March 31, 1883, the eightieth anniversary of his death, a monument of Prof. Maurice Bufalini, the distinguished pathologist, subscribed by the whole of Italy, was unveiled at Cesena, his native city.

SANITARY COUNCIL OF THE MISSISSIPPI VALLEY.—The Council met at Jackson, Miss., on the 3d inst., delegates from the medical societies, sanitary associations, commercial bodies, and health boards of twelve States being present. A Business Committee, composed of one member from each of the States represented, was immediately formed to formulate the regular order of business of the Council. Next morning this Committee submitted a series of resolutions which were freely discussed prior to their unanimous adoption.

Provision was made for the appointment of a committee to memorialize the President of the United States on behalf of the National Board of Health, petitioning that the $100,000 epidemic fund be placed in the hands of that Board in case its use is required. In the event of the inability of the National Board to carry out the system of inspection, which it had instituted, it was decided that this work should be carried on under the supervision of representatives of the Council, the rules and regulations heretofore prescribed by the Board being adopted.

Recommendation was made that the States of the Valley make voluntary contributions to be expended by the Executive Committee of the Council, in carrying out the inspection system in case no funds are placed at the disposal of the National Board for this purpose.

The system of inspection, isolation, disinfection, and quarantine, adopted by the National Board of Health, was recommended for the guidance of the health authorities of the Valley. The resolutions as reported by the Business Committee, constituted the Citizens' Auxiliary Sanitary Association the agents of the

Council in making the inspections of freight and passengers in New Orleans, when such inspections were demanded by the local boards of health, but the representatives of that body refused a responsibility which was foreign to the purposes of the Association.

The action of the Council appears to have given satisfaction to the Louisiana delegation, and to the citizens of New Orleans, if we may form an opinion from the report of the representatives of the Citizens' Association. "Your representatives think that they have reason to be satisfied at the successful accomplishment of the much desired object of obtaining harmonious and concerted action in case of an outbreak of yellow fever in the summer of 1883; and we may say that the Louisiana delegation did contribute very materially by their advice, counsel, and discussion to this desirable result. The satisfactory result obtained was more gratifying than we had any reason to expect, after listening to discussions tainted in not a few instances by the acerbity engendered by unfriendly and most unwise criticism of a body, which if not *legally* constituted, will be found to reflect and have ample power to execute the will of an *united* people, whose calamities in the past are too deeply impressed ever to be effaced. Commerce with the valley States, should this city be declared infected, may be stopped at any moment by the action of the Sanitary Council of the Valley. You will, therefore, appreciate the anxiety felt by the delegates who represented the city of New Orleans. They may well congratulate themselves that the city government, the various commercial and medical bodies, and your Association accepted the cordial invitations given to attend the meeting of the Council and participate in its deliberations. We all felt the importance of restoring that condition of confidence, so unfortunately destroyed, which secured 'the tranquility of the Valley in the presence of danger.' The danger alluded to was the existence of forty-nine cases of yellow fever in the summer of 1879: localized by means fully described in our annual address of February, 1883. Non-attendance at the meeting of the Council would have been construed as a defiance of its authority, and a doubt of its power to control commerce within the borders of the States of the valley. Whatever views may be held by individuals as to the policy or impolicy of this or that agency through which maritime quarantine should be enforced, or inland inspections made and health certificates granted, the interest of the city of New Orleans would be best promoted by accepting the situation as one which the citizens cannot control. We may do as we please, but in the case under consideration to act in a hostile manner towards the Sanitary Council of the Mississippi Valley will, in the event of a lesser outbreak of yellow fever than that of 1879, result in a total cessation of inland commerce and travel."

Michigan State Board of Health.—The Michigan State Board of Health held a quarterly meeting at its office in Lansing, Mich., on April 11, 1883. The Secretary presented a *résumé* of the work performed by other State Boards of Health, and a review of sanitary legislation in other States. He stated that in Michigan the House of Representatives had passed a bill which was likely to become a law, practically repealing that section of the Act establishing the State Board of Health which provides that the Secretary of the State Board of Health shall be the superintendent of vital statistics. If the bill becomes a law, the vital statistics will hereafter be entirely under the control of the Secretary of State. The Secretary referred to the alarming presence of smallpox in Nashville and New Orleans, and suggested that Michigan was in danger because of the approaching time when Southern people flock to the numerous summer resorts in Northern Michigan.

The Secretary was instructed to correspond with the National and other Boards of Health, and to do all that can be done to prevent the introduction of smallpox by quarantine and inter-State inspection.

The Secretary presented an account of *Sickness caused by Eating Salted Pork.* The sickness was attended by burning in the stomach and abdominal tenderness. Some of the meat was fed to four cats. The symptoms in the cats were, expansion of the pupils, vomiting, great thirst, and tenderness of the muscles. Diarrhœa was not present. Three of the cats died, the fourth one being barely able to walk after one month. They were attacked twelve hours after eating the meat. A partial microscopical examination of some of the meat by Prof. T. J. Burrill, of Champaign, Ill., disclosed nothing within the meat to have caused the illness, but on the surface of the "lean" portions there was found a *micrococcus* enormously numerous, as well as some fungous developments of a mould-like kind sparsely present. The *micrococcus* was of a new variety, entirely distinct from that of "hog cholera," which latter was not detected in the specimen. It is not known whether the organism was on the pork when it was used for food, and it has not yet been determined whether it is now alive. Culture-experiments will be instituted to determine that point. It is quite devoid of motion and has a less dense or firm appearance than most of its congeners. It takes the ordinary aniline violet stain. Usually two are connected in a figure 8 form, rarely more. The Secretary presented statements from Mr. Love, Clerk of the Board of Health of Grand Rapids, showing successful prosecution for selling diseased meat in several cases.

In the afternoon session, Prof. R. C. Kedzie made a report of his attendance at the *Meeting of the Sanitary Council of the Mississippi Valley*, at Jackson, Miss., April 3, 1883, at which he represented the Board. He reported that the meeting was unanimous in urging the continuance of the National Board of Health, and the system of river and railroad inspections, to insure the prevention of the spread of epidemic diseases, without the obstruction of travel and commercial relations between the States, and of such surveillance of the port of New Orleans as will give to the several State and important Municipal health authorities represented in the Council prompt and reliable information of the occurrence and progress of an epidemic disease in that city. Plans for such work were discussed and adopted; and it was understood that in case of the failure of the national government to carry it on after June 2, beyond which time the National Board of Health will be unable to sustain it, unless President Arthur places the $100,000 appropriation at its disposal, it will become important and necessary for the several States endangered to supply, in some way, the money to carry on the work. Delegates from Mississippi, Arkansas, and other States, pledged certain amounts in case it proves to be necessary. (Michigan has never made an appropriation available for use in preventing the *introduction* of epidemic diseases.)

This being the annual meeting of the Board, the election of a president for the ensuing two years resulted in the election of Hon. John Avery, M.D., of Greenville.

Invitations to hold sanitary conventions at Muskegon and Ionia were accepted, the dates to be hereafter decided upon.

The Secretary was requested to prepare a memorial to the President of the United States, petitioning that he place the $100,000 appropriation in the hands of the National Board of Health.

The Board after performing routine business, adjourned to meet at Reed City, Michigan, April 26 and

27, 1883, at which time there will be a sanitary convention at that place under its auspices.

CONTAGION FROM RAGS.—The danger of contagion from rags was illustrated a short time ago in a large paper-mill in New Cathcart, Scotland. A number of the work-people were engaged in sorting and cutting rags in the usual way when four of them, in the course of a few days, were seized with smallpox. The rags were consigned from Königsburg, Germany. A form of blood-poisoning among factory people is also known in Yorkshire, which has come to be known as the "wool-sorter's disease." The germs are introduced in bales of mohair, which come from certain localities in the East, where the people are notorious for their utter disregard of all sanitary precautions and regulations. The mortality among those attacked by the "wool-sorter's disease" is said to be very high, and death ensues with a suddenness which is appalling.—*Sanitary News*, March 15, 1883.

CONTAGIOUS DISEASES AT THE LIVERPOOL QUARANTINE.—During the year 1882, according to the report of the Health officer of the port, 19,781 vessels, steam and sailing, entered the port of Liverpool, England, and of these 4,840 were specially inspected. The American vessels examined, 120 in number, were found to be the best-conditioned foreign ships which entered the port. Fifty-eight vessels brought with them a history of sickness during the voyage. Smallpox, measles, scarlet fever, cholera, remittent, typhoid and yellow fevers appeared in the list of diseases imported. The smallpox cases came from Bordeaux and Gibraltar, New York, Philadelphia, Bahia, Pernambuco, and the West Indies; measles from New York, Philadelphia, and Boston; scarlet fever from New York and Montreal; cholera from Calcutta, in the "Arethusa" and "Royal Alexandra;" remittent fever from the West Coast of Africa and Carthagena; typhoid fever from New York; and yellow fever from Carthagena, West Indies, and Pensacola, Florida.

SMALLPOX IN AFRICA.—During the past six months smallpox has been devastating the more populous settlements. Cape Town and St. Paul de Loanda suffered terribly. Recent official despatches show its extension into Northern Africa. In the city of Morocco over nine hundred persons have died of the disease in the Jewish quarter of the town during the past two months. The deaths among the Moorish population were not reported, but it is believed that the number must have been very large. At the northern capital, Fez, several cases have made their appearance, some of which terminated fatally. A few deaths have been reported from Gibraltar, Spain.

BERI-BERI.—In a recent communication to the Department of State, Consul Morey, of Ceylon, quotes some passages concerning this disease from a report of a survey of the Maldive Islands, made in the early part of this century, by the commander of the East India Company's Surveying Ship "Benares." The report states that the Lascars attribute the scourge to the Maldiva wind; that on two passages from Bengal, at different seasons of the year, many of the native sailors and two or thre Europeans were attacked with the disease, which commenced with a depression of energy, swelling of the feet and ankles, rapidly ascending to the chest, which also swelled, and then the afflicted person speedily died. Death often occurred in a few days from the commencement of the attack, but in other cases the swelling was confined to the legs for several weeks; and in these, recovery took place under the influence of nourishing food and antiscorbutics.

Mr. Morey has found from an oriental work, that strangers coming to Ceylon in very ancient times, were often attacked by a disease then called in Sanscrit, Aja-ghosta, or goat's voice fever, and that the symptoms of this ancient scourge tally exactly with those of the Maldive beri-beri. The cause of Aja-ghosta was said by the ancient writers, to be poisonous exhalations from the damp earth and improper sustenance, and it was considered an epidemic disease. Mr. Morey, who has spent much time in the study of this subject, concludes that beri-beri is an acute form of scurvy, arising from bad air and improper food; that it is likely to appear anywhere in the tropics where these conditions prevail; and that it is not at all peculiar to Ceylon, although identical with Aja-ghosta, for that disease was probably prevalent in many parts of Asia, although its presence is unchronicled for want of those historical records which exist in Ceylon. The disease only appeared on land in thickly wooded localities, where it is now unknown, owing probably to the clearing of forest and jungle, and improved drainage. Its prevalence at sea among the Lascars, he conceives to be readily understood. Most of them having been bred in the localities where the disease would be likely to prevail, would be predisposed to its attack, and when deprived of suitable food and confined when debilitated, in the filthy and ill-ventilated quarters on shipboard in those days, would promptly fall victims to its influence.

OBITUARY RECORD.—FRANZ VON RINECKER, Professor of Mental Diseases and Cutaneous and Venereal Diseases in the University of Würtzburg, has recently died at the age of seventy-two years.

—— The death of VLADESCU, Professor of Ophthalmology in the University of Bucharest, is announced.

—— The death in London, on April 16th, of WILLIAM FARR, M.D., F.R.S., D.C.L., at the age of 76, is announced. From an early age he evinced a strong taste for statistical inquiry, and in 1838 was appointed Compiler of Abstracts in the Registrar-General's Office, and while in that position organized the statistical department, of which he was superintendent for many years. He was a commissioner for taking the census in 1851 and 1861, and represented the British Government at the International Statistical Congress held at various times in the chief capitals of Europe. He was a large contributor to the Statistical Society of London and the author of several valuable papers on statistics.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 9 TO APRIL 16, 1883.

ALEXANDER, CHARLES T., *Major and Surgeon.*—To be relieved from duty at the U. S. Military Academy, West Point, New York, August 28, 1883.—*Par. 6, S. O. 82, A. G. O., April* 10, 1883.

WOLVERTON, WM. D., *Major and Surgeon.*—Granted leave of absence for four months on surgeon's certificate of disability.—*Par. 7, S. O. 85, A. G. O., April* 13, 1883.

BARTHOLF, JOHN H., *Captain and Assistant Surgeon.*—The extension of leave of absence for twenty-three days, by S. O. 37, c. s. Department of the Columbia, further extended one month.—*Par. 1, S. O. 31, Military Division of the Pacific, April* 3, 1883.

GIBSON, R. J., *Captain and Assistant Surgeon.*—Relieved from duty at Cantonment, on the Uncompahgre, Colorado, and assigned to duty at Fort Hays, Kansas.—*Par. 1, S. O. 73, Department of the Missouri, April* 7, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLII. SATURDAY, APRIL 28, 1883. No. 17.

ORIGINAL LECTURES.

ON THE TREATMENT OF NEURALGIA.

A Clinical Lecture

BY PROF. DUJARDIN-BEAUMETZ,

MEMBER OF THE ACADEMY OF MEDICINE, PHYSICIAN TO THE HOPITAL ST. ANTOINE, ETC., PARIS, FRANCE.

(*Concluded from p.* 434.)

HAVING finished symptom-medication, and considered successively anodyne, revulsive, and empirical modes of treatment, we come to our second part, or pathogenetic medication.

You remember that we referred to three principal causes the etiology, or rather the pathogeny, of neuralgia; this disease being the result of modifications affecting the integrity of the nervous system, central or peripheral, or of the blood, or finally of the circulation. Here, then, are three classes of causes which we must pass in review.

From the stand-point of the nervous system, leaving one side alterations, more or less profound, and compressions of the nerves, I desire to call your attention to two points: first, the predisposition to neuralgias in the neuropathic and hysterical; second, to inflammation of the nerve-tubes or neuritis.

Neuralgia is one of the manifestations of the nervous temperament, and it may be affirmed that every nervous person suffers more or less from it. In these cases we witness the triumph of the bromides and of hydrotherapy. Bromide of potassium (alone or associated with other bromides), cold douches, local or general, and suitable outdoor exercise are the most certain methods of cure of neuralgias due to neuropathy; electricity, and especially static electricity, is a useful adjunct.

Neuritis is one of the causes of obstinate neuralgias; it entails atrophy of the member, and trophic cutaneous disturbances. The most effective remedy for neuritis is revulsion, which has a favorable influence on both pain and inflammation. Here all the revulsive methods before alluded to are applicable, and especially active cauterizations. To counteract the trophic troubles, you should have recourse to galvanism.

Neuralgias due to circulatory modifications are of two kinds, congestive and anæmic. Congestive neuralgias are especially frequent in the arthritic, and are best treated by ergot and aconitia. It is especially in facial neuralgias of plethoric persons, with marked congestion of the face, that aconitia is effective, and this by a sort of double influence on the circulation and on sensory innervation. Marino[1] has recently proposed ergotine for these congestive neuralgias, basing his recommendation on the known effects of this drug in constricting the minute vessels and anæmiating the tissues. I have never used this drug in neuralgia, having almost always found in aconitia a heroic and certain remedy. In neuralgias from cerebral anæmia, morphia is *par excellence* the medicament. It removes pain and provokes a salutary congestion of the sensory nerve-centres, which directly antagonizes the cause of the pain. Gymnastic exercises and hydrotherapy are most excellent adjuvants in these cases.

As for the alterations of the blood, which are the point of departure of dyscrasic neuralgias, they are very numerous, and chlorosis deserves the first mention. It may be affirmed that every chlorotic girl is neuralgic, and here we have an illustration of that grand principle of Hippocrates, *sanguis moderator nervorum*. Therefore, every therapeutic means which shall augment the richness of the blood, and the proportion of its hæmoglobin, is appliable to these cases; ferruginous or arsenical medication, baths of compressed air, inhalations of oxygen, country air and exercise, hydrotherapy, gymnastics, nourishing food, all these remedial measures are indicated. I cannot too strongly urge the use of arsenic in these cases of chlorosis; in my experience, the arsenical treatment has been quite as successful as the ferruginous, if not even more so; for arsenic acts, not only as a reconstituent, but it is a direct modifier of nerve substance. Those who have had the most practical acquaintance with the use of arsenic in neuralgia are the most emphatic in its praise.

This medicament may be given in the form of Fowler's solution; dose, three to ten drops after meals. [Anstie prefers this form of administration; he finds arsenic especially useful in neuroses of the par-vagum.] It is also given in granules and in pill form. [The combination with quinine, ext. aconite, and strychnine of Dr. Gross, known as Gross' neuralgic pill, is a favorite one in the United States.][1]

Certain neuralgias are of malarial origin; here we witness the triumph of sulphate of quinine. Marrotte has given us a good description of these *febrile* neuralgias, due to marsh poison. Where there is any reason to suspect any pathogenetic influence of this kind, you should be particular to ascertain whether the neuralgic attack comes on at a fixed hour, in which event you can easily and speedily control the affection by a full dose of quinine. You can increase the effect of the quinine by combining it with aconite, giving every three hours a capsule or wafer containing one-quarter of a milligramme of crystallized nitrate of aconitia, and twenty-five centigrammes of quinine; four of these may be given each day.

The diatheses, and in particular, syphilis, arthritism, dartre, have often a marked etiological relation to neuralgia. As for the first, you must not confound the so-called "osteoscopic pains" with the neuralgic pains, which really often exist under the influence of syphilis. These cases demand the ordinary anti-syphilitic treatment.

As for neuralgias of arthritic origin, they are among the most frequent, and sciatica and gout are often one and the same thing. The means which succeed the best in the treatment of gouty and rheumatic neuralgias are baths, and in particular, sulphur baths and vapor baths; the latter are often medicated to advantage with turpentine or pine shavings. In rheumatic neuralgias, the thermal waters are often successful; those of Plombières, Bourbonne, and especially Aix-les-Bains. In these neuralgias we may employ cyanide of zinc, proposed by Luton, and especially salicylate of sodium.

[1] Marino, Ergotina per use Epidermico, nelle cure delle Neuralgia, Palermo, 1877.

[1] *Vide* Cohen on "Arsenical Treatment of Neuralgia" in *Journ. Med. de Bruxelles*, 1864. Barilla, in do., for 1863. Vanlair, *The Neuralgiæ, their Forms and Treatment, etc.*, 1882.

The dartrous neuralgias are readily amenable to the arsenical treatment.[1]

Such is a somewhat curt summary of the principal indications of the pathogenetic treatment of neuralgia. I must now briefly consider the therapeutics of certain forms of neuralgia, and for convenience of arrangement will begin with the foot and end with the head.

Plantar neuralgia is one of the most painful of neuralgias, and incapacitates the sufferer from walking or standing. It is especially gouty and rheumatic patients that are affected in this way. This neuralgia is often rebellious, lasting months and even years. You have seen a good example in our wards; I allude to a certain female, who, in consequence of rheumatism following an accouchement, has been for six months confined to her bed from plantar neuralgia. What has seemed to succeed best in her case has been the application of strong tincture of iodine, and hot sulphur foot-baths.

I shall not dwell long on sciatic neuralgia, which has been often taken as the type of neuralgia. Here the revulsive medication, carried out in all its rigor, succeeds best. Sciatica is often a neuritis, and it may almost with certainty be affirmed, when this neuralgia is obstinate, and is not due to compression of blood-vessels, viscera, etc., that it proceeds from inflammation of the nerve. I believe that this frequency of neuritis of the sciatic nerve results from proximity of that nerve to the surface, and from the modifications which it is likely to experience from external influences, and especially from atmospheric changes; there is certainly no form of rheumatic neuralgia so common.

Apropos of these stubborn sciatic neuralgias, I must remark that they are often dependent on affections of the spine, especially when they are bilateral. Essential double sciaticas are very rare, and when they occur, are generally occasioned by tabes dorsalis, or, as Worms has shown, by diabetes.[2]

Neuralgia of the uterus, bladder, testicle, and spermatic cord have frequently been observed. I know that it has been disputed whether these *visceralgias* ought to be considered true neuralgias, but it is of little consequence what we call them, they are painful affections, and prompt relief is demanded. In uterine neuralgia, cauterizations are of striking utility. You will in fact observe a certain number of females, who, apart from all organic disease of the uterus, suffer pains in that organ presenting all the distinctive characters of neuralgia. In these cases revulsive applications to the os or cervix with the Paquelin cautery, or the acid nitrate of mercury, give excellent results. Do not, however, forget that in this neuralgia of the organs contained in the pelvis, one of the best methods of administering anodynes is the suppository. [Here the morphia suppository of the U. S. P., with one-third grain extract of belladonna, will do good service.]

Ileo-lumbar neuralgia is often the cause of cruel suffering, besides being rebellious to the most energetic treatment. In fact, this affection is frequently due to profound troubles of the kidney, and particularly to renal lithiasis. You are aware that in these renal cases of persistent neuralgia it has been proposed to remove, or to open, the kidney; in a word, to perform nephrectomy or nephrotomy, as Professors Leon Le Fort and Le Dentu have done. I pass by gastralgia, hepatalgia, and the greater part of abdominal neuralgias, only referring you to what I have already said in regard to them while treating of diseases of the stomach, liver, and intestines, and I come now to intercostal neuralgia. This is a very common neuralgia, and all delicate, nervous women suffer from it more or less. Peter, in his remarkable lessons on *pains in the side*, insists that intercostal neuralgia is always limited to the left side; I do not quite agree with him in this. It is true that the far greater part of painful intercostal affections are on the left side. You will nevertheless now and then see hysterical patients whose painful sensations and whose anæsthesia are exclusively right-sided. On whichever side it may occur, this neuralgia is obstinate, and resists not only morphine injections, but also revulsive treatment. Hydrotherapy, applied in the form of douches to the painful region, seems to me one of the best means of combating this rebellious intercostal neuralgia.

I shall finish this lecture by a brief consideration of the neuralgias of the fifth nerve.

Odontalgia, I need not tell you, is one of the most common of painful affections, and every one has at some time experienced the atrocious pain of toothache. This neuralgia is often determined by alveo-periostitis, or by a carious tooth, which affects the terminal portion of the dental nerve. There exists a ready means of relief for this pain in arsenious acid, which destroys the dental pulp, a method which Tomes, Magitot, and Combe have advised. A paste is recommended (to be applied on cotton to the cavity of the tooth), consisting of two parts of white arsenic, two of morphia, one of gum tragacanth, and one of glycerine. Among the numerous measures which have been employed against odontalgia, Bouchaud has counselled electricity. His method is to place the positive pole over the diseased nerve, and the negative pole a short distance from it, and to pass a mild continued current.

A word now about facial neuralgia, properly so called. These neuralgias affect sometimes the supra-orbital nerve, sometimes the infra-orbital branches; these last are the most obstinate. As I have already told you, they often yield readily to treatment by aconitina, or to sulphate of quinine when of an intermittent character. They sometimes defy all treatment, and have been known to involve the facial nerve, as well as the fifth. Without discussing the question of recurrent neuralgia—a subject which has of late been treated in a brilliant manner by Cartaz—you all know that neuralgia is often accompanied by painful contractions, and that to this syndrome the name has been applied of epileptiform neuralgia, or tic douloureux of the face. It is the most atrociously painful affection that has ever afflicted humanity, and instances have been known where it has driven its unhappy victim to suicide.

It is in these cases that surgery steps in, with its nerve-stretching and neurectomy; here too the advantages of galvanism have been lauded. If you employ electricity, you must never exceed a certain intensity, (two or three milliampères, for instance); you must also, as Apostoli enjoins, make use of rheostats, and interpose a certain resistance to the current, to avoid the *photopsias* which are produced with each modification of the current. It is understood that the positive pole must be placed over the painful point, and as for the duration of the *sèance*, it ought to be continued till the pain disappears.

I must, before finishing, say something about migraine, which (therapeutically at least) belongs to the neuralgias. You are not ignorant of the discussions which have arisen over the pathogeny of migraine, some considering it simply a neuralgia of the tri-facial, others as a special neurosis of the same nerve, or even as a neuralgia of the brain itself, a cerebralgia, as Romberg

[1] Marrotte. "Febri-neuralgiés de l'esthime du Gosier," *Bull. Gen. de Therap.*, 1874. Abbot, "Sciatic and Facial Neuralgia Treated by Salicylic Acid and Salicylate of Sodium," *Boston Med. and Surg. Journ.*, July, 1879. E. Labbé, "Neuralgiés traités par le Salicylate de Soude," *Soc. de Therap.*, Paris, Feb. 9, 1881. Lagrelette, "De la Sciatique," *Th. de Paris*, 1869. This writer advocates strongly vapor baths and hydrotherapy in sciatica.

[2] Worms, Symmetrical Sciaticas in Diabetes, Paris, 1880.

maintains. There are still others who assert, as does Du Bois-Reymond, that the principal seat of migraine is the cervical portion of the great sympathetic. This is the view generally held in France, especially by Gubler and Jaccoud. It is, in fact, probable that migraine is not a simple neuralgia, but a complex neurosis, affecting alike the cerebrum, the trigeminal nerve, and the cervical portion of the sympathetic.[1]

Whatever its pathological nature, migraine is a very distressing affection, and you will often be consulted in reference to it. You ought always, if possible, to ascertain the first cause, and as far as this is concerned, this is what you will discover: in nine cases out of ten migraine is a diathetic affection, and for my part I have frequently observed it in hemorrhoidal, arthritic, and asthmatic subjects. Your treatment then should be directed to the arthritic diathesis, of which the migraine is an expression. At other times you will find the migraine due to causes of a different character, occasional causes to which you should address your therapeutic endeavors. These causes may be ranged in three groups; first, excess of work, and especially brain work during the night-time, and with the aid of too strong a light. Piorry referred all migraines to fatigue of the eyes; to him, migraine was only a manifestation of *irisalgia*. Second, anæmia; the megrim of chlorotics is an example, coming on whenever by any cause the organism is enfeebled. Third, congestive head-troubles, instances of which we see in the hemicranias of the gouty or arthritic.

The first class of patients are benefited by rest from mental toil, and by bromide of potassium; the second may require hydrotherapy and morphia; the third will need alkalies, intestinal derivatives, and especially aconitia.

I have finished this long exposition of the treatment of neuralgia, exposition far from complete notwithstanding its length. I believe, however, that I have furnished you the general principles which ought to guide you in your practice.

In the combat with pain your therapeutic resources will be taxed to the uttermost, and you can only fulfil your professional duty by the intelligent endeavor *always to relieve, if you cannot cure.*

THE QUESTION OF TREPHINING IN INJURIES OF THE HEAD.

By HENRY B. SANDS, M.D.,

PROFESSOR OF THE PRACTICE OF SURGERY IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK; SURGEON TO THE ROOSEVELT HOSPITAL, NEW YORK.

(*Read before the New York Surgical Society, March 27, 1883.*)

The operation of trephining the skull having been performed in my service at the Roosevelt Hospital in seven cases during the past year, I have thought that a brief account of these cases might be profitable by eliciting from the members of our Society their experience in the operation, and more especially their views in regard to the indications for its performance. For ages past no surgical procedure has been the subject of keener controversy; and the diversity of opinion which still prevails concerning it suffices to prove that the question of its value is yet unsettled, and that it is one of inherent difficulty and obscurity. Further discussion, therefore, appears to be desirable, particularly when we consider the fact that a few American surgeons have lately endeavored to extend the sphere of the operation, by reviving the obsolete practice of trephining in cases of simple fracture attended with displacement or depression, even in the absence of head-symptoms, and merely as a preventive measure.

Before proceeding to relate briefly the cases above referred to, it may be proper to state that I shall employ the term trephining in its wider sense, which includes, under this designation, the several methods by which fragments of bone are elevated or removed, whether by means of a trephine, Hey's saw, chisel, elevator, or gouge-forceps.

Out of the seven cases the operation was performed once for simple fracture with depression, four times for compound fracture with depression, and twice for epileptic and paralytic affections following an injury.

Case I.—On August 23, 1882, a boy, aged 13, was brought to the hospital in a semi-comatose state, caused by a fall from a horse just before his admission. On examination, a scalp wound was found over the left, and a hæmatoma over the right parietal bone; but no fracture was discovered. The left side of the body was partially paralyzed. Treatment: iodoform dressing to scalp wound; ice-cap to head.

Aug. 25.—Patient still comatose. Dr. Halsted, the assistant surgeon, suspecting fracture, made a crucial incision over the right parietal bone, and discovered an extensive depressed fracture of the right temporal and of both parietal bones, running upward beyond the vertex. A large piece of the temporal and several fragments of the parietal bone were elevated or removed, and on following up the line of fracture to the vertex a rent was found in the dura, through which a considerable amount of brain-substance had escaped. During the operation the superior longitudinal sinus was wounded. Bleeding was arrested by pressure, and the external wound was partially closed by suture. Consciousness did not return, and death occurred two hours after the operation.

Evidently in this case the operation was useless; and undoubtedly it would not have been undertaken if the extent of the injury had been known beforehand. The case may serve, however, to enable us to discuss the general question as to the expediency of trephining in simple depressed or comminuted fracture, accompanied or not by symptoms of compression or other cerebral injury. It is hardly necessary to remark that a fracture of the skull derives its chief importance from the concomitant or subsequent injury which is sustained by the intra-cranial contents; and just as no prudent surgeon would dream of converting a simple fracture of the leg into a compound one for the sake of obtaining an accurate adjustment of the fragments, so the plea for preventive trephining in cases of simple depressed or comminuted fracture of the cranium, without head-symptoms, is based

[1] Tissot, *Nerves and their Diseases*, t. xl., Paris, 1873. Bouillaud, *Nosographie Medicale*. Pelletan, *Coup. d. œil sur la Migraine et sur ses divers traitements*. Du Bois-Reymond, *Archiv fur Anat.*, 4th livraison, 1860, p. 461. Gubler, *Dict. des Sc. Med.*, Art "Migraine." Piorry, *Memoire sur la Migraine, Traite Med. Pratique*, t. viii. p. 73.

upon the supposition that by operating, the danger of subsequent cerebral mischief will be averted. I cannot admit the force of this argument, which seems to me to undervalue, on the one hand, the resources of nature, and, on the other hand, the risks inseparable from surgical interference. Every surgeon present has doubtless met with examples of simple depressed fracture, in which no alarming head-symptoms were present, and in which permanent recovery took place without any active treatment. Surgical literature abounds in such cases. Textor cites twelve instances of depressed fracture, verified by post-mortem examination, in seven of which the depression was complete, involving both tables, and in all of which recovery had taken place without any impairment of the cerebral functions. Similar observations have been recorded by Erichsen, Nunn, Bruns, and by many other trustworthy writers.

In cases of simple comminuted fracture, without marked depression, but with considerable displacement of the fragments, early trephining is sometimes advocated on the ground that unless the loose pieces of bone are removed by operation, they will probably become necrosed, and thereby set up fatal intra-cranial inflammation. But neither of these statements is confirmed by experience. We can rarely feel certain that the comminuted portions of bone, even though freely movable, are completely detached from their vital connections; for they may still be adherent to the pericranium. But, admitting their isolation to be complete, it is conceivable that their vitality might yet be preserved by newly formed attachments to the surrounding parts. In support of this view, I may cite a case lately published by Professor MacEwen, of Glasgow, who, having applied the trephine in a compound depressed fracture of the skull, took a piece of the inner table which had been completely detached, and laid it in the trephine-aperture. The transplanted bone caused no irritation, and the wound healed without any signs of inflammation. Nevertheless, it cannot be denied that necrosis may occur under the circumstances above mentioned, although it is comparatively rare when the fracture is simple. It must be also granted that when occurring, the suppurative action excited by the presence of the dead bone may extend to the membranes of the brain, causing fatal complications. But there are so many recorded examples of necrosis following gunshot injuries of the head, in which very large pieces of necrosed bone have been removed without the occurrence of cerebral symptoms, that preventive trephining can hardly be defended unless it can be shown to be an operation free from serious risk.

The performance of the operation in cases of simple depressed fracture, without head-symptoms, with the object of removing sharp fragments of the inner table which it is assumed may have irritated or penetrated the membranes of the brain, or perhaps the brain itself, seems to me also quite unnecessary. It is true that in severe cases of simple fracture the internal table is often very extensively injured; and Bergmann has aptly remarked that a mere inspection of museum specimens might lead one to infer that simple fractures were graver injuries than those which are compound. But clinical experience proves that these extensive osseous lesions are often recovered from without surgical interference.

On the whole, then, it would appear that the apprehensions felt by those who advocate preventive trephining in the circumstances mentioned are scarcely justified by observation. And if this fact is admitted, the propriety of performing the operation of trephining must be considered as, at least, very doubtful. If our means of diagnosis were more exact, and if we were able to predict what cases would turn out badly if left to nature, active interference would often be an obvious duty; but in the absence of such knowledge, it seems unjustifiable to subject the patient to an operation which must convert a simple into a compound fracture, with its attendant danger of suppuration in close proximity to vital parts. Although a firm believer in the excellence of antiseptic surgery, I regard the unbroken skin as a surer protection to the deeper parts than the best surgical dressing that has yet been invented; and when we remember that, occasionally, even in careful hands, accidents occur in performing the operation, such as wounding the dura mater, or perhaps the brain, or one of the larger sinuses, we have still further reason to follow the conservative method of treatment which is sanctioned by the teaching and experience of the great majority of living surgeons.

The course which should be pursued in cases of simple fracture of the cranial vault, accompanied by head-symptoms, is by no means easy to decide. The unknown quantity, vaguely expressed by the term "head-symptoms," often leaves us quite in the dark regarding the seat, nature, and extent of the traumatic lesions, so that we cannot foretell whether the operation of trephining will prove beneficial, useless, or injurious. In endeavoring, however, to arrive at a definite conclusion on this point, there are certain well-known pathological and clinical facts which may sometimes guide us. Compression of the brain, resulting alone from a fragment of depressed bone, is rarely of long duration. Often, as has been remarked, considerable depression exists without any interference with the cerebral functions; and even when the depressed bone causes symptoms of compression, these frequently disappear gradually as the cerebro-spinal fluid becomes displaced or absorbed, and the circulation in the brain is restored to its normal condition. Hence, even when we trephine successfully in cases of depression, we can not always be sure that the favorable result is due to our intervention. This point is happily stated by Dieffenbach, who records his experience in the following words: "A boy fell from the first story down upon a stone pavement, and received a fracture of the right parietal bone, of which a piece three inches in circumference was depressed several lines in depth. He lay comatose. I trephined him; he recovered, and I believed that I had saved his life by the operation. A year later he fell from the same place, and struck again upon the stone pavement, this time breaking

the left parietal bone, just as he had before broken the right one. He recovered without trephining; again I believed that I had saved his life; and I began to think that he had shown much endurance at the time when he survived the operation."

It has been clearly shown that in severe cases of simple depressed fracture, accompanied with marked and prolonged signs of compression of the brain, other lesions usually coexist, such as contusion or laceration of the brain, or hemorrhagic extravasation, which may take place between the dura and the skull, in the arachnoid cavity, in the substance of the brain, or on its surface from the vessels of the pia mater. If we except those rare instances in which the compression is due solely to an extravasation between the dura and the cranium, we shall have no reason to expect that benefit would result from the application of the trephine. So far as the brain-substance is concerned, the damage it has sustained is beyond the reach of mechanical aid; its integrity, if restored, will be slowly regained, as in cases of ordinary apoplexy, by absorption of the extravasated blood. And the same process goes on, in favorable cases, when blood is effused upon the surface of the brain. We have probably all seen examples of coma lasting for days or for weeks after head injuries, but which yet ended in recovery, due, as we may fairly presume, to the gradual disappearance, by absorption, of the extravasated blood. When we consider how large a quantity of blood is often poured out within the cranium in cases of fracture, we cannot avoid the inference that the compression which it exerts is far greater than ever occurs from any depression of bone that we should think of treating by operation. In such cases trephining would be useless, either in consequence of the depth of the extravasation, or because, being widely diffused over the surface of the brain, the effused blood would not escape through the artificial opening made in the skull. Furthermore, the operation might, in some cases, prove injurious by provoking meningitis. In other words, the very facts which have been urged as affording an indication for the employment of the trephine in cases of simple fracture may, in my judgment, be used as an argument against the propriety of the operation. I refer to the gravity of the injury and the severity of the symptoms. Where the fracture is of great extent and accompanied with severe contusion or laceration of the brain, or with copious intra-cranial hemorrhage, it is extremely doubtful whether the trephine can ever be employed with advantage, while the operation must, by increasing the mechanical injury, and by favoring the occurrence of suppuration, add not a little to the already existing danger which threatens the patient's life. Perhaps I do not fully appreciate the comparative safety which attends the performance of the operation according to modern antiseptic methods; but I believe that in this class of cases future experience will prove active interference to be of doubtful utility.

There are two conditions, however, either one of which, when present, renders imperative an immediate resort to the trephine. One of these is the case in which the fracture is of limited extent, and in which there is reason to think, from its situation, or from the occurrence of monoplegia, monospasm, or hemiplegia, that a splinter from the inner table may have penetrated the motor tract of the cerebral cortex. But, as we have seen, the fractures which are attended with such displacement of fragments of the inner table are usually of small extent, and are almost invariably compound. The other case is the one in which compression of the brain is caused by an accumulation of blood between the dura mater and the cranium. Such an accumulation may result from a wound of the larger venous sinuses, but in a large majority of instances it depends on a wound or a laceration of the middle meningeal artery. The accident is most frequently accompanied by a compound fracture; but it may be met with in cases of simple fracture, and occasionally when no fracture is present. When there exists a compound fracture, the blood usually escapes through the external wound, thus rendering the diagnosis easy; but when the fracture is simple, or when the artery alone is injured, the extravasated blood separates the dura mater from the cranium, and may be poured out in sufficient quantity to cause fatal compression of the brain. The amount of blood thus extravasated may be as much as half a pint. When the brain has not sustained severe injury, and the symptoms of concussion are but slight, the signs of the arterial lesion may be quite characteristic. After a blow has been received, usually in the temporo-parietal region, the patient, although perhaps slightly stunned, soon regains consciousness, and exhibits no marked signs of cerebral injury. But, after the lapse of a few minutes, or possibly several hours, symptoms of compression appear, and soon become very marked, the patient often dying within twenty-four hours from the time of the accident. Hemiplegia sometimes occurs before insensibility is complete; and its detection is important, for the reason that a blow upon one side of the head has been known to cause a rupture of the artery on the opposite side. The accident affords a clear and positive indication for the application of the trephine, yet there are but few recorded cases of the operation. Adding one recent case to the list compiled by Bergmann, there are one hundred well-authenticated examples of hemorrhage from the middle meningeal artery. Of these, seventeen ended in recovery; and in twelve out of this number the blood escaped through an external wound. Of the remaining five, one recovered without operation, the diagnosis being confirmed by autopsy when the patient died three years later of pneumonia. The other four recovered after operation, the blood being evacuated through the trephine opening. In one of these cases, that of Hueter, the bleeding artery was secured by a ligature.

The four cases of compound depressed fracture may be related in a few words.

Case II.—A girl, aged 14, entered the hospital February 14, 1882, having been kicked on the head by a horse shortly before admission. Compound depressed fracture of frontal bone just above superciliary ridge. Depressed portion measured

one-half inch by two inches. Patient unconscious. Trephine applied on outer side of depression by Dr. Parmley, house surgeon, and depressed bone elevated, and several loose fragments removed. Catgut drainage, salicylated cotton dressing; wound closed by sutures. Patient became conscious after operation, and had no head-symptom afterwards. Temperature never rose above 100° F. Discharged cured February 29th, fifteen days after injury.

Case III.—Male, aged 23. Entered hospital June 22, 1882. Fifteen minutes previously was kicked by a horse, the injury sustained being a compound fracture of left side of frontal bone, just above superciliary ridge. Was able to walk into hospital, and showed no signs of concussion. Right pupil dilated. A portion of bone, one inch by three-fourths of an inch, comminuted and depressed. Ether. By means of trephine, gouge-forceps, and elevator, Dr. Weed, house surgeon, removed depressed fragments, and smoothed off sharp edges of bone, leaving aperture five-eighths by one inch and one-quarter. Dura uninjured. Catgut drainage. Silk sutures. Iodoform dressing. No bad symptoms. Wound healed, and patient discharged cured July 6th, fourteen days after accident.

Case IV.—A man fell eight stories, and was brought to the hospital, comatose, October 3, 1882. Had compound fracture of right femur, compound fracture of the right parietal bone, and fracture of spine in upper dorsal region, the latter injury not being discovered until after death. Pieces of bone impinging on dura mater removed by Dr. Weed, house surgeon, leaving oval opening one inch and three-fourths in length. Patient remained comatose, and died thirty-six hours after admission.

Case V.—Man, aged 50, admitted October 22, 1882. While under influence of liquor, fell upon a stove, striking the back of his head, and sustaining a compound depressed fracture in occipital region on the left side, just above superior curved line. Depressed bone measured three-fourths by one and one-half inch. Much comminution of both tables, especially the inner. No head-symptom; no wound of dura. Operation by my assistant, Dr. King. Patient etherized. Depressed fragments removed, and edge of aperture made smooth with gouge-forceps. Catgut drainage. Wound washed out, as in previous cases, with five per cent. solution of carbolic acid, and closed with silk sutures. Iodoform dressing. Patient progressed favorably, and was discharged cured November 5, 1882, fourteen days after admission.

Of these four cases, it may be observed that the third one was evidently hopeless when admitted, and that any operation under the circumstances was inexpedient. The remaining three are familar examples of recovery after trephining in compound fractures of limited extent, accompanied with depression and comminution of the bone, but not attended with any signs of serious injury to the brain. I believe that in such cases trephining is plainly indicated, and that many lives which would otherwise be lost are saved by the operation, which, by elevating depressed fragments, by removing fragments that are loose or sharp, and by permitting thorough antiseptic irrigation of the wound, reduces to a minimum the risk of intra-cranial inflammation, so greatly to be dreaded in this class of cases. To insure success, however, the operation should be performed soon after the injury, and with strict antiseptic precautions. I recall an instance in which many years ago I unfortunately delayed the operation until the third day, in consequence of the entire absence of head-symptoms. When these occurred I trephined, but lost the patient, who, I believe, might have been saved by earlier interference. If trephining has not been performed soon after the accident, and the wound seems to be doing well, I should consider it objectionable to disturb it at a later period, unless the operation was indicated by the occurrence of decided symptoms pointing to intra-cranial mischief, as I have seen cases of recovery from compound depressed fractures in which the bone was not elevated, but I do not remember to have met with such an instance except in children, who, as is well known, bear head injuries much better than is the case with adults.

While believing that trephining is to be recommended in all cases of compound fracture in which the depression is marked, but of no great superficial extent, and in all cases of punctured fracture, where there is reason to suspect that the internal table is extensively splintered or depressed, I am strongly opposed to active interference when the fracture is of great extent, and when the depression is not limited or abrupt. It is true that these cases are usually fatal, but I am sure that nothing can be gained by the extensive operative procedure that would be involved in any attempt to remedy the displacement. Aside from those cases in which the brain has suffered irreparable damage, I think that in future many successes will be obtained by careful antiseptic treatment of the wound, such as is recommended by Lister in the management of compound fracture of the bones of the extremities. The most scrupulous cleansing of the wound, the arrest of hemorrhage, the removal of foreign bodies, loose fragments of bone, and of detached portions of brain matter, if present, followed by proper drainage and dressings, are, in my judgment, the only means, which, with our present knowledge, promise any benefit in this nearly desperate class of injuries.

In the two cases that complete my list, trephining was performed at a period remote from the date of the accident.

Case VI.—Wm. G., aged 26, entered the hospital June 26, 1882. Nine years ago was struck on the head by a piece of slate weighing one pound and a quarter; became immediately unconscious, and remained in bed several weeks; when consciousness returned, left hemiplegia was observed. This remained nearly complete for several months, after which it gradually diminished and nearly disappeared. A few weeks after injury, began to suffer from epilepsy, and has ever since been liable to frequent attacks. Left hand somewhat weak; un-

able to contract index finger. Patient lively and talkative, but mind evidently impaired. On the right side of head, near parietal eminence, is a depression of bone, about one and one-fourth inch in diameter; its right edge is one and one-half inch from median line, and its centre just in front of the Rolandic line; depth of depression at centre greater than elsewhere, and estimated to be one-fourth of an inch; scalp over depression marked by a crucial scar, the point of crossing corresponding with its deepest part

Operation, June 27th: Bone exposed by a crucial incision, and trephine applied just behind margin of depression; piece removed was five millimetres in thickness. By means of gouge-forceps, the depressed bone, as well as that adjacent to it was removed, leaving a nearly circular aperture, measuring four and one-half by five centimetres. The depressed bone was quite vascular, and was considerably thickened, being twelve millimetres in thickness at its central part. No adhesions between bone and dura; no morbid condition discovered beside those already mentioned. Wound closed by silk sutures, without drainage; iodoform dressing. Before and after operation, patient took daily ninety grains of potassium bromide. Recovery took place without a bad symptom, the temperature never exceeding 100° F. The dressing was not changed until the end of a week, when complete union was found to have taken place externally; the scalp was considerably elevated, however, by a fluid accumulation beneath it, which was probably either blood or serum; it disappeared by absorption in the course of the following week, at the end of which time the patient left the hospital, in about the same condition, as regards want of mental and muscular power, as when he was admitted.

A letter, dated March 25, 1883, has just been received from the patient's father, stating that the operation has been followed by some amelioration of his condition, the epileptic seizures being somewhat less violent, the headache less intense, and the weakness of the right hand less marked.

This case was sent to me by my friend, Prof. Seguin, who advised the operation as a last resort, medicine having failed to afford the desired relief. What permanent benefit will result from the removal of the depressed and thickened bone, it remains to be seen; yet I anticipate little, if any. It seems far more rational to ascribe the patient's symptoms to textural alterations in the cerebral convolutions resulting from the primary injury, than to assume that they were due to the slight diminution in the size of the cranial cavity, caused by the depressed and hypertrophied bone.

Twenty years ago I assisted Prof. Willard Parker in operating on an epileptic girl, who had been subject to the paroxysms since her early childhood, and who had a well-marked hypertrophy of the right parietal bone, situated near the vertex. The bone was an inch in thickness at its middle part, and projected both externally and internally, the internal projection being estimated to be three-eighths of an inch below the normal plane of the internal table of the skull. The tumor was completely removed, leaving a circular aperture which was two inches in diameter. The dura mater was healthy, and not abnormally adherent. Recovery from the operation was speedy and satisfactory; but a month later the fits returned, and six months afterward became as frequent and violent as before. In this case there was no history of injury, and therefore there was greater reason to hope that an operation would prove beneficial.

Case VII.—Margaret F., æt. 39, married (?), was sent to me by Dr. R. W. Amidon, who saw her early in November, and has furnished the following notes of the case. "Bright's disease three or four years ago (swollen feet, backache), was sick nine months. Five weeks ago struck head (left parietal region) against sharp corner, was knocked down and dazed, but not stunned; no fit at that time; no signs of fracture or concussion; thinks there has always been a lump there since.

"Two weeks after injury had a 'fit,' lost consciousness and fell. Since then, at intervals of about a week, has had short epileptic attacks, preceded by queer feeling in tongue, sensation of pins and needles in right hand, then an invasion of right hand, and loss of consciousness very short, three or four seconds. Afterwards feels weak, and sleeps. Thinks that right hand has lost strength; has headache in right fronto-parietal region; denies syphilis. On examination, right side of face weak, tongue straight when protruded, grasp of left hand nearly as strong as right (25 : 30), a doubtful limp in right leg, tenderness over site of injury, which patient indicates as over middle third of ascending parietal convolution. Slight aortic direct murmur. Ophthalmoscopic examination shows optic disk not choked. Diagnosis: traumatic epilepsy. Treatment: potassium bromide. November 13th, sent to Dr. Sands for operation."

Dec. 18.—Has been under treatment with bromide of potassium in ten grain doses, *ter in die*, for some time. Has severe headaches, and at times a piercing pain just at the point of injury; has had no convulsive attack since admission, and has been going about the hospital ward; discharged, improved.

Jan. 13, 1883.—Readmitted. Has pain on left side of head, is aphasic at times, and shows some loss of power in both arms; has fits, and during the fits says she froths at the mouth, and bites her tongue.

16th.—Last night had a severe headache, and could not sleep on account of pain.

17th.—Slight facial paralysis of right side; naso-labial fold narrowed; the tongue, in protruding, deviates to the right side.

18th.—Both pupils dilated to one-fifteenth of an inch; the left pupil contracts moderately on on exposure to light; the right less so; neither responds perfectly.

20th.—Is very stupid, and sleeps most of the time. Ordered solution of potassium bromide, one drachm every four hours.

29th.—More aphasic; has an acne-eruption over face, probably due to potassium bromide.

Feb. 1.—Examination with ophthalmoscope shows

choked optic disk on both sides; dynamometer shows left hand 30, and right hand 26. No exact diagnosis was made either by Dr. Amidon or by myself as to the character of the lesion presumed to exist; but we agreed that an explorative operation would be proper, in the hope of discovering a detached splinter of bone from inner table, a chronic abscess, or some other morbid condition admitting of relief by mechanical means.

6th.—Ether: *Operation* by Dr. Sands. The scalp being shaved, an incision was made on the left side of the head, about two inches above the ear, in a direction parallel to the zygoma; the incision was about two and one-half inches long. The largest trephine was applied nearly opposite the Rolandic line, and a button of bone removed, about one-fourth of an inch thick. Nothing was found, excepting that the dura matter was apparently thickened. The incision was extended for about one inch in a direction downward and outward, and the trephine aperture enlarged by means of gouge-forceps. Pulsation of dura absent; no fluctuation could be felt. A large hypodermic needle was thrust through the dura, in three different places, to the depth of an inch, but nothing withdrawn. In making two of the punctures, however, the needle met with considerable resistance, and the idea of a tumor was suggested. When all bleeding had stopped, wound was closed with fine catgut sutures, except at upper part, which was left open; iodoform dressing.

9th.—Patient speaks very indistinctly, and not loud enough to be heard at any distance; was reported as being delirious last night; apparently more aphasic than before operation.

10th.—Less aphasic.

11th.—Patient delirious at times. P.M., patient very noisy, and disturbs the ward. Magendie's solution, ten minims.

12th.—Patient had to be tied in bed on account of delirium. 3.30 P.M., wound dressed under spray, and found to be perfectly clean; union had taken place throughout; redressed with carbolized oil, 1–12.

13th.—Slept tolerably well last night. This morning is very delirious. Magendie's solution, ten minims, administered hypodermically.

14th.—Patient this morning was cyanotic; respiration 7; pulse 120, and strong; pupils contracted and not responsive to light. Ordered atropine sulph., gr. $\frac{1}{125}$. After taking one dose, respiration 16; took two more doses before 12 M. After this time respiration 4; 2 P.M., respiration 5; pulse 140. At 11 P.M. died. Temperature after operation did not exceed 99° until the day before death, when it suddenly rose to 103°.

Report of *autopsy* by Dr. Delafield. Body fat.

"Head: A wound upon the left side of head, which has united, though not firmly, throughout. The wound runs from about two inches above the ear forward, parallel with the zygoma. Beneath this the bone has been removed. The wound in the bone is in the left parietal bone near its lower edge. The upper margin of the squamous portion of the temporal bone has been cut through. The opening through the bone is about one and one-half inch long, three-fourths of an inch broad; the edges are clean cut; the space thus left between the scalp and the dura is filled with some reddish, partially organized clot, and there is a very little pus at its edges, and in the upper fibres of the temporal muscle. The dura beneath is adherent to the pia.

"Brain: The portion of dura adherent and just under the wound, lies over the middle of the posterior central convolution, and extends a little posterior to it. The fissure of Rolando is not touched by it, but lies a few lines in front. There seems to be no meningitis. Just beneath adherent dura, in posterior central convolution, and convolution just behind it, is a gummy tumor about one inch in diameter.

Fig. 1.

Lateral view of brain, showing the position of the tumor.

"Heart, liver, spleen, lungs, kidney, and stomach are normal.

"Fallopian tube of left side terminates in a cyst containing a fœtus."

Fig. 2.

Transverse vertical section of the left cerebral hemisphere, showing the relation of the tumor to the trephine operation.

On reviewing this interesting case in the light of the post-mortem revelations, which seem to indicate a syphilitic origin of the cerebral tumor, it is

certainly a subject of regret that the true nature of the disease escaped observation during life, as possibly it might have been controlled by specific treatment. But neither Dr. Amidon nor myself was able to obtain a syphilitic history, or to discover any existing specific lesion. Certainly the symptoms were very misleading. No convulsive seizure or other sign of cerebral trouble preceded the injury to the head, which was inflicted directly over the psycho-motor centres, and which was followed, after the lapse of a fortnight, by epileptiform attacks in which the convulsive movements were strictly limited to the upper extremity on the side of the body opposite to that where the blow was received. Assuming the morbid growth, however, to have been syphilitic, it must be a matter of conjecture whether the injury acted as an exciting cause, and determined its development, or whether the causative relation was the reverse, the injury having been due to a fall which occurred when the first epileptic fit was occasioned by the already existing gummy tumor. The case is instructive as demonstrating the value of cerebral localization in determining where the trephine should be applied. At the time of the operation the patient suffered from aphasia, impairment of vision, facial paralysis, and partial paralysis of the tongue, as well as from paresis of the right upper extremity. But as the affection of the upper limb was observed some time before the other nervous disturbances occurred, it was believed that these latter symptoms were due to secondary changes, perhaps to pressure or œdema, and that the primary cause would probably be found in the centre governing the movements of this part of the body. The post-mortem examination verified the accuracy of this conclusion, and the accompanying drawing furnished by the pathologist, Prof. Delafield, shows that the tumor occupied the centre referred to, and that it lay directly beneath the opening made by the trephine. Finally, although the autopsy disclosed no evidence of cerebral inflammation excited by the operation, the active delirium which set in toward the close of life may possibly have resulted from encephalitis; and it seems certain that death, although inevitable, was hastened by the undue effects of a dose of morphine administered with the object of relieving this distressing symptom.[1]

PRELIMINARY REPORT ON THE VENOMS OF SERPENTS.

By S. WEIR MITCHELL, M.D., and EDWARD T. REICHERT, M.D.,
of Philadelphia.

(*Read before the National Academy of Science, April 18, 1883.*)

The present report represents a part only of an elaborate study of the poisons of all our own genera of serpents, and it is hoped may include a number of foreign genera. Our researches have of late been rewarded by so remarkable a discovery in toxicology that it has been thought well to announce it here rather than to await their completion. We have therefore selected from our notes such material as seems to us of interest from its novelty.

Physical Characters.—The venoms which we have obtained in a fresh state from the rattlesnake, moccasin, and copper-head, do not differ in general appearances, and are all in the form of a slightly turbid, yellowish fluid (occasionally colorless), and varying more or less in the degree of viscidity. They have no odor, and the reaction is invariably acid.

All the venoms, whether in their dried or their natural state, are soluble in water at ordinary temperatures, save for a slight cloudiness which but slowly settles. In the dry cobra venom sent us from India, by Mr. Vincent Richards, of Calcutta, there is also a little indissoluble matter, which occurs in larger flakes, and may be due to the mode of drying the poison.

When dried they resemble ordinary egg-albumen, and when thus prepared in small quantities in a porcelain capsule, innumerable radiating lines of fracture occur which break the mass into long, needle-like pieces, closely resembling acicular crystals; indeed, the resemblance is so striking that the uninitiated are frequently deceived as to the true physical condition of the venom. When larger quantities of venom are dried, these needle-like pieces are apt to be broken up by numerous cross-fractures.

In drying, venom loses a large proportion of its weight. Unfortunately, we have not had at our disposal any fresh cobra venom, nor have we as yet made any estimate of the solid constituents of the venom of the copper-head, but in our examination of the venoms of the rattlesnake and moccasin, we found a loss of nearly seventy-five per cent.

Aqueous solutions still preserve the acid reaction, and, apparently, all the properties of the fresh venom, excepting that the intensity of the poison is somewhat diminished.

These venoms, or their solutions, can be subjected to the boiling temperature of water (except the venom of the *Crotalus adamanteus*) without a complete destruction of their poisonous power, but with a noticeable alteration of their physiological properties. In the case of the *Crotalus adamanteus*, or the *diamond-back rattlesnake*, the toxicity of the venom is destroyed at a temperature below 80° C. (176° F.). As yet we have not had the opportunity of studying the venom from the *Crotalus durissus*, or other species of rattlesnakes, but one of us (Mitchell) determined years ago that the poisoning power of the venom of the *durissus* is not destroyed at a boiling temperature. It certainly is a very curious fact that the venom of the *adamanteus* is so different from other venoms, in being destroyed at so low a temperature, and our knowledge at present is not such as to offer any satisfactory explanation.

The external symptoms caused in animals by these several venoms—cobra, rattlesnake, moccasin, or copper-head—do not differ radically, save in degree. In all alike there is some primary heart disturbance, temporarily lowered blood-pressure, fatal enfeeblement of the respiratory centres, and local

[1] For the discussion elicited by this paper see page 480.

effusion of blood with lessening or loss of its power to clot. These latter symptoms are best seen when the animal survives for some hours or a day, and then also is noticeable the breaking-down of the capillaries and the tendency to local putrescence and gangrene.

There are, however, certain symptoms which make it probable that, as our studies already indicate, we shall be enabled, after further investigation, to point out certain differences which may make it possible to discriminate any one form of poisoning from the others. Beyond a doubt, cobra venom is the most intense in its poisonous power, the venom of the copper-head next, then the moccasin and rattlesnake. Our investigations in this line are as yet far from complete, and we accordingly do not assert these facts as being final or at all conclusive.

The statement of Gautier, of Paris, that he had found an alkaloid in cobra poison resembling a ptomaine, has not received any support from what we have done in the chemistry of venoms; nor has Prof. Wolcott Gibbs been, so far, any more fortunate in finding an alkaloid in the *Crotalus* poison with which we supplied him. Our work has however resulted in the isolation of three distinct proteid bodies, of which two are soluble in distilled water, and one is not. Of the former two, one is incoagulable at a temperature of 100° C. It may be obtained by boiling venom, which throws down or destroys all the other proteids, and then filtering, or by dialysis.

The fact that this proteid remains uncoagulated by boiling and will dialyze, renders it certain that it belongs to a peculiar class of bodies which are ordinarily the result of peptic or tryptic digestion, and are known as peptones. In order to determine more definitely its character we prepared a solution of *moccasin* venom by the first process, and subjected it to a careful series of tests, designed to determine more exactly its place in the family of proteids, and with these results:

(1) Readily dialyzable.
(2) Not coagulated at a temperature of 100° C.
(3) Reaction with the xantho-proteic test (nitric acid and ammonia).
(4) Reaction with Millon's reagent (mercuric nitrate).
(5) No precipitate with weak or strong nitric acid.
(6) No precipitate with CO_2.
(7) No precipitate with ferric chloride.
(8) No precipitate with cupric sulphate.
(9) Precipitated by mercuric chloride.
(10) Precipitated by absolute alcohol.
(11) Gives a faint reddish tinge with a strong solution of potassium hydrate, and a trace of cupric sulphate.
(12) Not precipitated by strong acetic acid (glacial).
(13) Precipitated by very dilute acetic acid, precipitate being redissolved by further addition of acid.
(14) Full reaction with Adamkiewicz's test for peptones.[1]
(15) Precipitated by adding a large quantity of sodium chloride, the precipitate being redissolved on the addition of a large quantity of glacial acetic acid.
(16) Precipitated by mercuric nitrate.
(17) Precipitated by absolute alcohol, precipitate being apparently redissolved on the addition of water.
(18) Precipitated by saturation with potassium hydrate, precipitate being redissolved by the addition of nitric acid, with the formation of a decidedly yellow solution (xantho-proteic) which becomes decolorized by addition of acid.
(19) Precipitated by potassium ferrocyanide in the presence of weak acetic acid.

In a critical examination of these reactions it will be observed that while the peptone in question answers to these tests in such a positive manner as to place the matter of its nature beyond doubt, there are certain reactions which are so novel as to give this body characteristics which will distinguish it from all others of its class. These peculiarities are to be found in Nos. 13, 15, and 18. We are not aware that there is any other peptone giving such reactions by these tests.

But what is much stranger is that the peptone we have discovered is the only one as yet known to constitute a portion of a secretion, or to originate within the living body in any way except as a product of the digestion of proteids.

Some of the solution of this proteid being allowed to dry at a temperature somewhat below 100° C., it was afterwards found impossible to completely dissolve it in distilled water, the mixture remaining full of coagula, which appear to be wholly insoluble. When the coagula are filtered off, it is found that the filtrate gives all the reactions as before, although the poison in it, of which we will make further mention, appears to have entirely lost its power; nor were we able to demonstrate the existence of any toxicity in the coagula. We, therefore, do not know whether after the boiling of *moccasin* venom there remain two proteids in solution or one, but the fact of the complete loss of toxic power, under the circumstances just described, indicates that the two proteids formed in the last instance result from the breaking up of the original peptone. It seems strange, however, that, if the original body be broken up, the peptone which still remains in solution should retain the chemical peculiarities of the original substance, and answer to all the tests as we have carefully determined. The dialyzed peptone from the *Crotalus*, when dried at 40° C., entirely redissolved upon the addition of distilled water, and is poisonous, and also answers to all the above tests.

The second proteid separated by us from the original venom solutions is quite as interesting as the peptone.

We have already alluded to the fact of the occurrence of a precipitate when fresh venom or its aqueous solution is allowed to stand for some hours undisturbed. The appearance of this precipitate gives one the impression of its being an albuminous body, and this only seems the more probable since the precipitate is entirely dissolved by the addition of a small amount of sodium chloride, very weak acids, or alkalies. But in order to determine more fully the nature of this substance, we prepared an

[1] As this test is not to be found in the ordinary text-books on physiology or physiological chemistry, we will state that the test consists in first adding a little sodium chloride to the suspected mixture, then some strong acid acetic, followed by acid sulphuric. This gives a lake color turning to violet, and the top of the solution has an opalescent olive tinge.

aqueous solution of *Crotalus* venom and allowed it to stand for twenty-four hours. The supernatant liquid was decanted without disturbing the precipitate, which was then repeatedly washed with distilled water until the decanted liquid gave no reaction for albuminoids and chlorides. The precipitate thus prepared, and which, of course, is wholly insoluble in distilled water, gave the following reactions:

(1) Dissolving by the addition of a small amount of sodium chloride.
(2) *Partially* precipitated from weak solutions of sodium chloride by addition of sodium chloride to saturation.
(3) Soluble in weak solutions of magnesium sulphate, but apparently *entirely* precipitated by addition of the salt to saturation.
(4) Precipitate soluble in weak acids, and again precipitated by addition of strong nitric acid.
(5) Gave proteid reaction with xantho-proteic test.
(6) Gave proteid reaction with Millon's reagent.
(7) Coagulated in weak neutral saline solutions at a temperature of about 68.5° C.

The precipitate obtained by the addition of magnesium sulphate (3) is flaky in character, contrasting with the fine precipitate deposited by saturation with the sodium chloride, and was much more abundant.

These reactions indicate without doubt that the precipitate is a proteid belonging to the *globulins*, and that it most resembles *paraglobulin*.

We have also obtained this substance during the process of the dialytic separation of the peptone, when the globulin precipitates within the dialyzer, and it may be separated by filtration or decantation and washings. The globulin principle obtained from *moccasin* venom differs from that obtained from the *Crotalus* in that (1) by boiling it is entirely dissolved in the water, instead of being coagulated; (2) that it requires much stronger alkaline and acid solutions to dissolve it.

After the extraction of the *peptone* and *globulin* principles, there still remains in solution a third body, which becomes turbid at a temperature of about 65.5° C, and coagulates a few degrees higher, and which gives reaction with the xantho-proteic and Millon's tests for proteids, and is precipitated with weak alkalies or acids. We have not as yet been able to isolate this proteid free from contamination with the globulin and peptone principles, but judging from the fact of its perfect solubility in water, the point of coagulation and behavior with dilute alkalies and acids, it is an *albumen*. As ether does not precipitate it, it is more akin to *serum-albumen* than to egg-albumen. We are now endeavoring to obtain this principle pure by dialyzing the peptone off, and afterwards separating the globulin principle from it by filtration, when we hope to be able to study its properties with more definiteness.

The whole subject of the chemistry of proteids is as yet in such an uncertain and extremely unsatisfactory condition that the best we can do now is simply to indicate to which general class of proteids these several bodies belong, and in order to distinguish them, we propose therefore for the present to call them *venom-peptone*, *venom-globulin*, and *venom-albumen*.

Our study of the physiological properties of this *venom-peptone*, though incomplete, clearly shows that while it is poisonous, it is far from possessing all the poisonous features of venom. It is much slower in its action than venom, and the local effects produced by it are of an œdematous character, contrasting strongly with the action of the pure venom, which almost immediately causes great darkening of the tissues, due to infiltration of blood which is wholly or at least partially incoagulable. When the venom-peptone is injected into the breast muscles of a pigeon, if the animal dies within an hour or so, there is scarcely any appreciable local effect, but if the dose has been smaller, the first local effect observed is a considerable œdematous swelling in the form of an abruptly protruding lump, but without any dark discoloration. At the end of twenty-four or thirty-six hours some slight discoloration is at times observed beneath the skin, and after forty-eight hours there is a discharge from the swelling of a putrescent, muddy-looking serum. If the muscles of the side are now cut into, they will be found to be considerably congested, to be marked with greenish streaks, and to give off horrible putrefactive odors. In a pigeon, killed before the end of twenty-four hours, we found beneath the œdematous swelling a cavity about an inch in diameter, which was full of broken-down tissue, having a muddy, gangrenous appearance, and a putrefactive odor, while the surrounding muscular tissues were normal in appearance. Judging from the fact that the venom-peptone does not give rise to any darkening of the muscular tissues within a short while after injection, and, indeed, as it seems probable, not until putrefaction has set in, it seems to us likely that the darkening and congestion which ultimately occur, are to be regarded as mere secondary effects, and due to the putrefactive changes induced by the poison. The remarkable power possessed by this poison to cause putrefaction in the living tissue in so short a time is astonishing, and will exact a long and patient investigation.

These differences between the effects of the *venom-peptone* and pure venom lead us to believe that the former is not the only poisonous principle in venom, and that it is the least important in point of activity. We have been so fortunate as to find a second poison factor, and one of intense activity, in *venom-globulin*. This poison is of such virulency that one-twentieth of a grain is sufficient to kill a strong pigeon in a little over two hours, and to give rise within a few minutes after injection to the production of enormous infiltration of blood into the neighboring tissues.

In two experiments made on rabbits to determine the actions of these two principles on the blood-pressure, we found that the *venom-peptone* caused an immediate fall of blood-pressure to about one-half of the normal, after which convulsions came on accompanied by a rise of pressure to above the normal. The injection of several more doses did not affect the pressure as did the first dose—these results corresponding to what we have

observed in experiments with the fresh venom. The *venom-globulin* poison seems to be devoid of any action on the blood-pressure, except to make more prominent the so-called vaso-motor curves. We also noticed in these experiments that the *venom-globulin* gave rise to bloody extravasation in the peritoneum, such as is observed in venom poisoning, whilst the *venom-peptone* did not.

As yet we have not satisfied ourselves as to whether *venom-albumen* is a third poisonous factor, since we have been unable to isolate it in a condition in which we were satisfied as to its absolute purity, on account of our having been baffled so far in completely getting rid of the venom-globulin. The results, however, obtained from our very incomplete study of the physiological properties of the *peptone* and *globulin* principles indicate that they fully represent all the poisonous qualities of venom, the *venom-globulin* being decidedly the more poisonous of the two, and, undoubtedly, the essential poisonous element.

Up to this date, all observers have regarded the venoms as representing a single poison. We have been able to show that the venom of the *moccasin* and *C. adamanteus* contains three proteids—one analogous to peptones, and a putrefacient; one akin to globulins, and a much more fatal poison, probably attacking the respiratory centres, and destroying the power of the blood to clot; and a third resembling the albumens, and probable innocent.

Finally, we have learned that the poisons of the rattlesnake (*C. adamanteus*), copper-head (*Agkistrodon contortrix*), and moccasin (*Toxicophis piscivorus*) are capable of being destroyed by bromine, iodine, bromohydric acid (thirty-three per cent.), sodium hydrate, potassium hydrate, and, as Lacerda has shown, by potassium permanganate.

The separation of the two poisons necessitates, of course, a long and elaborate series of researches, the results of which we hope to report in future.

LABORATORY OF PHYSIOLOGY,
UNIVERSITY OF PENNSYLVANIA.

MEDICAL PROGRESS.

DANGER OF PUNCTURING OVARIAN CYSTS.—PROF. ZWEIFEL relates a case in which dangerous symptoms, indicating acute peritonitis from the passage of material from a cyst of the left ovary, followed an exploratory puncture of the second largest needle of Potain's aspirator. The symptoms—pain, vomiting, and collapse—were so marked that laparotomy was immediately performed, and a large cyst removed. He found that a portion of the contents, about the size of a walnut, had escaped into the peritoneal cavity. The patient had no bad symptoms afterward. Though this was Zweifel's fifty-fifth laparotomy, an exploratory puncture in his hands has heretofore had no evil results. He thinks, however, that the puncture should not be made, unless ovariotomy can be immediately performed if necessary.—*Centralbl. f. Gynäkol.*, February 17, 1883.

TREPHINING IN INJURY OF THE HEAD.—MR. MESSITER read a paper, before the Midland Medical Society, on trephining in injuries of the skull, giving details of five cases in which this operation had been performed at the Guest Hospital, Dudley. He thinks that trephining early in many cases of cranial injury was, with the aid of Listerism, of the utmost importance.—*British Med. Journ.*, April 7, 1883.

DANGERS OF IODOFORM DRESSINGS.—Iodoform is an excellent dressing for sluggish and fungous sores, but may be dangerous if used on large, recent wounds. König records thirty-two cases of intoxication from it, with nine deaths.—*Bull. Gén. de Thérap.*, March 30, 1883.

NEPHRECTOMY.—MR. JOHN LLOYD showed, for Mr. West, before the Midland Medical Society, a kidney which the latter had removed through a lumbar incision. The patient, a boy, æt. 15, received an abdominal injury in November last, which was followed by hæmaturia, development of a lumbar tumor, pus in the urine, and pyrexia. In December, the aspirator drew off fifty-five ounces of purulent fluid. This was repeated a week later, and followed up by a lumbar incision and the insertion of a drainage-tube. Eighty ounces of purulent ammoniacal fluid passed daily through the tube. As emaciation was rapidly progressing, nephrectomy was performed. The kidney was eight inches long, four broad, three thick, and weighed ℥xvj.—*British Medical Journal*, April 7, 1883.

UMBILICAL CANCER.—M. DEPRÉS reported to the Société de Chirurgie, Paris, the removal of a cancerous tumor of the umbilicus from a man æt. 75. While dissecting it out he found that it penetrated the peritoneal cavity at the umbilical ring, and that it was necessary to open that cavity in order to completely extirpate it. He included a portion of the epiploon in the ring, and fixed it there by sutures, in order to facilitate union. The wound was dressed without antiseptic precautions, and union took place by first intention in almost the whole extent of the wound. M. Deprés is not an adherent to Listerism, and thinks that the peritoneal cavity may be safely operated upon without such antiseptic precautions.—*L'Union Méd.*, March 29, 1883.

PARENCHYMATOUS INJECTION OF CARBOLIC ACID.—Bertels has used injections of carbolic acid in a case of cynanche sublingualis with success. SKIBNEWSKI (*Vratsch*, 1883, No. 1) has used the same treatment in two very bad cases, with excellent result. In the first case the disease had been progressing for some time, until the throat and mouth were so much affected as to seriously interfere with swallowing and speech. This was also the case, to a greater extent, in the second. In the first case thirteen injections, two per cent., were made in five days, and grs. xij of the acid used. The relief was very quick in one night, and in ten days the patient was discharged. The result in the second case was still more satisfactory. The disease had lasted four days, the tumor extended down to the clavicle, swallowing and speaking impossible, great cyanosis, tongue immovable. The injections were made in the afternoon, and the next morning the tumor was so much reduced that swallowing and speaking could be performed.—*Centralbl. f. Chirurgie*, No. 13, 1883.

TRANSPLANTATION OF OVARIAN CYSTS.—DR. EDWARD MALINS describes five cases in which ovarian cysts were transplanted to a new situation. In one the separation was not absolutely complete at the time of operation, though the transplantation was advanced. In three others the union from the place of original development was entirely severed, and a connection established with fresh structures. The process by which this was accomplished created much disturb-

ance for a time, but the cysts afterward appear to have settled down with a singular accommodation on the part of their surroundings. Of the five cases recorded, four were operated upon and recovered. In the fifth case the extent of the chronic pelvic peritonitis, due to rupture of a suppurating cyst, showed that an operation would have been useless.—*Lancet*, April 7, 1883.

Etiology of Tuberculosis.—MM. Raymond and Arthaud, in closing an elaborate paper in the *Archives Générales de Médecine*, April, 1883, give the following *résumé* of their experiments: "All the experiments of inoculation with non-tuberculous substances have absolutely given us nothing, whilst analogous trials with true tubercle have constantly produced general tuberculosis, a result which, as we think, should be attributed to the precautions which we have taken, precautions bearing on the local traumatism and on the nature of the tuberculous products, taken as fresh as possible. We have been careful to place the animals under the best hygienic conditions, and under the strictest surveillance. Experience has proved that we can render animals tuberculous almost at will; for example, the monkey. To attain this result, it is sufficient that animals should be badly nourished, subject to cold, etc. The importance of this remark should not, however, be exaggerated, for even in monkeys, as the experiments of Dieulafoy and Krishaber show, the inoculation of putrid or inert material never sets up tuberculosis if the animals are well cared for."

Preservation of Urine for Microscopic Examination.—According to Dr. Curtis, the addition of about grs. iv of chloral hydrate to ℥iij of urine will preserve it for a month, if kept at ordinary temperatures. —*L'Independente*, March 25, 1883.

Quinine in Ear Disease.—Dr. Voltolini (*Monatsschr. f. Ohrenheilk.*) says: The efficacy of quinine in these diseases does not need further demonstration; but the question now is, not so much as to the use, as its abuse in therapeutics. He warns us against the enormous doses that are frequently prescribed, which, whether given at once or at intervals, are likely to provoke grave aural and ocular troubles. The troubles which these very large doses produce on the ear, and which may result in deafness, consist anatomically in hyperæmia, principally of the labyrinth.—*Ann. des Mal. de L'Oreille, du Larynx*, March, 1883.

Cyst of the Pancreas; Operation.—Prof. Gussenbauer reports the case of a man, æt. 40, who, eight weeks previously, after a hearty meal was taken with an attack of gastricismus. He went to Prof. Pibrain's clinic, where physical examination showed a rapidly increasing tumor situated below the stomach, and which gave distinct fluctuation. Gastric and intestinal disorders supervened, with considerable emaciation. Prof. Gussenbauer, after examination, diagnosticated a retro-peritoneal tumor, though he could not define its nature; but a solid tumor being thrown out on account of the clear fluctuation, a cancerous growth on account of the constricted base, and an abscess on account of the absence of inflammatory symptoms, he was inclined to think that it was a cystic growth. On studying the literature of the subject, he found that only cysts of the pancreas and hematoma of the suprarenal capsules had been found in this situation, and with these symptoms. He also concluded that the cyst was attached to the peritoneum. The operation for its removal was performed on December 21, 1882. After opening the abdomen and reaching the cyst, it was punctured by a trocar and the contents, about four pints, removed. Chemical and microscopic examination showed that the fluid was composed of altered blood. The recovery took place without any bad symptoms, except that the man has a fistulous opening about two inches long.—*Wiener Medizin. Presse*, April 1, 1883.

Climacteric Dyspepsia.—Mr. Prangley read a paper before the Norwich Medico-Chirurgical Society on a form of dyspepsia which he termed climacteric. It occurs in women between the ages of forty and fifty. The symptoms are those of great nervousness, with pain on the top of the head, noises in the ears, hot flushes and chills, with curious sensations in the abdomen; the dyspeptic symptoms are those of precordial distress, palpitation, constipation, coated tongue, and foul breath. The treatment consists in the administration of bismuth, bicarbonate of potash, and ammonia, adding valerian if the nervous symptoms predominate, followed by quinine, strychnia, and dilute nitro-muriatic acid.—*British Med. Journ.*, April 7, 1883.

Vertebral Caries and Perforation of the Œsophagus.—Penzolat records three cases of this rare affection, in one of which the complication was recognized during life. In the first, during life the signs of pulmonary and intestinal tuberculosis were recognized. The autopsy showed caries of the fifth and sixth cervical vertebræ, with perforation of the œsophagus at the level of the fifth. Second. Compression of the cord following vertebral caries, with symptoms of paralysis toward the end of life. The autopsy showed caries of the first four dorsal vertebræ, with an opening into the œsophagus almost one-half inch long. Third. Male, æt. 53, phthisical. Caries of the first dorsal vertebræ. No symptoms of compression. The opening in the œsophagus was diagnosticated by the expulsion of a large quantity of muco-sanguinolent material, strongly contrasted with the rare purulent expectoration of the preceding days. Violent cervical pain; deglutition impossible; tumefaction of the posterior wall of the pharynx. Autopsy showed caries of the first four dorsal vertebræ, with a perforation at the situation of the first.—*L'Union Méd.*, April 3, 1883.

Hepatic and Splenic Cough.—M. Trastour calls attention to the fact that a cough due to hepatic or splenic affection may lead, on account of the concurrence of symptoms simulating phthisis, to a diagnosis of the latter disease. In eight cases with bad cough, two occurred in malarial subjects; the others, on examination, showed engorgement of the liver. The cough disappears when purgatives, saline cathartics, mineral waters, quinine, etc., are exhibited.—*Revue de Méd.*, January, 1883.

Subpectoral Abscess Opening into the Lung.—Maria G., æt. thirty-eight, entered L'Hotel-Dieu, service of M. Lacombe, on May 21, 1882. No previous disease, no syphilitic history, no previous thoracic trouble. After prolonged chilliness, she was taken with pain in the whole upper right extremity, with chilly sensations, fever, anorexia, etc. The febrile state resulted in the formation of several abscesses, first in the neck, then in the axillary region and the anterior thoracic wall. The neck was tumefied, and on the inside there was a purulent collection, which opened spontaneously in about three weeks. The inflammation caused considerable œdema of the whole limb, which persisted till death. After the abscess opened, the fever abated and the appetite returned. Then other abscesses appeared: one at the internal anterior part of the axilla, another in front of the middle sternal region. Up to this time there had been no cough. Some days after the appearance of the axillary abscess, at this time about the size of a hen's egg, an incessant cough came on; at the same time there com-

menced an abundant expectoration, which soon became purulent. The two abscesses diminished as soon as the cough appeared. On entering the hospital she was very feeble and emaciated. Of the two suppurating centres already mentioned, the external is slightly projecting, its base indurated; the internal is sunken. On pressing the skin at this point a sinuous pouch is recognized. This pressure produces a gurgling sound and a hydroaëric bruit. From this point upward toward the clavicle there is subcutaneous emphysema. When the patient coughs the pouch swells out, and the gurgling sound is recognized. There is slight pain along the line joining the two abscesses. Heart and lungs sound. No diarrhœa and no fever.

Subpectoral abscess opening into the lung was diagnosticated. There being no signs of tuberculosis, the idea of a pulmonary cavity opening outward was eliminated. The only stethoscopic signs are some subcrepitant râles at the base of the right lung. There is a constant cough, the sputa being very purulent. Next day the axillary abscess opened, and the expectoration was considerably diminished. On May 27th, the opening being insufficient, M. Peyrot made two large, deep incisions, and a third below the clavicle. Two drainage-tubes were passed between the abscess and the upper incision, and the wounds were dressed antiseptically. Though the local state remained satisfactory, the patient grew worse and died May 31st.

Autopsy twenty-four hours after death. There was a large focus of suppuration below the right pectoralis major muscle, triangular, reaching from the sternum to the axilla, from the nipple to the clavicle, which has destroyed the greater part of the pectoralis major muscle and the aponeuroses of that region. The intercostal muscles were denuded and bathed in pus. At the side of the clavicle the abscess reached to the subclavicular vessels. Behind the remains of the pectoralis minor, in the third intercostal space, was a perforation about the size of a ten-cent piece. Seen through this perforation the lung appeared perfectly sound, being maintained at this level by pleuritic adhesions. There was no preëxisting lung cavity, and no bronchial ulceration. The pus was probably absorbed as by a sponge. The other organs were healthy.—*Le Progrès Méd.*, March 24, 1883.

NAPHTHALINE DRESSING.—DR. FISCHER recommends naphthaline as an antiseptic in direct applications, in the same manner as iodoform is used. Ulcers and cancers with fetid secretion rapidly take on a good appearance. It has been largely employed for filling the cavity after extirpation of the rectum, in cancer of the vagina and os, in large wounds with sinuses, in gangrene following fresh burns, amputations, etc. In grave erysipelas (according to Fischer) following articular resections, the wound should be completely filled with naphthaline; the erysipelas quickly disappears.—*Journ. de Méd. de Paris*, March 24, 1883, from *Gaz. Méd. de Strasbourg.*

GASTROSTOMY AT ST. BARTHOLOMEW'S HOSPITAL.—MR. HOWARD MARSH reports the following case: E. C., æt. 60, entered St. Bartholomew's Hospital on April 22, 1882. During the past five months he had suffered pain, with gradually increasing dysphagia, spasmodic cough, and profuse frothy mucous expectoration, occasionally streaked with blood. No abnormality in pharynx or neck. A medium-sized œsophageal bougie could not be passed beyond about the level of the sixth cervical vertebra, and a No. 6 catheter was stopped at this point. Instruments caused violent suffocative cough, and profuse expectoration. For a few weeks he improved on a fluid diet, but soon grew worse again, with rapid loss of flesh.

The preliminary step for gastrostomy was performed on July 22d, under the carbolic spray. The abdomen was opened by an incision three inches long, commencing two inches to the left of the median line, and two inches below the edge of the costal cartilages, and passing downward and outward. The middle of the anterior or upper surface of the stomach was stitched to the abdominal wall, and the wound dressed with carbolic gauze. He was fed after the operation with enemata of milk, milk and eggs, and beef-tea and brandy. Small hypodermatics of brandy were occasionally administered. On July 30th the stomach was opened with a tenotome, by an incision just large enough to admit an India-rubber tube of the size of a No. 10 catheter. No food was introduced, as he lived well enough on enemata and whatever fluids he could swallow. On August 18th a large-sized flexible tracheotomy-tube was introduced through the incision, but there was so much difficulty in passing food through it that the former methods of feeding were continued. The patient gradually sank, however, and died September 14th.

Necropsy.—At the lower margin of the opening into the stomach, and close beneath the skin, was a nodular mass of cancer, as large as a horse-chestnut. About half a pint of brown, purulent fluid lay encysted between the cardiac end of the stomach, the splenic flexure of the colon, the omentum, and the left leaflet of the diaphragm; there was no fluid in the peritoneal cavity, and no general peritonitis. The œsophagus was infiltrated with hard cancer from the cricoid cartilage downward for about seven inches; and below this were many nodules of cancer lying in its wall as far as its juncture with the stomach. The upper seven inches was a complete cancerous tube, the walls being half an inch thick. From the upper, back part of the tube sprang a flattened mass of cancer, which had pushed the œsophagus and trachea forward. The bodies of the second and third dorsal vertebræ were partly infiltrated by the cancer.—*British Med. Journ.*, March 31, 1883.

COPPER IN CANNED VEGETABLES.—M. GALLARD publishes in a brochure the report of the committee appointed to investigate this evil, composed of MM. Wurtz, Girard, Brouardel, Chatin, Rochard, and Gallard. 1. The green color, sought for by consumers, can be given to canned vegetables only by using the salts of copper, though nothing is thereby added to their alimentary properties. 2. The quantity of copper really necessary for this color is very small, and, if this is not exceeded, is not likely to prove detrimental to the health of the consumer. 3. But if by any means this small quantity is exceeded, serious troubles are likely to result; and on this account the committee deems it advisable that the use of copper in this manner be prohibited.—*Archives Gén de Méd.*, April, 1883.

RADIO-CARPAL RESECTION.—M. OLLIER has performed this operation twenty-two times. The chances of success, he thinks, are greater if it is performed early. After operating he dresses the wound with iodoform, with a modified Lister dressing. The results are variable; the solidity of the surfaces depends largely on the age of the patient; and from an orthopædic and functional view, he has noticed that the movements of flexion are easily recovered. Extension returns more slowly: It may return when the radial and ulnar epiphyses are restored. If relapses occur, M. Ollier believes that they are due to insufficient eradication of the diseased portion of bone. In all cases, he believes that it is an operation which will preserve a useful limb, and often prolong life.—*Progrès Méd.*, April 7, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.

SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, APRIL 28, 1883.

MIGRAINE AND ITS TREATMENT.

If repeated attacks of migraine, as indicated in our last issue, may set up pathological processes in the cerebral organs, this malady deserves careful consideration. To understand its nature, to compass its cure, and thus prevent the secondary changes, are, clearly, very necessary duties. Before we can form a proper therapeutical diagnosis, we must have a true conception of its character—a knowledge of the several elements which make up the morbid complexus. Migraine is commonly regarded as a neurosis—a functional nervous disorder—affecting the fifth nerve. Such a conception is necessarily partial. It is a neurosis, and something more. As a neuropathic disorder, its seat is not limited to the fifth nerve, for the stomachal derangement with which some cases open and others close, signifies derangement of the vagus. The nucleus of the fifth and that of the vagus lie in close juxtaposition and have intimate relations. The mechanism in the production of a seizure may consist in a primary affection of the fifth, the transference of the irritation to the nucleus of the pneumogastric, or in a primary implication of the terminals of the latter in the stomach, and the transmission of this impression to the nucleus of the former. There are then two forms: a trifacial, and a pneumogastric. There are, however, two conditions of the sympathetic which may accompany either of these forms: one, a condition of vaso-motor tetanus; the other, a condition of vaso-motor paresis. Eulenburg, indeed, regards sick-headache as a disorder of the sympathetic. In that form characterized by vaso-motor constriction, the face is pale, the pupil dilated; in the other form, the face is flushed, the pupil contracted. According to Féré, whom we have already quoted, those cases are most serious in their ultimate action on the brain in which the state of the vessels is that of contraction. Persistent seizures of either form of the malady must exercise a deleterious effect on the nutrition of the brain substance ultimately. Hence the importance of judicious treatment.

The management of any case, to be successful, must be concerned with the functional condition of the organs affected. Do the attacks begin with stomachal disorder? A systematic plan of diet, in which, as a rule, the starchy, saccharine, and fatty elements of the foods are either cut off, or modified, should be inaugurated at once. Usually, there are individual peculiarities—idiosyncrasies—which must be heeded. Beside the regulation of the diet, remedies to allay the irritability of the end organs of the pneumogastric, are necessary. The results are the more satisfactory if these remedies exert that therapeutical action, formerly known as nervine tonic. First in value is arsenic, of which two drops of Fowler's solution, three times a day, should be given continuously for several months or longer. For the same reasons, oxide of silver (one grain *ter die*) is a valuable remedy, with the limitation imposed by the danger of staining the skin. Fermentative changes with or without the presence of *sarcina*, acidity, the condition of lithæmia, etc., require the sulphites, creasote, the mineral acids, rarely alkalies, according to the special derangements and complications present.

When some modification of the fifth nerve is the initial change, remedies must be addressed to it. The general state, is, as a rule, that of depression. The subjects of this disorder are apt to be excitable or "nervous," and they tend to anæmia rather than plethora, hence the utility in many cases of phosphites and phosphates, of nux vomica or strychnine, especially when an atonic dyspepsia is present; and of such nervines, so-called, as guarana, paullinia, caffeine, ammonia, etc.

As the condition of the intra-cranial vessels may play so important a part in subsequent pathological processes, it is very necessary to relieve the functional derangements of the sympathetic. Do we have to deal with the tetanic state of the vessels? Then, the remedies most useful are nitro-glycerine by the stomach, nitrite of amyl by inhalation, bromide of potassium, etc. When this symptom is sudden in onset and violent, the inhalation of amyl nitrite will be most promptly efficacious. When the vascular spasm is thus relieved, the migraine gets better. When this state occurs more slowly, nitroglycerine is preferable. This remedy has valuable

curative properties in those cases characterized by persistently high arterial tension, and hence it may be administered during the interval between the seizures as a prophylactic measure. Bromide of potassium is highly useful in the same group of cases. Full doses (half a drachm to a drachm) must be prescribed when the attempt is made to abort an impending attack—a result which may sometimes be attained. During the interval the bromide may be used to procure permanent results. The spoliative effect of this remedy may be lessened by the conjoint administration of iron, arsenic, phosphates, etc. We have known of cures effected by persistent but careful administration of the bromide of potassium.

The opposite state of the sympathetic system—paresis—must be remedied by agents acting in an opposed manner. In cases characterized by a flushed face, a bounding pulse, injected conjunctivæ, etc., the appropriate remedies are ergot, digitalis, chloride of barium, strychnine, picrotoxine, etc. An efficient combination consists of the extracts of ergot and nux vomica, with digitalis in pill, given mainly in the interval between the paroxysms. A capital remedy in this form of migraine, as Frommhold long ago demonstrated, is a mild galvanic current, applied to include the pneumogastric and cervical sympathetic. The applications should be both labile and stabile—the interruptions slow—and they should be made daily for several months.

Notwithstanding the persistency with which attacks of sick-headache re-appear, from month to month, and for many years, a hopeful view may be taken of the prognosis, if the patient will submit to the dietetic conditions, and carry out faithfully the medicinal treatment. In most cases, the best results are had from a combination of plans: by combining the diet system with the remedies for each form of nervous disturbance. Various hygienic regulations need to be enforced. Individuals with neuropathic tendencies should be subjected to all the influences of the best hygiene, and this includes not only the climatic and civic agencies, but all the factors in the personal equation.

THE MICROCOCCI OF CEREBRO-SPINAL MENINGITIS.

THE presence of micrococci in the ventricular fluid of meningitis succeeding pneumonia and wounds of the skull, was shown by Klebs and Eberth, and the former also found in the ventricular fluid of a case of acute suppurative meningitis, in a school-boy of sixteen, an enormous quantity of actively moving monads, together with numerous cells. LEYDEN (*Centralbl. für klin. Med.*, March 10th) has recently more closely studied a case of primary cerebro-spinal meningitis from this standpoint. In a case which terminated unfavorably under his observation, some of the inflammatory fluid was withdrawn through the pia mater of the lumbar portion of the spinal cord, and studied with a Hartnack immersion lens; in it were found a large number of micrococci together with some exudation cells. The cocci, were, for the most part, oval and arranged in pairs, though frequently, also, isolated, and in chains of two or three diplococci. All of these organisms presented a pretty active trembling, but not forward motion. They resemble closely the cocci of pneumonia and erysipelas, but were larger and more strikingly oval. In certain of the double forms one of the cocci was quite small, the other larger and thicker. The same organisms were also found in the tissue of the pia mater.

Leyden has no doubt that we have here to do with an organism pathogenetic of meningitis, and easily distinguishable from the ordinary decomposition bacteria, which, according to Klebs and Eberth, also appear in the cerebro-spinal fluid of meningitis late in the disease. These organisms described by Leyden, also differ from the micrococci of diphtheria and pyæmia, although in pyæmic meningitis after wounds and operations, precisely the same organisms are found as in the pus and blood of pyæmia. On the other hand, the organisms found by Eberth in the lungs and brain in cases of meningitis bear a close resemblance to those found by Klebs in the ventricular fluid, as well as in the lungs in certain cases of pneumonia.

While Leyden admits a great similarity between the micrococci of the fresh exudate of cerebro-spinal meningitis, and similar organisms of pneumonia, he considers it highly probable that they are distinct, and points out the following differences: 1. Those of meningitis are larger; 2. Their oval form is more strongly pronounced; and 3. They are thicker, with a tendency to fission. He considers that the differences between those of meningitis and pneumonia are equally as great as between those of pneumonia and erysipelas. On the other hand, the resemblance between these three forms is a very striking one. All three are oval cells united into diplo-, but occasionally into strepto-cocci, and differ essentially only in their size and more or less distinctly expressed oval form.

That in these three diseases we have to do with one and the same form of bacteria, which produces now one disease and again another, is not probable, but it is of interest to know that three diseases, which in their anatomical picture and their course show much agreement, are caused by a similar micro-parasite. Pathological anatomy has long since shown an analogy between pneumonia and meningitis with erysipelas. These agreements appear important enough to justify calling attention to the

fact that erysipelas and pneumonia are not unfrequently associated with meningitis, while cerebro-spinal meningitis, even the epidemic form, is also occasionally accompanied by pneumonia.

PERINEPHRIC ABSCESS.

Perhaps the most distinguishing feature of the present time in the study of diseases is the substitution of exact for general knowledge, of precision for vagueness. In fact, it is by means of this process that differential diagnosis has become so much more reliable than heretofore.

Perinephritic, or, as Dr. John B. Roberts justly prefers to call it, perinephric abscess is a moderately common disorder, yet the study of its anatomical relations with the differing symptoms and physical signs, when it occupies this or that region about the kidney, has been scarcely attempted heretofore. It is, therefore, a valuable contribution to our exact knowledge of such abscesses that Dr. Roberts has made in a paper in the April number of the American Journal of the Medical Sciences. He arbitrarily divides the perinephric cellulo-fatty tissue into six regions, an upper, middle and lower, anteriorly and posteriorly, and then studies the anatomical relations in each region with the probable resultant symptoms of abscess in each situation. It is an attempt to clear up the obscurities which at present surround the subject. Its conclusions must be compared and corrected by subsequent experience.

Investigations of this kind are among the most valuable means of surgical progress, and as such we welcome the present study as a real acquisition.

THE CODE CONTROVERSY.

It was strongly urged at Albany when the New Code was first presented, that the only valuable expression of opinion is that which fully represents the true sentiment of the body uttering it, but the New Code supporters then refused to listen to the appeal of Dr. Squibb and others to postpone its consideration for a year, when the opinion of the profession concerning it could be ascertained (which, as the vote this year showed, would have prevented its enactment), or, indeed, to postpone the vote even for a day, but insisted upon its passage on the very same day upon which it first saw light. Such tactics are apt to provoke imitation on the part of those who have suffered from them, and who find in that fact their justification.

The advocates of the New Code in the New York Academy of Medicine are now themselves indignant at being exposed in their turn to the methods which they found so successful last year at Albany. A good cause has nothing to fear and everything to gain from the fullest discussion, and freest expression of opinion, and before a vote on so important a subject as the Code was taken last year at the State Society, or last week at the Academy of Medicine, due notice should have been previously given of the proposed action, so that every member could have fair warning to be present and poll his vote, and thus only the real expression of professional opinion on the subject could be obtained.

The general interest in the Code controversy does not seem to diminish. The Louisiana, Kentucky, and Alabama Medical Societies have again expressed, without a dissenting voice, their adherence to the National Code. The Alabama Society goes further, and urges upon the physicians of the State to give their patronage only to those journals, and to send their students only to those medical schools which are in sympathy with the National Code.

The Bellevue Hospital Medical College appreciates the spirit which is abroad, and does not intend that the sentiments of its faculty, in reference to this subject, shall be misunderstood, and it therefore states, at the head of its announcement for the ensuing year, that "The standard of medical ethics recognized by the College is embodied in the Code of Ethics of the American Medical Association."

As a further contribution to the history of the controversy, we may mention an ingenuous proposition suggested last week by the New York *Medical Record*, that a "lasting solution of the question would be arrived at if the [American Medical] Association itself would rescind all formal codes, and simply urge the profession to establish such ethical regulations as local circumstances might render most expedient."

ANALYSIS OF QUININE PILLS.

Our enterprising contemporary *The Pharmacist and Chemist*, of Chicago, has supplemented the investigations of The Medical News into the composition of quinine pills, by a series of analyses made by Mr. C. Lewis Diehl, of Louisville, one of the most distinguished pharmaceutical chemists in the country, and in its issue for the current month it gives the results with the names of the manufacturers, and the shortage found in the product of each.

The samples of two-grain quinine pills were purchased in unbroken packages in Chicago, in January last, and hence were manufactured probably before December 16th, when the results obtained by our Commission were published. The method of analysis pursued by Mr. Diehl was practically the same as was used by The News Commission, but the results in each case gave a greater deficiency of quinine than was found in our samples, and they also showed the existence of foreign alkaloids, none of which,

according to the official tests of the *United States Pharmacopœia*, were found by our Commission.

The results, as given by *The Pharmacist and Chemist*, are as follows:

Number corresponding to analysis.	Amount in grains of quinine in each two-grain pill.	Amount in grains of foreign alkaloids.
3	1.772	0.240
1	1.722	0.244
2	1.634	0.316
10	1.618	0.304
4	1.616	0.310
6	1.548	0.388
7	1.546	0.304
5	1.512	0.266
8	1.432	0.606
9	0.940	0.690

The importance of the results of these analyses of THE MEDICAL NEWS, and of *The Pharmacist and Chemist*, can scarcely be overestimated, and they show that if the leading manufacturing pharmacists desire to retain the confidence of the profession and of the public, they must revise their working formulæ, and by constant analysis, by competent chemists, of their finished products, be able to guarantee the accuracy of the composition of the preparations which are issued from their establishments.

THE QUALIFICATIONS OF A HEALTH COMMISSIONER.

THE term of office of the present Health Commissioner of the City of New York will expire shortly, and several candidates for the position are in the field. We have received a pamphlet of sixteen pages, containing a letter addressed to the Mayor of New York by one of the applicants, who has been for several years connected with the Bureau of Vital Statistics of New York city, and his selection of testimonials and of evidence that he is a suitable person for this important position is a matter of some interest.

The first testimonial which he offers is from a Professor in the New York Medical College to the effect that the applicant had studied Spanish under his direction. The second is that he was an acting assistant surgeon in the army in 1864–65. The third is from the surgeon in charge of the Army Hospital at which he served, testifying to his professional and social excellence, and gentlemanly traits. Next he tells us that he was presented with a gold watch and pencil by one hundred and eight wounded and disabled soldiers, when he left the hospital. The resolutions accompanying this present are not given—and we miss also his certificate of regular attendance at Sunday-school, and of successful vaccination, but no doubt these could be produced if necessary.

Twelve of the sixteen pages are occupied with a list of names of prominent physicians and business firms in New York City. They do not certify to anything or make any request, but we presume that they are intended to show the extent of the candidate's visiting list.

This mode of applying for an office, by means of a printed list of testimonials and sketch of the candidate's history, has been heretofore little used in this country although it is very common abroad. It is a very convenient method, especially for those who decide as to the claims of rival candidates, such as mayors, boards of trustees, etc., all of whom will no doubt strongly prefer this plan to that of personal interviews with the candidate's friends. In the present case, the convenience of such a pamphlet to Mayor Edson and John Kelly can hardly be overestimated.

The present Health Commissioner of New York, who has filled the office for a number of years with much success is Prof. Chandler, of Columbia College. He is a candidate for reappointment, but probably very few people know this except Mayor Edson, as he has not issued any list of testimonials.

The office of Health Commissioner of the City of New York is the most important position connected with public hygiene in this country, and should be filled by the best man who can be found. Before seeing the new applicant's book of testimonials, we thought that the wisest thing that Mayor Edson could do would be to reappoint Prof. Chandler;—and we are of the same opinion still.

POISONING BY DOSIMETRIC ACONITE.

OUR readers will remember that a new medical sect has arisen whose chief claim to distinction is that they employ the alkaloids in granules. They entitle their "system" *Dosimetry* or *Dosimetric*. Dujardin-Beaumetz reports a case of poisoning by the use of dosimetric granules of aconitine. As this case is curious our readers may be interested in the details. The patient for whom the nitrate of aconitine was prescribed in gradually increasing doses, finally experienced tingling in the tongue, vomiting, intoxication, coldness of the surface, feeble pulse, and other symptoms of poisoning. The dosimetric physician was called on for an explanation when such serious symptoms were induced by his remedies. To demonstrate his own confidence in the accuracy with which the granules were prepared, and to prove their innocuousness, the dosimetric physician, then and there, took sixty drops of the prepared solution—equivalent to one-eleventh of a grain of aconitine—and in five hours he was dead. The lesson to be learned from this accident is an obvious one. Granules, unless pre-

pared with great care, may contain an unexpected quantity of the alkaloid, and when a question of strength of any given preparation is to be determined, it were better to employ for this purpose some convenient animal—the Society for the Prevention of Cruelty to the contrary notwithstanding—than to offer one's self a sacrifice to misplaced confidence.

THE FEDERAL GOVERNMENT AND LOCAL SANITATION.

The Board of Health of the City of Pensacola has entered into an agreement with the U. S. Marine-Hospital Service by which its street-cleaning, garbage removal, drainage, and sanitary inspections will be conducted under its own direction, while the payment therefor will be made by the United States Treasury Department. This is a new departure in municipal sanitary work, and health officers have developed a corresponding interest in the matter. We do not see, however, that the Treasury Department can ratify any such agreement as General Hamilton has made with Pensacola, even if the special fund appropriated by Congress had already been placed at his disposal by the President, and this we understand has not been done. It is the introduction of contagious or infectious disease from foreign countries which the law authorizes the President to assist in preventing, and it requires a considerable latitude in the construction of the law to hold that all the expenses of local sanitation from May to November may be assumed by the general Government. And why Pensacola more than any other and every other seaport on the South Atlantic and Gulf coasts? All are equally exposed to the danger of importing yellow fever, and a preference of one port over others violates the Constitution directly.

REVIEWS.

Smallpox and Smallpox Hospital of New Orleans. Outline of Quarantine and Sanitary Operations of the Board of Health of the State of Louisiana During 1882. Pamphlet, pp. 27. New Orleans, 1883.

From this pamphlet, just issued by the Board of Health of Louisiana, we gather some interesting details concerning preventive sanitary work in that city. After the epidemic of 1877, when 1099 deaths were recorded, the disease gradually subsided. In 1879 the deaths numbered 141. Next year smallpox did not appear on the mortality lists. In 1880 1 fatal case occurred; in 1881 there were 5 deaths in 22 cases, and in 1882, 415 deaths among 1093 cases, the disease being evidently on the increase on account of the accumulation of unprotected persons in the city. New Orleans has a colored population of 60,000, most of which is unvaccinated. The Board is shown to have done its duty by earnestly recommending compulsory vaccination, by providing for gratuitous vaccination (during the year 4725 persons were vaccinated, over one-half of whom were colored), by having placed a warning flag on infected premises, or removing the patient to the smallpox hospital and thereafter fumigating the vacated rooms, and by having recommended the establishment of a new smallpox hospital. The present hospital is the private property of a physician, who takes care of the patients at a contract price of $1.60 each per diem. It consists of a large garden, long uncared for, and covered with dirty rags, bits of carpet, etc., in which are three shabby-looking buildings. Two of these are intended for the contract patients, while the other is occupied by the doctor and such "pay" patients as may come to him for treatment. In the public wards the utmost variety of old wooden and iron bedsteads, mostly deprived of their springs, is presented; and the mattresses, sheets, blankets, and quilts show a deplorable state of uncleanness, misery, and poverty. There are no curtains or shades to the windows to protect the sick from the glare of day; and ventilation has been forgotten. There were understood to be three or four nurses present, but it was impossible for the sanitary inspector or the investigating committee to learn what were their duties. The food seemed to consist of beans, hominy, and potatoes, articles little suited to sustain the strength of the patients in such a prostrating disease. The kitchen was furnished with a few pans and kettles, and had an old-fashioned privy attached. The inspector concludes thus: "The hospital is conducted and managed in an outrageous manner, is a shame to the City of New Orleans, and a disgrace to any enlightened community;" while the Investigating Committee sums up in similar language: "All we can say is, that a smallpox hospital, or any other hospital or asylum, intended for the relief of suffering humanity, organized, conducted, and managed as the Luzenberg Hospital of this city, is a disgrace to any city or town of ten times less importance and wealth than New Orleans. The fundamental fault lies, we think, in the contract system, which governs this institution. We cannot approve a system under which a consideration of —— per diem per head is paid for the treatment of destitute smallpox patients by any municipal authority to the private proprietor of a lot and a few rudimentary buildings decorated with the pompous and fallacious title of hospital." Hence the Board of Health recommended the building of a smallpox hospital for the city. This recommendation was approved and $5000 appropriated, but a difficulty appears to have been encountered in the selection of a site, an injunction having been granted against its erection in the proposed locality.

The smallpox patients are brought to this Luzenberg Hospital in the ordinary charity wagons that are used daily for the removal to the Charity Hospital of all cases of disease or injury, or in cabs, or spring wagons, or, as has happened, in the street-cars. These vehicles, after disposing of their dangerous loads, are used immediately all over the city in general business.

It appears also that the efforts of the Board to warn the public of the existence of the disease by means of the yellow flag were resisted, and that of the president to prevent the tearing down of the flag was defeated in the courts of justice; since which time, however, a bill has been passed by the General Assembly providing for the punishment by fine or imprisonment of persons who remove, tear down, or destroy the flags on infected premises.

Dr. Jones, President of the Board, concludes its defence by arraigning the City Council and the courts of justice:

"Did the City Council establish the Smallpox Hospital, as recommended by the Board in March, 1882?

"Did the courts of justice sustain the Board of Health in their efforts to protect the inhabitants of Louisiana

from the most foul and disgusting and contagious of modern or ancient diseases?

"Did the City Council provide the necessary means (special ambulances) for the conveyance of smallpox patients?

"To all these questions, I answer, 'No.'

"The City Council, up to the present moment, have done nothing to relieve the situation." etc.

But the Board of Health pamphlet does not give the whole of the facts. It makes no reference to the assistence given by the Citizens' Sanitary Association. While the Board recommends that an ordinance be passed prohibiting the use of public hacks or carriages for the transport of smallpox patients, the Association quietly presents the city with a special ambulance for use in such cases; and while the Board recommends compulsory vaccination, the Association, in the absence of compulsory laws, endeavors to accomplish the vaccination of the colored people by securing the coöperation of their preachers.

MANUAL OF AUSCULTATION AND PERCUSSION. EMBRACING THE PHYSICAL DIAGNOSIS OF DISEASES OF THE LUNGS AND HEART, AND OF THORACIC ANEURISM. By AUSTIN FLINT, M.D., Professor of the Principles and Practice of Medicine and of Clinical Medicine in the Bellevue Hospital Medical College, etc. etc. Third edition, revised. Pp. xii. 242. Philadelphia: Henry C. Lea's Son & Co., 1883.

THE second edition of this practical and justly popular manual, was given to the profession in 1880. The fact that it was exhausted, and a new one called for in 1882, is ample evidence of the positive merit it possesses. It is conveniently divided into eight chapters, and the student is gradually led up from a general consideration of physical signs in health and disease, to the differential diagnosis of diseased conditions by a knowledge of these physical signs. As in his courses of practical instruction, so in this book, the author's plan is to simplify the subject as much as possible; to consider the distinguishing characteristics of different physical signs as determined by *analysis*, and as based particularly on the variations in the intensity, pitch, and quality of sounds; to impress the facts upon the student and reader, that the significance of physical signs relates to certain physical conditions, and that close study of the physical conditions in health and disease, is a *sine qua non* of success, in both diagnosis and treatment. In this edition, the author also gives the modes by which pulmonary signs may be reproduced in the lungs after removal from the body, and by artificial illustrations.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, March 27, 1883.

THE PRESIDENT, T. M. MARKOE, M.D., IN THE CHAIR.

PIROGOFF'S OPERATION.

DR. GERSTER presented a patient upon whom he had performed Pirogoff's operation. The man has suffered seven or eight years from osteitic disease involving nearly all of the tarsal bones. He had been subjected to a great variety of treatment, and finally Dr. Gerster proposed this operation, which he performed in the ordinary manner five weeks ago. The os calcis was not wired to the tibia, but union between the bones took place by first intention. The man was able to stump around the ward on the seventeenth day after the operation. There was one and one-quarter inch shortening.

DR. H. B. SANDS then read a paper on

THE QUESTION OF TREPHINING IN INJURIES OF THE HEAD.

(See page 463.)

DR. POST referred to the case of Dr. Van Sinderen, who, when a boy, was kicked on the head by a horse. A portion of the cranial bone nearly as large as the hand was removed from one side, and pulsation could be felt as in one of the cases presented by Dr. Halsted. He grew up to manhood, studied and practised medicine, and finally died of cerebral disease following the loss of a member of his family.

Dr. Post also referred to two cases of compound fracture of the cranium which he had recently seen in hospital practice. The first was that of an Italian, twelve years of age, who was injured by a fragment of stone thrown from the roof of a house, producing a depressed compound fracture. The loose fragments were removed, the depressed portion elevated, and the boy recovered perfectly.

At nearly the same time, a child fell from the third or fourth-story window and received a complicated injury. There were extensive compound fracture of the skull with depression, fracture of the thigh, etc. Dr. Post elevated the depressed portion of bone, but the shock was so great from the complicated injury that the patient died the next day.

In another instance a child fell from a moderate height, and after being a little dazed for a time, recovered its senses so as to be able to walk and to talk, but in the course of half an hour it became completely comatose. It was supposed that intra-cranial hemorrhage had occurred, and he trephined the patient, but did not find any blood at the seat of the injury. To his surprise, however, the coma passed away and the child recovered. At nearly the same time he had a case of almost precisely the same character, in which the patient recovered. He had supposed that the occurrence of coma half an hour or an hour after the receipt of the injury was pretty certain evidence of hemorrhage, but in both these cases recovery took place after trephining, and yet no hemorrhage was found.

DR. L. A. STIMSON, in reply to Dr. Sand's request for the experience of the Society with reference to the rarer methods of treatment, narrated two cases, one of compound fracture without trephining, and one of simple fracture with trephining. The first case he saw in Bellevue Hospital. A young man came on foot one morning, having received a blow upon the back of the head a little to one side of the median line, inflicted by a chisel. The wound was a linear one, the bone was penetrated, and one edge of the cut portion of the skull turned outwards. There were no head-symptoms. The man remained in the hospital for a week or ten days without symptoms. Suddenly, without any warning, severe cerebral symptoms developed and the case terminated fatally within a few hours. At the autopsy there was found an incised wound in the soft parts and in the bone, with very slight splintering of the inner table. The dura mater was not injured. There was an abscess about the size of a hickory nut in the substance of the brain, separated from the dura mater by a layer of healthy brain tissue. There was a small amount of pus and serum between the dura and the bone at the point of fracture. Death was apparently the result of the inflammatory processes in the wound, and of its insufficient drainage.

The second case was one of simple fracture treated by trephining. A young man fell from a truck and was removed to the Presbyterian Hospital in a coma-

tose condition. Dr. Stimson saw him twenty-four hours after the receipt of the injury, and the patient was still comatose. There was no wound of the scalp and only a slight puffiness on the left side of the head, which the house surgeon said was not present when the patient was admitted to the hospital. There was slight weakening of the left forearm. There were no other symptoms. On the third day after the injury he received word that the patient had had several violent general convulsions, and on visiting the hospital he found him comatose, with high fever and considerable agitation, and with very decided paralysis of the extensors of the left forearm. Dr. Stimson made an incision upon the right side of the head along the motor area, and found a long linear fracture running from behind forward, parallel to and about three inches from the median line, with slight separation, but no depression of bone. He applied a small trephine at the site of the fracture, removed a button of bone, and found a thin layer of clotted blood between it and the dura. He enlarged the opening in the bone posteriorly and the dura bulged into it, but was without pulsation. He then applied the trephine a second time about one inch anteriorly to the spot where the first opening was made, removed a button of bone, and found a clot as before, and the dura also bulged. He then introduced the needle of a hypodermic syringe, and withdrew a small amount of fluid blood, after which he nicked the dura and evacuated about a drachm of blood, which may have come, however, from a vein wounded by the needle. The patient had no more convulsions. Toward the end of the operation he seemed to be more sensitive to the handling of the wound than at first. Afterwards he developed complete facial paralysis on the right side and died on the following day. No autopsy was allowed.

While he did not think that the soft parts should be divided in cases of simple fracture, or the bone trephined without positive indications, still he did not think that this operation is a grave one, if the dura is left uninjured. It seemed to him that interference in each case must be decided by a comparison of the possible benefits with the risks of the operation. In illustration of interference based on such comparison, he mentioned a case as follows: A woman had been insane for nearly two months after falling out of a second-story window, and receiving a scalp wound behind the motor region on the right side of the head. He trephined and explored for cerebral abscess. The dura was not opened; no evidence of abscess was obtained. The patient recovered from the operation and also from her insanity, within a fortnight. As in this case, the grave mental disability seemed to justify the operation, even in the absence of probable symptoms of abscess; so in another grave case, cerebral symptoms might make it proper to change a simple fracture into a compound one, in order to remove a depressed fragment or a clot.

Dr. J. L. Little referred to a case which came under his observation a few years ago at St. Vincent Hospital. The patient fell from a height and received a slight scalp wound, which exposed the left side of the frontal bone, about one inch above the angle of the eye. Exploration showed simply bare bone, without any evidence of fracture. The patient's symptoms were those of insanity, and she became so violent that, at the end of six weeks, it was arranged to have her removed to an insane asylum. Before leaving the hospital Dr. Little thought it best to trephine, and he removed two buttons of bone and also the bridge of bone which connected the two openings, but found nothing wrong. The inner table of the skull was perfectly normal. In less than twenty-four hours there was marked improvement in the symptoms, and within two weeks after operation the patient left the hospital perfectly sane.

Dr. Little further referred to a case which he saw in consultation with Dr. Van Wyck a few years ago. The patient was a child about seven years of age, who had received a compound fracture of the right parietal bone. There being no symptoms of injury to the brain, no operation was performed. About four weeks after, when Dr. Little saw it first in consultation, the child was suffering from symptoms of compression, paralysis, dilatation of the pupil, coma, convulsions, and had had several severe rigors. The wound was granulating. Dr. Little enlarged the wound, and removed several loose pieces of bone. There was no marked depression of the fragments. The symptoms of compression evidently not depending upon depressed bone, Dr. Little ventured to puncture the dura; but finding nothing, with a delicate bistoury he then punctured the brain substance, and found an abscess some distance below the surface. About a drachm or a drachm and a half of pus made its escape. The symptoms of compression rapidly disappeared. A fungus cerebri took place, which was treated by the application of dry absorbent powders and moderate compression. The child made a perfect recovery.

Dr. Post referred to an autopsy in the case of a little girl, at which was found a depressed fracture of the skull, moderate in amount, that had not been attended with marked symptoms in the beginning. But after the lapse of several weeks, symptoms of encephalitis had come on, and had led to a fatal result. An abscess was found in the lower part of the frontal bone, on the side corresponding to the injury, and in the immediate vicinity of this depressed bone.

Dr. Sands remarked that he did not wish to be understood as being opposed to trephining in every case of simple depressed fracture. He merely wished to say that as such fractures are usually the result of a force applied over a considerable area, the lesions were liable to be extensive, and of such a character as to render trephining a useless operation; consequently, he would hesitate before converting a simple into a compound fracture. But if he believed that the fracture was limited in extent, and that mischief might be directly caused by a fragment of bone pressing upon the dura, he would not hesitate to trephine. He thought, however, that such cases were extremely rare.

The President said that his own experience accorded nearly with that of Dr. Sands. He had thought it was, as a rule, disastrous to add to an already existing fracture the complication of an external opening. In one or two instances where he had felt that the depression was abrupt and very marked, and that the symptoms were due to the depression, he had made an incision and proceeded to elevate the bone, but the cases of abrupt depressed fracture without breaking of the skin are very rare. In only one or two instances had he ventured to trephine, and he was not able to give the results. He believed that the true principle was that which Dr. Sands had announced.

Dr. Stimson referred to a case which illustrated the application of the principle advocated by Dr. Sands and Dr. Markoe. It was one of simple depressed fracture produced by a blow with a hammer. He had already reported the case to the Society. The patient was trephined and made a good recovery. There were no brain-symptoms.

The President remarked that in such a case the indications for trephining seemed to be very clear. Besides, if there were symptoms which seemed to depend especially upon the local injury, trephining should be performed.

Dr. Sands remarked that in simple fracture accompanied with deep depressions, recovery sometimes took

place without trephining. He had seen an example of this kind many years ago in the Massachusetts General Hospital.

FOREIGN BODY IN THE ŒSOPHAGUS.

DR. J. L. LITTLE presented a specimen, with the following history: The patient was admitted into St. Vincent Hospital February 28. On the night before, she accidentally broke a plate containing two false incisor teeth. She placed the broken plate in her mouth before going to bed. On awakening in the morning, the pieces became loose, and one of them slipped down into the œsophagus. On entering the hospital, the patient complained of the following symptoms: Pain between the shoulders, and just below the clavicle, on the right side; was unable to swallow liquids, the attempt giving rise to severe pain; had had slight hemorrhage from the throat. Upon examination, she complained of great pain upon pressure over the œsophagus, just above the clavicle, but no indication of a foreign body could be felt. A digital examination, and the introduction of Cusco's laryngeal forceps failed to detect any obstruction. I then introduced a probang, with a rounded, steel hook at its extremity. This was passed down about six or seven inches below the tongue, and came in contact with the foreign body. I succeeded in hooking it, and in making strong traction; but, failing to dislodge it, I unhooked it, and, after several unsuccessful attempts, I finally succeeded in dislodging it. The patient then stated that the body had slipped down further into the œsophagus. I instantly reintroduced the hook, and was fortunate to catch the body again, and to draw it up until it was in sight. The hook then slipped off, and the plate slipped down again. I then quickly introduced a pair of œsophageal forceps, and succeeded in seizing and removing it. The plate removed contained one tooth, and was of a triangular shape, measuring one and seven-eighths inch in one direction, and one and one-quarter inch in another. A slight amount of hemorrhage followed the removal. The patient was able to swallow, with some pain, immediately after, but left the hospital the next day.

DR. W. T. BULL referred to two cases in which he had removed similar foreign bodies from the œsophagus with the ordinary "coin-catcher." The first was that of a patient who, nine days before admission to the hospital, swallowed an upper plate containing two front teeth, and took nothing afterward except fluid nourishment, and that with much difficulty. He said he had lost twenty-five pounds in weight. The foreign body lodged in the œsophagus just above the entrance to the stomach. It could be pulled up to about the level of the cricoid cartilage without difficulty, and then it would disengage from the instrument and be pushed back. Dr. Bull then resorted to the following manœuvre: He introduced two coin-catchers, one beyond the plate, the other just below the cricoid cartilage, to "lie in wait." With the first, the body was drawn up till it was arrested, when the second caught it at once, and it was removed.

In the second case, the rubber plate, a smaller one, was easily caught with the coin-catcher just within the entrance to the œsophagus, and removed at the first effort.

SECONDARY HEMORRHAGE AFTER LIGATURE OF THE FEMORAL ARTERY.

DR. POST continued the history of the case which he reported four weeks previously; one in which secondary hemorrhage occurred after removal of a sarcoma of the thigh, and in which he ligated the femoral artery; subsequently, hemorrhage occurred which he thought was evidently from the distal side. Believing it to be unwise to open the wound and to ligate the vessel, he applied a compress with bandage, from the toes upwards, suspended the limb, and this method was effectual in restraining further hemorrhage. The hemorrhage had not recurred and the patient was doing well.

MEDICAL ASSOCIATION OF THE STATE OF ALABAMA.

Annual Session, held at Birmingham, April 10, 11, 12, and 13, 1883.

(Specially reported for THE MEDICAL NEWS.)

APRIL 10.—FIRST DAY.

THE Association met in annual session. The President, DR. C. D. PARKE, of Selma, in the Chair.

After the usual addresses of welcome by DR. RASSEN, President of the Birmingham Medical Society, and MR. MCLANE, Mayor of the city, and the reception of the message of the President, the Association adjourned until 8 P.M., when

THE ANNUAL ORATION

was delivered by DR. E. H. SHOLL, of Gainesville. His subject was the *Work of the Profession*, and he was attentively listened to by a large audience.

APRIL 11.—SECOND DAY.

DR. JEROME COCHRAN, of Mobile, read a paper on the *Therapeutic Uses of Quinine in Alabama*. This paper was lengthy and exhaustive, and of such a nature as not to admit of an epitome without going beyond the limits of this notice.

DR. W. H. JOHNSTON, of Selma, read an instructive paper on *Recent Improvements in Gynecology*.

DR. B. H. RIGGS, of Selma, presented an essay on *Eclampsia Gravidorum*, in which he argued that these eclamptic seizures are due to a reflex action of the nervous system.

DR. F. TIPTON, of Selma, read a paper on *Some Points in Regard to the Eyesight of Children*, and also on the *Diagnosis and Treatment of Nasal Catarrh*.

DR. CHARLES P. SANDERS, of Pleasant Ridge, presented a paper containing *Some Observations on the Principles and Practice of Medicine within the last Fifty Years*.

DR. W. W. GOLSON, of Autauga, read a paper on *Rötheln*.

DR. JEROME COCHRAN read an elaborate essay on *Alcohol, its Physiological Action upon the System, and as a Cause of Disease*.

This was followed by a lengthy and spirited discussion, which was continued through the night session to a late hour.

THE CODE OF ETHICS.

DR. R. D. WEBB, of Livingston, presented the following resolutions, which were referred to the Board of Censors, with instructions to report at the morning session of to-morrow.

Whereas, The Medical Association of Alabama views with the deepest concern and regret the action of the Medical Society of the State of New York, at Albany, in February last, in adhering to its former action in regard to the Code of Ethics; and, although this Association, at its meeting held in Mobile, in April, 1882, passed resolutions condemning the former action, yet feeling that this is a blow at the fundamental principle of all medical ethics, we deem it proper, upon the reaffirmation of this dangerous doctrine by the Medical Society of New York, that this Association again declare its views; therefore,

Resolved, That, as an Association looking to the advancement of medical science, we can but regard this action as unnecessary and unwise, and calculated to create schism in that noble body of men who have for so many centuries worked harmoniously together upon the basis of *unity of principle and community of thought.*

Resolved, That as an Association, acting through our delegates to the American Medical Association, at Cleveland, we will use every fraternal means to induce these erring brothers to return to their allegiance, to what we regard as the basis of medical ethics; and in the event of failure in this, we will use all honorable means to exclude them from a participation in the benefits and privileges arising from the medical compact, based upon this *oneness* in principle and thought, and springing, as it does, from a recognition of true scientific principles in medicine as opposed to special dogmas.

Resolved, That as the ethical relations of the profession, and the views, especially of the younger members, are greatly influenced by the tone of the medical press, we can but condemn the course of those journals which have espoused this "new code" idea, and we discourage subscriptions to such journals in this Association upon this ground, however worthy in other respects.

Resolved, That as the views and opinions of professors of colleges, whether on medicine proper, or medical ethics, are generally received as *ex cathedra* by students, and by them carried into the ranks of the profession, we can but view with distrust those medical colleges where this view of ethics is openly inculcated, and hence cannot consistently recommend such colleges to the medical students of this State.

April 12.—Third Day.

The resolutions introduced by Dr. Webb on yesterday, were reported back by the Board of Censors, with the recommendation that they pass.

They were then passed by the Association without a dissenting voice.

Dr. M. H. Jordan, who had been appointed as leader in the "*omnibus discussion*," then introduced the following subjects, accompanying each one, as introduced, by short and pertinent remarks, calculated to draw out discussion:

1. "Is the artificial production of abortion ever justifiable for the uncontrollable nausea and vomiting of pregnancy?"

2. "In abortion, should the secundines be removed by art, or left to the resources of nature?"

3. "The injudicious use of quinine. Is it hurtful in fevers attended by threatened local inflammations? Are its effects upon the hearing permanent?"

4. "The use of galvanic electricity in uterine therapeutics?"

Each of these subjects drew out spirited discussions, which occupied the greater part of the day. Want of space will not permit even an outline.

April 13.—Fourth Day.

The Board of Censors presented a lengthy and important report, which, with the review of the roll of the Societies and Councillors, and the election of officers, consumed the day.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. M. H. Jordan, of Birmingham.

Vice-Presidents.—Drs. Frank Tipton, of Selma, and S. M. Hogan, of Union Springs.

Secretary.—Dr. T. A. Mears.

Treasurer.—Dr. W. C. Jackson.

CORRESPONDENCE.

MURIATE OF QUININE.

To the Editor of The Medical News.

Sir: I have read with great interest Dr. Mixsell's article on the muriate of quinine (Quiniæ hydrochloras, U. S. P. 1880), in The Medical News of March 31, 1883. For the past two years I have been very much interested in the use of this valuable preparation, and have watched its effects very carefully in Germany, where it is a great favorite, not only in private, but in hospital practice. It is rapidly absorbed, and on this account can be given successfully in much smaller doses than the sulphate. I have found it a very valuable remedy in neuralgia, and I might say, "it works like a charm" in this painful affection. It is, in my opinion, very much to be preferred to quiniæ sulphas, in all cases. The great drawback, at present, to its general use is its great expense. I have lately imported some of the quiniæ hydrochloras through the house of Leopold Babo, of Boston, Mass., from Mark, of Darmstadt. The price is five dollars per ounce. This seems to be a very perfect preparation. It is to be hoped that an equally good one will be procurable in this country at a much lower price. I always prescribe it either in capsules or else in powders to be dissolved in a little water. Its convenience in this respect adds to its value. I should not care to have it made into pills. It has won its popularity by its rapid and faithful action, and to prescribe it in the pill form would, I fear, injure its reputation. I have repeatedly recommended it to brother practitioners, but so strong is the prejudice against all new preparations of quinine that I found very few willing to give it even a trial. The article of Dr. Mixsell's will, I trust, bring this very important remedy into more general use in this country.

Very respectfully yours,

W. Thornton Parker,
Act. Asst. Surgeon, U. S. Army.

Ft. Elliot, Texas, April 14, 1883.

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

Action of the New York Academy of Medicine on the National Code of Medical Ethics.—At the stated meeting of the New York Academy of Medicine, held on Thursday, the 19th inst., resolutions referring to the Code of Ethics were presented, which excited a very animated discussion, and were finally passed by a two-thirds vote.

The question of medical ethics has produced a division of the profession in New York City, where the contest is most animated, which is extending throughout the State. Those who sustain the "National Code" have taken the position that all of its provisions must be maintained until it is modified by the American Medical Association; while those who advocate the Code recently adopted by the New York State Medical Society, which permits regular practitioners to consult with any legally qualified practitioners, be they homœopathists, eclectics, botanics, or what not, contend that they are acting within the statutes of the State, the authority of which is superior to that of any medical organization, and especially that of the American Medical Association. It is contended by the adherents of the State Code that the County Societies must of necessity modify their by-laws, so that they shall be in accord with the Code of the State Society.

As regards the Academy of Medicine, this Society has an independent charter, and has long since adopted, as one of its by-laws, the Code of Ethics of the American Medical Association. It is the only Society in the State entitled to representation in the American Medical Association, and its delegates have already been appointed.

At the meeting of the County Medical Society, held just before the last meeting of the State Society, the President of the Academy, Dr. Fordyce Barker, to the great astonishment of many of the members of the Academy, made a long and earnest speech in favor of the "New Code." This excited a feeling of alarm among members of the Academy who are in favor of the National Code, especially as it became evident that the first Vice-President and many other officers of the Academy were also in favor of the "New Code." There was therefore, perhaps, on the part of conservative members of the Academy, some ground for the anticipation entertained by them of an attempt to commit the Academy to a support of the State Code; although the by-laws of the Academy can be modified only at a regular stated meeting, after notice given at a previous stated meeting, and then only by a vote of three-fourths of the Fellows present.

At the meeting held April 19th, there was an unusually large attendance, many who were not Fellows of the Academy being present. The registered attendance of Fellows was between ninety and one hundred. After the completion of the ordinary routine business, a short paper was read by Dr. Griswold, which was followed by the paper of the evening, by Dr. Wylie, which latter was discussed by Drs. Emmet, Lusk, and Chamberlain. Following this, under the head of new business, a set of preambles and resolutions was introduced by Dr. Austin Flint, Jr., with the following prefatory remarks:

"It is time that, in this Hall, presented by a distinguished Fellow and benefactor of the Academy, and in the presence of these portraits of former Presidents and distinguished Fellows, most of whom have passed away, resolutions should be introduced deprecating the admission of new Fellows who cannot conscientiously sign, as we have all signed, and cordially support, as we should all support, the Code of Ethics of the regular profession, which is the Code adopted by the by-laws of the Academy; I therefore move the adoption of the following:

"*Whereas*, The New York Academy of Medicine has adopted in its by-laws, as its standard of Medical Ethics, the Code of Ethics of the American Medical Association; and

"*Whereas*, Each newly elected Fellow of the Academy is required to sign its constitution and by-laws; be it

"*Resolved*, That the Committee on Admissions be, and is hereby, instructed to report to the Academy for election as resident Fellow, no physician who is known to the Committee to be in opposition to the Code of Ethics of the Academy, and who, as a consequence, cannot consistently sign the by-laws of the Academy.

"*Resolved*, That these instructions to the Committee on Admissions be continued in force until the American Medical Association shall have modified or repealed its Code of Ethics, and such modification or repeal shall have been adopted by the Academy, or until the Academy shall have modified or repealed its by-laws referring to Medical Ethics."

It was instantly moved and seconded to lay the preambles and resolutions on the table. The yeas and nays being called for, the motion to lay on the table was lost by the following count: yeas, 30; nays, 60.

The preambles and resolutions were then discussed by Drs. D. B. St. J. Roosa, A. Flint, Jr., S. S. Purple, R. F. Weir, A. H. Smith, I. B. Read, E. C. Harwood, E. L. Partridge, and C. R. Agnew. The point was raised by Dr. Agnew that the resolutions practically introduced a new requirement for resident fellowship, and were really amendments to the by-laws, requiring, as such, previous notice and a three-fourths vote. It was ruled by the President that the resolutions were not amendments to the by-laws.

Dr. Agnew stated, also, that no notice of the resolutions had been given to Fellows of the Academy, except to those supposed to be in favor of their adoption; that he became aware of the object of the meeting not before half-past seven in the evening; that the New Code party was taken by surprise, and had been entrapped, and that it was evident that the meeting had been packed. He characterized the proceedings as contrary to the laws of the State with regard to properly qualified practitioners of medicine, and as a trick worthy of the lowest form of political manœuvring.

Dr. Roosa followed in very much the same strain, and emphasized the remarks of Dr. Agnew, denouncing the measures proposed in the strongest terms. He was followed by Dr. Weir, who also opposed the resolutions as the work of a secret organization.

Dr. Flint, Jr., who spoke a second time, by permission of the Academy, defended the resolutions. He said that they simply affirmed the existing by-laws of the Academy. That, with regard to the election of new Fellows, it was evident, from circumstances which had already occurred, that instructions to the Committee on Admission were necessary. He deprecated the necessity of voting against candidates for the reason that they were opposed to the Code of Ethics of the Academy, when such candidates might simply be ignorant of the provisions of the by-laws. He stated that the Academy was the only chartered society in the State now entitled to representation in the American Medical Association, and in the medical societies of other States; that the movement to sustain the National Code should have originated in and extended from the Academy, but the conditions, with which many Fellows were familiar, had rendered this impracticable. These conditions were a powerful argument in favor of the resolutions. The profession is divided, and it is absolutely necessary that the Academy should take a position on one side or the other. He stated that the organization to sustain the National Code was not secret, but that its objects had been published in the medical journals, although not in the newspapers. In answer to the charge of "packing" the meeting, he stated that any Fellow or Fellows had a right to introduce resolutions in support of the by-laws of the Academy, and to ask those in favor of sustaining the by-laws to come to the Academy and to vote for the resolutions. He said, in conclusion, that, in his opinion, the action of the Fellows of the Academy who advocated the resolutions would compare favorably with the methods of those who adopted the so-called New Code at the State Society and at the County Society.

After the yeas and nays had been called, the preambles and resolutions were adopted by the following vote: yeas, 58; nays, 29.

It was then moved by Dr. Gouley to reconsider the vote on the preambles and resolutions, and then to postpone indefinitely the motion for reconsideration. The motion to indefinitely postpone was carried, thus preventing a reconsideration of the vote at a subsequent meeting.

Dr. Flint, Jr., then introduced the following resolution:

"*Resolved*, That the Academy hereby disavows any sympathy with the action of the State Medical Society, which has put the profession of the State, through its

State and county societies, in an attitude of opposition to to the medical profession of the rest of the United States."

This resolution was discussed in much the same tone and spirit as the first resolutions, and was carried by nearly the same vote. A motion was also made by Dr. Gouley to reconsider, and then a motion was made to indefinitely postpone the reconsideration, which last motion was carried.

The President then asked, in the interests of harmony, that some Fellow make a motion to suspend the by-laws, and to postpone all stated meetings of the Academy until the time for the first stated meeting in October. Such a motion was made and lost; whereupon the President tendered his resignation, which he afterwards withdrew.

Dr. Weir tendered his resignation as first Vice-President and Fellow of the Academy.

Drs. Agnew, Roosa, and Cushman also tendered their resignations.

At this stage of the proceedings, undue excitement was occasioned by an inquiry by Dr. Purple as to whether the Fellows who had tendered their resignations had paid their dues to the Academy, on the ground that resignations were not valid unless the Fellows resigning had paid their dues. This inquiry gave rise to hisses and other marks of disapprobation. In reply to these demonstrations, Dr. Purple said that some Fellows of the Academy seemed to regard its by-laws as a dead letter, but he wished it to be understood that some who had grown gray in the Academy, proposed that the by-laws be strictly and impartially enforced.

A motion to suspend the by-laws, and to postpone the meetings of the Academy until October, was then made and carried by the required three-fourths vote.

A motion was made to accept the resignations, but a motion to adjourn was carried amid some confusion, and the meeting adjourned at a late hour. The resignation of the President was withdrawn, and the other resignations were not acted upon, and are still in the possession of the Academy.

The excitement produced by the proceedings of the Academy is most intense. The supporters of the National Code claim that the bitter feeling manifested by their opponents is an evidence that they had hoped to "capture" the Academy. Otherwise, they say, why should not the advocates of the "New Code" rest content with their so-called victories in the State and County Societies, and allow the Fellows of the Academy of Medicine to quietly reaffirm their by-laws, which they consider essential to regularity and to recognition by the regular profession in New York and elsewhere. They ridicule the statement that a majority of the Academy is not in favor of the by-laws as they exist.

A point strongly urged by the supporters of the National Code is that they have confined their publications to the medical journals, and have had no communication with representatives of the secular press; while their adversaries have reporters at their meetings, and flood the newspapers with "interviews," which, in itself, is a violation of Medical Ethics. Whatever else may be said of the movement at the Academy, no one has charged that the proceedings were not conducted with dignity and decorum, and an entire absence of personalities even under strong provocation. The successful party at the Academy assumes to take the position that their associates are defending their rights in the profession in a strictly professional way with courage, firmness, and moderation.

NEW ORLEANS.

(From our Special Correspondent.)

Bovine Virus.—Physicians here are becoming more and more opposed to bovine virus. The use of it had become quite general, because of popular clamor for it. The unsatisfactory results may, in a measure, be due to the fact that the supply is brought from the North, and thus becomes old before it is used. We have seen many cases where the only results following its introduction were papular raspberry marks, which remain for an indefinite time, gradually fading away without pustulation. In each of two of these cases under our charge, fresh humanized virus produced a typical vesicle which ran through its regular course.

Smallpox Inoculation.—A physician here has been practising the inoculation of smallpox virus attenuated with milk. He does not state whether or not he thereby causes smallpox or varioloid. Any question respecting the results of this method of practice has long since been definitely settled. No *tertium quid* can be formed by any admixture of smallpox virus outside the human system. The practice pursued by the gentleman referred to is reported to have been followed in several instances by smallpox. In reference to the above, the Louisiana State Medical Society in convention at Shreveport adopted the following resolutions, and referred them to its standing Committee on Legislation and State Medicine for action:

Resolved, That this Society emphatically affirms its strong confidence in the efficiency of vaccinations and revaccinations as the surest and only practicable means of preventing the spread of smallpox.

Whereas, This Society is informed that it is the practice of one or more practitioners of medicine within the limits of this State to inoculate human subjects with lymph or pus taken from smallpox patients, previously mixing it with milk or cream; therefore, be it

Resolved, That the practice of inoculating smallpox by mixing any product whatever from the body of a smallpox patient with milk, cream, butter, or any fluid obtained from the cow, is productive of no modification beyond that of direct inoculation from one person to another. It does not deprive the person thus inoculated of that power to communicate the disease through the atmosphere which natural smallpox possesses, and is, therefore, dangerous to public health.

There are no State laws or city ordinances with reference to this matter.

Drainage.—The greatest rainfall that has been known here for years occurred on Saturday, April 7th. From 6.30 A.M. to 2 P.M., 6 inches of water fell, and by 10 P.M. it had amounted to 8.06 inches. From Saturday morning to Wednesday the total fall was over 10 inches. The streets were all flooded, and in the back parts of the city the water entered the houses. The fall from the Mississippi River to the Lake, a distance averaging 5 or 6 miles, is not over 15 feet from the top of the levees; the drainage of this city is thus a very serious problem. There is one advantage of this state of affairs, we can have no such thing as sewer gas, for we can have no underground sewers. The gutters are all open to the purifying action of the air, and so long as they are properly flushed with pure river water, and prevented from becoming stagnant, they do not appear to be sources of morbid contamination. Certainly they are not more likely to prove factors of disease than the underground sewerage system practised elsewhere. The New Orleans Auxiliary and Sanitary Association has done much good in this manner. It is to be hoped this plan will be continued this summer, although opposed by the State Board of Health, which, indeed, we have reason to believe, is seeking to obtain the legal abolishment of this useful association.

Leprosy.—There are four cases of leprosy in the Charity Hospital. Your correspondent has seen histories of all of them, but no tracing of the disease is

possible in any one of them. One is being treated with Chaulmoogra oil, and seems to be improving. They are to be published.

An Address in Favor of the New Code.—The advocates of the New Code held another meeting in New York City last Friday evening. In the absence of the Chairman, Dr. A. C. Post, who was detained at home by sickness, Dr. S. O. Vanderpoel, of Albany, was called to the chair. After considerable discussion, the following address was adopted:

The Association for Preventing the Re-enactment in the State of New York of the Present Code of Ethics of the American Medical Association to the Medical Profession of the State of New York:

When very many members of a learned and liberal profession come to the conclusion that the rules by which their relations to their colleagues and to the public have hitherto been regulated have been injurious to themselves and to the community, it is evidently the duty of persons having these convictions to labor for the abolition of such rules, and to state clearly the reasons why they should no longer be enforced.

The Code of Ethics of the American Medical Association which is now in force is identical with that which was in authority in the Medical Society of the State of New York, and which was abolished at the annual meeting of that Society in February, 1882. It appears from the proceedings which led to the abolition of the Code in the State of New York that there had been a gradually increasing conviction among its members that some of the provisions of the Code were arbitrary and illiberal, and that a larger liberty should be granted the members of the Society in the performance of their professional duties. After a full discussion of the subject, a vote of the Society was taken, and by a constitutional two-thirds majority the Old Code was abolished, and a new one was enacted in its place. Among those who voted for the substitution of the New Code for the old one were many who preferred the entire abolition of the special ethical code as unnecessary for the guidance of an honorable and learned profession. But the members who took this view of the subject were willing to unite with those who were less radical than themselves, in order to secure the abandonment of the most obnoxious features of the Old Code.

At the annual meeting of the Society in February, 1883, a strong effort was made by the advocates of the Old Code to undo the work of the previous year, and to re-establish in this State the Code of the American Medical Association. For this purpose, no exertions were spared to secure the election of delegates who were in favor of the proposed retrograde movement. But the efforts which were then made failed to secure the votes of even a majority of the members of the Society.

It is well known also that a strong effort is now being made, even by coercive measures, to secure in advance such a representation at the meeting of the Society in 1884 as will undo the work which was done in 1882 and 1883. Believing that such action would be injurious to the honor, dignity, and usefulness of the profession, and to the best interests of the community, we earnestly entreat the members of the profession to give the subject their serious consideration, and to use all honorable and legitimate means to prevent the re-enactment of the present Code of the American Medical Association by the Medical Society of the State of New York. It appears to us to be particularly important to preserve to each member of the profession perfect liberty to decide for himself with whom he shall consult in order to secure the best interests of the sick.

The arbitrary rules which have to so large an extent controlled the actions of medical men, and which were originally designed to defeat the efforts of irregular practitioners to gain influence with the community, have signally failed to accomplish the object in view. These rules also have not commanded the respect of intelligent men in other professions. They have been regarded as belonging to the same category as the rules by which the various trades-unions have infringed upon the individual liberty of their members, subjecting those who resisted the arbitrary action of the majority to the greatest indignities, pecuniary losses, and even personal sufferings. We call upon all fair-minded medical men to unite with us in freeing the profession from this stigma, and in giving all its members perfect liberty to practise their art in accordance with the dictates of their own consciences, and with the enlightened opinion of intelligent men who are engaged in other pursuits.

There are indications that the movement which has begun in this State is destined to extend throughout the Union, and to end in establishing a larger liberty than we have hitherto enjoyed, and in increasing the usefulness of our profession, and in giving it a more honorable position in the State and in the nation.

The American Laryngological Association.—The Fifth Annual Congress of the American Laryngological Association will be held in the City of New York, commencing on Monday, May 21, 1883, at 10 A.M., and continuing during the following two days, May 22 and 23. Sessions will be held each morning and afternoon. The following Fellows have signified their intention of presenting papers: Drs. Allen, Asch, Bosworth, Solis-Cohen, Delavan, Donaldson, Elsberg, French, Hooper, Ingals, H. A. Johnson, Knight, Langmaid, Lefferts, Lincoln, Major, Morgan, Porter, Robinson, Smith, and Wagner.

The volume of *Transactions* for 1882 will be ready for distribution within a few days.

The Wisconsin State Medical Society will hold its annual meeting on May 3d.

Dr. John S. Billings, U.S.A., was elected a member of the National Academy of Sciences, at its meeting in Washington, last week.

Jefferson Medical College.—Dr. Roberts Bartholow, Professor of Therapeutics and Materia Medica, has been elected Dean of the Faculty, in the place of Dr. Ellerslie Wallace, who has resigned on account of ill health.

The Medical College of Virginia.—The Supreme Court of Appeals of Virginia last week rendered a decision in the case of the Medical College of Virginia, upholding the old Board of Visitors, and denying the power of the Governor to create vacancies in the Board.

The Fort Wayne College of Medicine held its fourth annual commencement on March 1. Ten candidates received the degree of Doctor in Medicine. The faculty valedictory address was delivered by Prof. W. H. Gobrecht.

Harvard and the Tewksbury Inquiry.—A press dispatch states that the testimony in the Tewksbury investigation reflecting on the Harvard Medical Society will receive due attention before the investigation closes, and some interesting scenes are promised at the State House. Mr. Brown has summoned as

witnesses to testify before the Committee, President Eliot, of Harvard, Dr. Oliver Wendell Holmes, Dr. Henry J. Bigelow, Dr. David W. Cheever, Dr. H. H. A. Beach, Dr. William L. Richardson, and Dr. Charles B. Porter. All these physicians have been Demonstrators of Anatomy at the medical school, and their testimony, as well as the cross-questioning to which they will doubtless be subjected by the counsel for the prosecution, Governor Butler, will probably mark the climax of interest in the investigation.

New Medical College in Mexico.—The Mexican Government opened, in January, a free medical college in Guanajuata, the capital of the State of that name. The course will comprise six years.

A Large Verdict for Damages.—In the second trial of the suit of John Lilly against the New York Central and Hudson River Railroad, for $35,000 damages, for the loss of both legs, by accident, while employed by the defendant in the yard of the Grand Central Depot, the jury returned a verdict for that amount, which is equal to the largest sum ever recovered in a similar suit in the Brooklyn Courts.

New Medical Journal.—The Medical Society of Amiens has begun the issue of *La Gazette Médicale de Picardie*, which will be its official organ.

The Petition of the Sanitary Council of the Mississippi Valley to the President of the United States.—The Committee appointed in accordance with the resolution of the Sanitary Council of the Mississippi Valley to petition the President of the United States on behalf of the National Board of Health, and consisting of Drs. Debrell, Haskell, Dickenson, Kedzie, Speigelhalter, Jones, Speed, Carr, and Dancy, and Messrs. Fenner, Daniels, and Hadden, has drawn up and forwarded the following:

"We, the Committee appointed, sincerely petition that the fund of $100,000, in the event of the outbreak of yellow fever or other epidemic disease on the coast of our country, be placed at the disposal of the National Board of Health. That body can give confidence to the people of the Valley as to the necessary precautions and safeguards yearly demanded by the exposure of the Southern ports to the ravages of yellow fever. Their inspection stations, and the methods their officers have adopted in matters of isolation and disinfection, and in establishing quarantine only when the emergency of the occasion demands it, have earned for the National Board a degree of confidence that of itself alone is worth millions of dollars to the commerce of the country. To supplant this body, or withhold from it necessary funds to maintain inspection stations at all exposed points, will, in our humble judgment, cause the wheels of commerce to clog, bring about a feeling of distrust, and on first alarm, be it true or false, cause recourse to shot-gun policy quarantine, which can but prove destructive to the commercial interests of the Mississippi Valley, which, in a measure, affect the entire Union. With these views submitted, with full faith in the appreciation and solicitude you must feel for the public health and welfare, we herewith subscribe ourselves your most humble petitioners."

Signed by the delegates from the States of Arkansas, Illinois, Indiana, Iowa, Kentucky, Louisiana, Michigan, Mississippi, Missouri, Ohio, Tennessee, and Wisconsin.

Quarantine and Local Sanitation in Pensacola.—The following are the terms of the propositions made by Surgeon-General Hamilton of the Marine-Hospital Service, to the Board of Health of Pensacola, Florida:

"The Treasury Department will assume charge of the Quarantine Station of this port, and manage it without any expense to the city of Pensacola. It will conduct it under its own regulations as at present existing, and such additional ones as experience may demonstrate the necessity of, and in harmony with such suggestions as may be agreed upon by the Board of Health.

"As the representative of that department, I will have prepared instructions relative to the mode of fumigation and disinfection of vessels, discharge of ballast, and the inspection and general sanitary condition of all vessels entering the port. In these matters the department must use its own methods, without, however, interfering with the State and local laws, which it has no desire to conflict with.

"Aid will be extended to the Board of Health of Pensacola, in order to effect and maintain the thorough sanitation of the city. First: in the payment of bills for the removal of garbage during the months of May, June, July, August, September, and October. The garbage shall be systematically collected and removed from every house and building or enclosure under a contract made by the Board of Health, the contractors to give bonds satisfactory to the Board for the faithful performance of the work and providing for liquidated damages in case of failure. The bills for the work done under these contracts to be certified by the acting Assistant Surgeon of the Marine-Hospital Service at this station, and the president or secretary of the Board of Health. Contracts to be made for temporary drainage, and for the cleaning up of the principal streets. The drains to be opened, and gutters made under the direction of the City Engineer, and approved by the Board of Health. The contract to provide that the work shall be commenced within the earliest practicable time, and completed within thirty days from signing, otherwise the contractors to be subject to a stipulated demurrage in case of default. The work to be paid for under like restrictions, as that under other contracts.

"Two sanitary policemen are to be appointed for the season, and four temporary inspectors to be employed for the period of twenty days.

"All requisitions of the Board of Health to be forwarded through the representative of the Marine-Hospital Service at this station. Material for disinfection and fumigation will be furnished upon requisitions for the disinfection of the premises of such persons as are unable to provide or pay for themselves: none of this material to be furnished those who are able to pay for the same."

A Word for the Doctors.—Our clever contemporary *Punch* is always ready to wield its influence on behalf of science and humanity. In its issue of the 14th inst., it speaks as follows of the discussion a few days before in Parliament on the new Anti-Vivisection Bill.

"The Vivisection Abolition Bill was talked out the other day, and, as we do not wish to see the progress of medical science checked, we cannot regret that the proposal was lost. The whole question lies in a nutshell. Vivisection, as the law stands, can only be practised under very stringent regulations, and the authority of a license granted by the Home Office, which, in very rare cases, allows experiments to be made without anæsthetics. Only one per cent. of the investigations made equals the pain of an ordinary surgical operation, and what does the world owe to vivisection? The discovery of the circulation of the blood, the antiseptic surgery of the present day, the famous operation by which Mr. Spencer Wells and others have saved the lives of many hundred women;

all these, and a thousand other benefits we owe to the experiments which it is now proposed to abolish. As Mr. Cartwright said during the debate—we prefer to quote him instead of a medical man like Dr. Playfair—'Professor Lister's discoveries had revolutionized surgical science, and it was said he had reduced the mortality of man by seven or eight per cent., and yet on account of the restrictions surrounding the provisions of the present Act, he had been obliged to go abroad in order to prosecute his invaluable researches. In the Lamson case the clinching evidence which brought about a conviction, was derived from an experiment on a living animal. . . . . If this bill were passed into law, experiments would be made on human frames, and in the rudest form. In the nineteenth century the honorable and learned member asked them to prohibit investigation, to annihilate inquiry, and to say science was a thing that must be curbed.'

"No cases of cruelty under the existing Acts can be cited as occurring in this country, all the horrors of which we read, taking place in Continental cities where there are no restrictions. As Sir William Harcourt said, the question is "Whether man as the superior animal has a right to use animals for his benefit?" Of course that can only be answered in one way, but the anti-vivisectionists rush off into shameless abuse of a noble profession, and do their cause no good by it. Sir William Harcourt well summed up the debate when he said:

"They must bring a little common sense to bear on this question. They must look at it in the light of experience, and he ventured to say that true humanity was on the side of those eminent men, many of whom were among the most tender-hearted members of society. He was satisfied that, under the administration of the existing law, very little pain was inflicted, and that what pain was inflicted was under such securities and guarantees that it was not only in the course of experiment, but was abundantly justified."

"*Mr. Punch* yields to no one in his detestation of cruelty. But crimes must not remain undiscovered, our children must not die of zymotic diseases, and our wives and sisters perish for the want of the skill and the knowledge that have been obtained by humane operators from vivisection—conducted, be it remembered, in ninety-nine cases out of a hundred with the administration of anæsthetics."

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending April 14, 1883, indicate that inflammation of the brain, diarrhœa, tonsillitis, pneumonia, and whooping-cough have increased; that influenza has considerably decreased; and consumption and measles have decreased in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported present during the week ending April 14, and since, at nine places, scarlet fever at eighteen places, and measles at twenty-three places.

One case of measles came with immigrants arriving at Port Huron, April 12.

THE PLAGUE IN PERSIA.—Dispatches from Constantinople and Smyrna indicate that a contagious disease has been prevailing during February and March in a group of Kurdisch villages actually situated on Persian territory, but in close vicinity to the Turkish town of Suleimanié. Sixty deaths were reported to have occurred in the two months. The Kurds in the neighborhood have instinctively proceeded to form an armed cordon around the infested villages, interdicting all communication. The Sanitary Council of Constantinople instructed their representative at Van, Dr. Steptovitch, to proceed to the villages, and investigate the disease. The doctor endeavored to obey his orders, but was not permitted to enter the villages. His report indicates, however, that the disease is decidedly the plague. A quarantine guard has been placed along the frontier, and every measure taken to prevent the introduction of the pestilence into Turkish territory.

OBITUARY RECORD.—Died, at Washington, on the 24th inst., JAMES CROXALL PALMER, M. D., late Surgeon-General, United States Navy, aged 72 years. Dr. Palmer was born in Baltimore June 29, 1811, and graduated in the arts at Dickinson College, Pennsylvania, in 1829. He then begun the study of law, but subsequently relinquished this profession to enter the navy. Being too old to enter as midshipman, he studied medicine, and on March 26, 1832, he was commissioned Assistant-Surgeon, having just received his degree of M.D. from the University of Maryland. In 1838 he was ordered to the store-ship "Relief," of the exploring expedition under Lieut. Charles Wilkes, and was subsequently transferred to the sloop "Peacock," whose adventurous cruise and subsequent wreck are recorded in the history of the expedition. On September 27, 1841, Dr. Palmer was commissioned as surgeon. In 1865 he was apppointed Fleet Surgeon of the Western Gulf Blockading Squadron, commanded by Admiral Farragut, and was attached to the flagship "Hartford" at the battle of Mobile, August 5, 1864. On 3d of March he was commissioned Medical Director, and on the 10th of June, 1872, as Surgeon-General. From that office he was retired, according to law, on June 29, 1873.

—— At Columbia, S. C., on 18th of April, EDWARD BERRIAN TURNIPSEED, M.D., aged 54. He was a native of this country, and a graduate of the South Carolina Medical College, in Charleston. He subsequently studied two years in the Paris hospitals, and at the outbreak of the Crimean War joined the Russian Army as surgeon-major. He distinguished himself during the siege of Sebastopol, and was made a Knight of the Orders of St. Anne, St. George, and St. Andrew respectively by the Czar. He returned to America in 1856, remaining in New York until 1859, when he came to Columbia, where he has since pursued a general practice, giving a preference to surgery.

—— At Hartford, Conn., on 17th of April, GEORGE B. HAWLEY, M.D., aged 72 years. Dr. Hawley was for many years a prominent physician in Hartford. He died at the Hartford Hospital, of which he had been a director from the time it was founded, in 1854.

—— The death is announced of DR. D. JUAN BABÉ, one of the editors and founders of *La Gaceta Medica de Catalana.*

—— DR. MONTALIER, one of the most esteemed members of the medical faculty of Bordeaux, died on March 24, at the age of sixty-four years.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 16 TO APRIL 23, 1883.

SCHUFELDT, ROBERT W., *Captain and Assistant Surgeon.*—To report in person to the President of the Army Medical Examining Board, in session in New York City, for examination for promotion, on completion of which to return to proper station.—*Par. 10, S. O. 87, A. G. O., April* 16, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

FISTULÆ COLLI CONGENITÆ.

A Clinical Lecture, delivered at the College of Physicians and Surgeons, New York.

BY GEORGE M. LEFFERTS, M.D.,

CLINICAL PROFESSOR OF LARYNGOSCOPY AND DISEASES OF THE THROAT.

GENTLEMEN: A chance presents itself to-day of demonstrating to you a very rare case, and, in connection with it, of calling your attention to a very unusual subject. I do both with pleasure, and congratulate you and myself upon the opportunity, for although the condition on which I shall lecture to you must perhaps be regarded from a practical point of view as a curiosity only, still its inherent interest, involving as it does a study of the laws of human development, the great rarity of its occurrence and the paucity of its literature, hence the general unfamiliarity with it, render it one of more than passing scientific value, and one with which it is desirable that you should at least have a cursory knowledge. To-day, the chance occurs of acquiring it. I accept and utilize it for you. It *may* speedily fall to your lot in practice to meet with such an instance as that now before you; you must meet it with understanding, and in preparing you to do this, I likewise prepare you to appreciate your good fortune in having such a rarity thrown across your professional path to enliven it.

A strong and well-formed young man presents himself for our inspection. As far as we can see, he is free from any marked deformity or congenital malformation, and he assures us that this is also true for those parts of his body which are covered. This is an important point, for the congenital defect of the neck, which will claim our special attention, is not infrequently associated with malformations of other parts. He has visited the clinic for the purpose of having an ordinary naso-pharyngeal catarrh treated, and, while detailing his symptoms, has incidentally called attention to the peculiarity of his neck. He knows that something is wrong, but the condition having been present as long as he can remember, and giving him no trouble, he has never paid any special attention to it. We, appreciating its interest, will do so. Let us examine; you will have to look closely. A minute opening, no larger than a pin's head, upon which I now place my finger, is located, as you see, to the inner border of the sterno-cleido-mastoid muscle, upon the right side, and a little above the level of the cricoid cartilage. As the patient swallows, you notice that it is drawn upwards and inwards, and becomes slightly funnel-shaped. It is a small, round perforation through the skin, with smooth, flat edges; looks indeed very much like the opening that a large pin stuck through a bit of paper would make. There is no redness, no swelling of the surrounding parts, nothing that would attract special attention to the little opening. As I press from above downwards on the neck, a drop of clear, viscid mucus exudes from its mouth, and separating the lips, as I can slightly do, I see a pink mucous membrane. How far inwards or in what direction does the canal, of which this is evidently the mouth, extend? This question I can only answer after using a probe, and of necessity a very fine one. Watch now as I pass it; it at once takes a direction upwards and slightly backwards. With some little manipulation, but no force, I cause it to pass along the side of the thyroid cartilage, then backwards towards the angle of the jaw; here it stops; and the patient, who has meanwhile complained of a tickling in his throat, coughs. This would lead me to suppose that perhaps the point of the probe had passed into the lower pharynx, but of this I am not sure. I could not see it there when I looked with the laryngoscopic mirror a few moments ago, after passing the probe, as I have just done before you—and again I seem to have reached the end of the fistulous tract—and entered a *cul-de-sac*. I diagnosticate the fistula then as an incomplete one, having an external mouth only. I might, in order to prove this view, inject the sinus with some solution, colored or otherwise prepared, so as to be recognized or tasted by the patient, if it entered the pharynx through an internal opening, but I judge it to be unnecessary. What are its precise direction and relations? The probe can be felt in the canal throughout the greater part of its course; this helps us to decide; and judging from the known direction taken by this form of fistula, I know that it has probably passed first under the deep cervical fascia, then along the outer border of the thyroid cartilage, parallel with the sterno-mastoid muscle, thence above the sheath of the great cervical vessels, under the digastric muscle and above the hypoglossal nerve, to somewhere near the posterior border of the palato-pharyngeus muscle. Had it continued its course—had the case been one of complete fistula, with internal as well as external mouth—the lateral pharyngeal wall would have been perforated just here, and the inner mouth of the canal been found perhaps by a sharp eye, just below the pharyngeal orifice of the right Eustachian tube. I now withdraw the probe, and, on feeling for the fistulous tract, discover its lowermost portion easily by the sensation conveyed to my finger of a hard, thick cord beneath the skin. I move it slightly to and fro. This size is not due to the calibre of the fistula alone, but more especially to the dense connective-tissue adhesion of the little canal to the surrounding parts. The fistula itself is small, with thin, elastic walls, and lined with mucous membrane. It is wider within than just at its mouth, but still it is very small.

I do not know that we can gain any more information by further examination. Let us recapitulate the results already obtained, and see in what position they place us as regards the question of diagnosis. We have demonstrated the presence of a small, narrow, fistulous tract, connecting with surrounding parts, and extending upwards from the region of the cricoid to somewhere near the right lateral and lower pharyngeal wall; that here it terminates in a *cul-de-sac;* that its mouth is minute, rounded, and shows no signs of irritation; that its presence is unaccompanied by any marked subjective symptoms; and that the lesion is congenital, or at least has existed since the patient's earliest recollection. If I eliminate now one or two conditions with which the present one might be confounded—mainly, salivary, tracheal, and glandular fistulæ—I shall be ready with my diagnosis. Salivary fistula it cannot be—its position and course forbid; moreover, its secretion, slight in quantity and viscid, is widely different from saliva. Tracheal fistula (congenital) is rare; even if it ever occur, the fistulous

canal in this case evidently does not communicate with the air-tract. Glandular fistula requires a moment's more thought, for it would be most easily mistaken; but no. A glandular fistula—one originating in the degeneration or suppuration of an enlarged lymphatic—is not uncommon in the neck, but there is nothing congenital in its character; it differs in its discharge, in its appearance, and in its being associated with other strumous indications from the present case. The clinical history allows us to at once dismiss any thought of the fistula being due to injury of neck, disease of the laryngeal cartilages, or the like, and I hesitate no longer to announce to you that the case is one of incomplete, with external mouth, congenital fistula of the neck—technically, a cervico-branchial fistula—the *Halskiemenfistel* of the Germans, although it has never before been my fortune to meet with an instance.

Let me now, using our case as the clinical illustration, review briefly for you the interesting subject of congenital fistulæ of the neck. Two forms only exist—aerial fistulæ, a term which explains itself, and cervico-branchial fistulæ, of which I shall speak more precisely in one moment; of the first, I need not say much; indeed, there is not much to say. Fistulous openings, or, more rarely, fistulous tracts, communicating directly with either the larynx or trachea, and existing only as the result of an arrested development of the primitive canal—congenital, in other words, in their origin—are extraordinarily rare. The small, round, external mouth of the fistula always lies in the *median* line of the neck at some point, an important diagnostic difference from the opening of the cervico-branchial fistula, which is always, or with very rare exceptions, located *laterally* or *bilaterally;* and I may here again call your attention to the fact that the former always opens into the air-tube, the latter never, always into the pharynx—in either case, of course, if it be complete. Mark now the obscurity which envelops the subject. A congenital, aerial fistula, communicating directly with the larynx, is, it is said, unknown. A few cases are reported, but are doubtful, in which a complete fistulous tract commenced over the lower edge of the thyroid cartilage, or over the middle of the upper tracheal ring, and extended thence to a point above the upper border of the larynx, where it entered the air-tube. In one instance only has the tract extended downwards, and entered the trachea. On the other hand, instances are more common—if the term common can be applied to such a rarity—where an incomplete fistulous passage commencing in the median line of the trachea, lower down, extended downwards towards the *manubrium sterni*, and ended in a *cul-de-sac*. But, really, the question is of little practical importance; little is absolutely known about it, and we need not dwell upon it. The very possible existence of the condition is denied by some authors.

I turn then to the second variety of fistula, the cervico-branchial. The subject is much more interesting, but my limited time will oblige me to curtail much that I should like to say to you, especially concerning the development of the branchial arches in mammals, a correct understanding of which process is necessary for the subsequent explanation of the abnormalities under notice. I can but condense for you the information that is to be gained by the study of an elaborate article by Cusset, and this I do, first acknowledging my indebtedness to him, and my admiration for his masterly essay.

The face and prevertebral portion of the neck, he tells us, are developed in all vertebrata at the expense of a branchial apparatus composed of a series of parallel arches—four in number—separated by clefts; in man, this condition is transitory only—the morphological changes, by which the arches and clefts disappear, are subject to regular laws and any causes hindering the development and closure of these arches tend to make permanent some transitory condition; hence, numerous abnormalities from monstrosities to simple fistulæ and cysts, of which latter, I cannot speak to-day—I confine myself to the fistulæ alone.

The arrest of development, which gives rise to the fistulous tract, may occur along any of the lines of clefts between the branchial arches, but the cleft usually at fault is the fourth or that below the fourth arch, and the line along which most of the abnormalities have been observed, corresponds with the anterior border of the sterno-mastoid muscle. In most cases, also, the external orifice was situated just above the episternal notch, and the sinus has run thence upwards in the manner that I have described in speaking of the case before us—terminating in either one of the two ways that I have mentioned. Along the lines of the three upper clefts fistulæ occur more rarely, and the orifice usually selects a definite position in each cleft. When the third cleft is at fault, the origin of the fistula is usually found in the neighborhood of the thyroid cartilage, as in our case. If the second, at the great cornua of the hyoid bone; and if the first, along the edge of the lower jaw or at its angle.

Now, as to concurrent abnormalities: Do they exist in such cases? Yes, but as a rule only, I believe, when the arrest of development affects the first cleft, or is between the first and second branchial arches. The auditory apparatus is developed here to great extent, and deformities of the ear and deafness sometimes accompany the branchial fistulæ; abnormalities of the lung, hare-lip, and cleft-palate have also occasionally been noticed. The hereditary character of the lesion is always marked, pronounced when the fistula is complete. Sex has no influence.

Bear with me now, for a few minutes longer, while I allude to certain points in connection with these lesions, which are of importance and will perhaps be of more interest to you than those of which I have just spoken. I shall be brief. From what has been said, you have learned that a branchial fistula may be, (1) complete; (2) with external orifice only, this is the commonest form; and (3) with internal orifice alone. The latter class, let me say, is not only rare, but is doubtful. A diverticulum, in the very few recorded instances, has existed from the side of the pharynx, it is true, but this may have been only an œsophageal hernia, and not an incomplete fistula; the question is difficult to decide.

Some figures that I have here jotted down give additional and valuable facts. They relate to the whole number of cases collected by Cusset; since the date of his essay, I may say but two or three are reported, as far as I am aware, in all certainly less than one hundred instances are recorded in all literature.

Of the cases of complete cervico-branchial fistulæ, 18 are referred to, or 23 per cent. of the whole number. Cases with external orifice alone 52, or 69 per cent. of the whole, proving the statement that this is the commonest variety. Of those with internal orifice, only 5, or 8 per cent. of the total, but these—as I have told you—are doubtful. As regards their location, in 25 per cent. the fistula was bilateral, in such cases the fistulæ converge as they ascend in the neck, in 46 only on the right side, in 17 on the left, and 8 were median—a rarity which complicates the diagnosis, unless care be taken to explore the tract thoroughly, and differentiate it from that of an aerial fistula. The figures also show that the hereditary character of the lesion was marked (30 per cent.), and that if this tendency existed, the fistula was usually a complete one.

The question now arises, and it is the last to which I shall call your attention: Shall such fistulæ be surgically interfered with, or shall they be left severely alone? Much depends, of course, upon the nature of the individual case. Occasionally the obstinate persistence of the fistula gives rise, not only to a deformity which is annoying to the patient, and for which he will be likely to seek relief at your hands, but it may be to more serious symptoms; such have been reported. If the external orifice closes, and closure of one or the other orifices of the fistulous tract, in the course of time, does not appear to be unusual, accumulation may take place somewhere in the sinus and give rise to severe pain, aphonia, and epileptic seizures, as well as interference with deglutition or with respiration; the latter either directly by pressure on the trachea or larynx, or, it may be added, by involvement of nerve-filaments in the part irritated: for it is a curious feature, that in several of the instances reported, interference with the fistula excited irritability of the bronchial mucous membrane.

In such cases, but I conceive that they are rare, it may be necessary to effect the obliteration of the whole sinus; ordinarily they may be left alone, perhaps, my experience with them is not great enough to enable me to judge; certainly in the present case this is the advice that I shall give the patient. The earlier attempts to effect the closure of the sinus by means of nitrate of silver in substance or injections of a solution, were unsuccessful. A permanent or successful cure, can only be attained by complete destruction of the mucous membrane lining the whole canal, and this is confessedly difficult. Complete fistulæ are the most intractable; and the danger always would be, that the outer opening might be closed, and the inner remain, converting the case into one of fistula with internal mouth, a condition more dangerous perhaps than the original disease. Iodine injections have effected a partial cure, by causing the closure of the small inner orifice in complete fistulæ; but it must be added have, in more than one case, caused also alarming symptoms. Complete ablation of the mucous membrane of the fistulous tract, appears to be the most successful procedure, as I have said, a bougie being used in the sinus as a guide for the knife; Weinlechner and Sarazin have thus happily operated. But remember, gentlemen, that the close connection of the fistula with very important blood-vessels and nerves, causes such an operation to be more or less of a hazardous one. This is also true of the use of the galvano-cautery, and I feel that I am giving you good and sound advice, when I caution you as I now do, to pause, especially if you should meet with such an instance of the affection as that now present, before you resort to the reckless and inconsiderate use of such heroic means—"Discretion is the better part of valor."

ORIGINAL ARTICLES.

THE WEAK POINTS IN A LISTER DRESSING, AND THE ADVANTAGES OF CORROSIVE SUBLIMATE AS AN ANTISEPTIC.

BY ROBERT F. WEIR, M.D.,
SURGEON TO BELLEVUE AND THE NEW YORK HOSPITALS.

(*Read before the New York Surgical Society, April 10, 1883.*)

IT must be admitted by the most devoted of the advocates of Listerism, that the dressings applied with the strictest attention to all the details of this system, not infrequently fail in controlling the progress of putrefaction. This is the case, not only in a severely lacerated wound, but also at times in a comparatively simple one.

It is difficult in all cases to explain why this should be so; in many, no doubt, some error in the technique may have been committed by the surgeon himself; in certain other cases it must be assumed either, that the antiseptic itself, *i. e.*, the carbolic acid, is at fault or has been wrongly applied, or that the dressings are themselves imperfect in construction.

In connection with these two points, considerable vagueness has been encountered. According to Mr. Lister, who started with a solution of 1 part of the acid to 100 parts of water, the solutions to be employed now, are for the instruments, hands, etc., 1 part to 20; for the spray, 1 to 30; and for the sponges, etc., 1 to 40. Why should such diversity exist? What strength, in other words, is necessary to arrest or destroy bacteric life in a wound. Clinical experience has generally settled on the range of strength given by Lister, to wit, from two and one-half to five per cent. of the acid, but the application of laboratory tests does not apparently accord with this conclusion. For instance, in an article by Delacroix[1] it is stated that ten per cent. of carbolic acid is required to destroy bacteric life, and in the very careful and much to be admired investigations of Koch[2] it is likewise recorded that one per cent. solutions of carbolic acid are necessary for safe or sure disinfection, and that the anthrax spores were destroyed in a four per cent. solution only after three days, and in a five per cent. solution only after two days' immersion. These statements have been widely quoted, and have much embarrassed observers by their variance with clinical work, but on reference to the articles themselves, and particularly to that of Koch[3] "On Disinfection," published in the *Reports of the Imperial Board of Health* for 1881, there will be found a reason for the discrepancy. It consists in this, that the experiments have properly been conducted upon the *spores* of the anthrax bacillus as being the most resistant to disinfectants of all such micro-organism. These spores are much more difficult to affect than the bacilli themselves. To show the influence of weak solutions upon the bacilli themselves, a number of tests were applied by Koch, by soaking silk threads in the juice expressed from the spleen of a mouse affected with anthrax bacilli, and then wetting them with one, two, three, and five per cent. solutions of carbolic acid for periods varying from two, five, ten, fifteen to twenty-five minutes; after these had been placed in a gelatine culture-glass, no signs of development occurred, showing that all life had been arrested. In the several preparations, however, of the same impregnated threads which had not been dipped in the carbolic solutions, there were to be found in the gelatine culture-glasses marked development of bacilli and even of spores. Again, a one per cent. solution of

[1] Archiv f. Experimentelle Pathologie, Bd. xiii. hft. 3 and 4, 1881.
[2] Koch, p. 242.
[3] Mittheilungen aus dem Kaiserlichen Gesundheitsamte, Berlin, 1881.

carbolic acid with an equal quantity of anthrax blood injected into a second animal proved innocuous, but a one-half per cent. solution failed to neutralize the poisonous blood. Similar observations were carried on in respect to less obdurate micro-organisms, including the micrococci found in septicæmia; and from a large experience gathered in this manner Koch formulates the statement that carbolic acid in one to five per cent. watery solution is a good disinfectant for those organisms which have not passed into the *Danerform* or the condition of spore growth; and that 1 part to 400 of water, *i. e.*, ¼ per cent., must be *permanently* present to control life in the bacteria met with in wounds. Note carefully here the use of the words permanently present, and it must also be remembered that to produce this condition stronger solutions are of necessity to be employed.

More recently these experiments have been repeated, with a corresponding result, by Dr. Sternberg, of the U. S. Army, who has found, by the test of flask culture in reference to carbolic acid, that a 0.2 per cent. solution of this acid would so act on septic micrococci as to prevent development, but that a stronger solution was required for the micrococcus of ordinary pus. This observer, reiterating the remarks of Koch, that the resisting power of reproductive spores is far greater than that of bacterial organisms in active growth (multiplication by fission), says that the quantity of carbolic acid to be used as a germicide shall not be less than five per cent., for it is necessary, he states, to keep on the safe side, since we do not know whether all of the pathogenetic bacteria form spores or otherwise.

These considerations, which might be extended by debating more at length the steps of the various experiments, or by quotations from the observers, are sufficient to explain the satisfactory results that follow the present use of carbolic acid in the treatment of wounds, and to show us that the antiseptic has, in the main, hitherto been rightly used. In looking further for causes of error, some may perhaps be found in the imperfection of the dressings. Tests of the strength of the gauze employed revealed to me in January, 1880, that the strength of this part of the dressing varied much with its age. Gauze impregnated after Lister's formula, and kept in a tight box, wrapped up in rubber cloth, gave, at the end of three months, 1.44 per cent. of carbolic acid, and another specimen, similarly prepared and preserved, showed, at the end of three weeks, 1.82 per cent. These observations have been confirmed by Kopff, who found, on the second day after gauze had been impregnated, according to Lister's and Brun's method, that the former contained 2.61 per cent., and the latter 5.62 per cent. In the gauze sold in the shops, only one-half per cent. of carbolic acid was found. The gauze, when used, therefore, should be freshly prepared, for which purpose Brun's formula is the best:

R.—Resin,	400 gr.
Carbolic acid,	100 gr.
Castor oil,	80 gr.
Alcohol,	2 litres.

Another possible cause of failure in an antiseptic dressing is encountered in the catgut ligature. Made, as it is, from the intestine of a sheep, it is not to be wondered at that the possibility of infection thereby should have been considered. Few, however, have been the facts that confirm such a suspicion. Koch calls attention to this, and De Lauti[1] more recently repeats this caution, and quotes Zweifel, of Erlangen, who accused the catgut of being a cause of infection in wounds. Kocher, of Berne, also furnishes a case where apparently the septicæmia was due to this cause; and Volkmann reports two cases of malignant pustule from the inoculation by means of anthracized catgut.[2] In investigating this point, Koch has found, by careful experiment, that solutions of carbolic acid in oil or alcohol are absolutely inert in respect to their action on bacteric life, either on the spores or bacilli. He took solutions of one and five per cent. of carbolic acid in oil, and also pure oil itself, and tested them with the anthrax bacilli and other micro-organisms, and found that bacteric life was arrested in the pure oil at the end of six days. The same took place in each of the carbolized solutions. The same, moreover, occurred in the several experiments, where the bacilli were exposed to the air on gelatine. In other words, no influence was exerted by carbolic acid when mixed with oil. The bacilli lived as long in oil and oily solutions as in the condition of culture. When the *spores*, however, of the anthrax bacilli were introduced in the carbolized oil solutions, reproduction could be accomplished after three months' immersion. The same results were met with in oily solutions of thymol and salicylic acid.

In explanation of the antiseptic action of carbolized oil as a wound dresssing, Koch, however, remarks that "When it comes in contact with substances containing water, as, for instance, the tissues of the human body, wounds, etc., then it undoubtedly gives up part of the acid to these, and in this way an antiseptic effect may be obtained. But this holds good only in cases where aqueous fluids come in contact with the oil. In all other instances, where dry substances, such as silk, catgut, instruments, etc., are to be disinfected by carbolic oil, not the least antiseptic effect is to be expected, even upon the most vulnerable micro-organisms." These investigations, it may be added, have been fully confirmed by those of Wolfhügel and Knowe in the same volume of reports. Kocher, of Berne (already quoted), also made sundry experiments bearing on this point. This surgeon placed ordinary catgut, with all the customary precautions, in sterilized fluids, which became turbid from bacteric development within twenty-four hours. He also found that if the catgut were steeped for twenty-four hours in the oil of juniper, and kept in ninety-five per cent. of alcohol, it would not develop bacteria in sterilized fluids.

I do not know of any experiments that will determine whether the chromic acid used to render

[1] Arch. Gén. de Médecine, March, 1883. "Les devices Evolutions des Imements Antiseptiques."

[2] Deutsche Zeitschrift f. pract. Med., No. 18, 1877.

the catgut ligature more durable makes them at the same time aseptic, but we have information relative to sulphurous acid, which will be somewhat startling to the surgeons in this city, who have relied upon this gas as a proper disinfectant for their contaminated hospital wards. Two investigators, Koch and Wolfhügel, pronounce decidedly against sulphurous acid in gas, and in watery solutions as a disinfectant, *i. e.*, as an arrester of bacteric life. Koch says no real value can be claimed for it, and in none of the experiments conducted with it did it succeed in destroying all the germs present. The reliability of the tests of Koch and his assistants should attract attention to this point, as not only is this agent largely employed here in hospitals as above alluded to, but it is likewise recommended to the public by our health boards for disinfection after scarlatina, diphtheria, and other contagious diseases. I may remark, in passing from this portion of my subject, that the most reliable disinfectant for closed spaces was presented by bromine, and ranking a little lower was chlorine, the less expensive. Returning to the catgut, it must be admitted that, while thus open to the suspicion of a septic agent, yet the daily experience of surgeons has taught that its principal defect was in its unsatisfactory solubility. Since the addition of chromic acid and sulphurous acid to it, its durability in the tissues has been too much increased, and though the latter acid has permitted the catgut to be kept in a dry state and the oil thus avoided, yet I have found that it will not dissolve for twenty or thirty days, and that it often acts as a foreign body. Weakening both the acids has improved it somewhat, but my experience in this line has not been sufficient to speak yet with positiveness.

The probing of scientific research has in this way revealed to us some of the weak points of the carbolic dressing, but notwithstanding this and the earlier condemnation of the spray by Trendelenburg, Bruns, Mickulicz, Wernich, Duncan, and others, a verdict which is, however, not accepted by Lister, Nussbaum, Rydygier, Shiene, and their followers, Lister's dressing has remained until very recently the best for surgeons to employ, though other antiseptics, and notably iodoform, have given very satisfactory results in other hands. The volatility of the former antiseptic, and the toxic properties of both those named were decided disadvantages. Very lately an old remedy has appeared in this *rôle* of an antiseptic. This is the corrosive sublimate or the old bichloride of mercury—the mercuric bichloride of the newer nomenclature.

My first experience with this salt as a wound-dressing was obtained after reading an excerpt from the article of Delacroix, in which it was stated that corrosive sublimate in the proportion of one part to 2525 parts of water was an effective germicide—being 250 times more powerful than phenol or carbolic acid—with this imperfect datum I used it in the spring of 1882, in one part to 2000 of water as a dressing to three compound fractures of the thigh and six of the leg, with very satisfactory results. So much so that when I resumed my service in the New York Hospital, in November last, the dressings were continued, but with some slight modifications; these were first, that it was found that the strength was insufficient—active bacteric life being at times found under the dressing—and also from the fact that a perusal of the large experience of Kümmel and Schede, of Hamburg, showed that a stronger solution was required, and that it was free from the risk of toxic effects. For of over two hundred cases presented by Kümmel, in only two were there any constitutional symptoms observed, and then only as a slight salivation. This surgeon says of the sublimate dressing, that the healing of wounds is accomplished with a certainty and uniformity unknown under the strictest Lister dressing; and in 212 extensive wounds, as recently treated by the sublimate solutions and peat dressings by Esmarch and Neuber, who recommend it strongly, there was no poisoning and only 3 deaths. In this number were 30 major amputations, 32 resections and osteotomies, 5 herniotomies, 14 cases of nerve-stretching, etc., and in only 11 cases was the dressing changed more than once. Bergmann, whose experience with the remedy has also been large, also lauds it. My own observation of the efficacy of the sublimate dressing, after I had properly achieved the correct method of using it, is yet comparatively slight, embracing four cases of necrosis of the foot and tibia; one amputation at the hip-joint; one amputation of the thigh; one amputation at the knee; one amputation of the leg; one amputation of the breast; two removal of tumors; one fixation of a movable kidney; one extensive laceration of upper thigh—died twelfth day of septicæmia; one subdeltoid bursa; three compound fractures of leg; with recovery in all except the case above noted. In two of the compound fractures, an aseptic condition was not preserved; in one of these the solution was too weak—1 : 2000; in the other a 1 : 400 peat dressing was used, although, by error, solutions of 1 : 100 were several times resorted to. No special local effects were produced beyond, in one instance, slight pustulation of the adjacent skin; no constitutional effects were noticed in any case.

Let me hastily indicate the mode of employment of this dressing. Carbolic acid solutions are used by Neuber, Kümmel, and Bergmann for the spray and for the instruments, and sometimes for washing out the wound. The sponges and compresses are wet with a solution of the sublimate, 8 grs. to the pint (solution No. 1). Silk, if used for sutures, etc., is dipped for two hours in an 80 gr. to Oj solution, and then permanently kept in the 80 gr. solution. Catgut, as used by Kümmel, is made by immersing it in an 80 gr. to Oj solution for twelve hours, and then it is wound on bobbins, and kept in an alcoholic solution of twenty grains to the pint, with one and a half ounce of glycerine added.[1] The gauze is prepared by immersion in a solution of 20 grs. to the pint of alcohol, with ℥iss of glycerine. Drainage is accomplished by rubber tubes, or by spun glass, twisted or plaited. If sand is used as an ab-

[1] This catgut dissolves too quickly in a wound. Some recently used proved more satisfactory where—after the corrosive impregnation had been secured—the gut was dipped for two hours in a 1 to 1000 chromic acid, then dried, and kept.

sorbent, after being heated in a crucible it is mixed in the proportion of 1 lb. to ʒj of sublimate, dissolved in ʒijss of sulphuric ether. The sublimated sand is put in thin cotton bags, of various sizes, from 12 to 40 cm. square, which have been frequently washed with green soap and soda, rinsed, and finally dipped in the 8 gr. to the Oj solution. Peat, sawdust, and other absorbents are also employed,[1] according to the judgment of the surgeon. It has been found, in my wards, that while pure sawdust has absorbed readily, yet a disagreeable, sour odor was often noticed, even where the underlying wounds were doing perfectly well.

A few words more will complete these necessarily incomplete remarks. The experiments of Koch evidently excited the surgeons of Hamburg, Würzburg, and Kiel to the use of the mercuric chloride as a surgical dressing, and as the results of this able investigation have not been very widely disseminated on this side of the Atlantic, I beg to summarize them here: After applying a number of tests similar to those employed in connection with a number of so-called antiseptics and disinfectants (a partial list of which is here appended—Table I), he found that simply moistening the anthrax spores (the most resistant of all, it will be remembered) with a solution of 1 part of corrosive sublimate to 5000 of water, destroyed them thoroughly and immediately; and the destruction would equally happen if they are immersed for a longer time in solutions as weak as 1 to 20,000. He then says that the sublimate is the only known disinfectant which succeeds by a single application of a few minims of a solution of sublimate of 1 part to 1000 in destroying the most resistant micro-organisms. He also furnishes us with a test as to the strength required in a wound dressing. There should be present in a dressing an excess of corrosive sublimate equal to 1 part to 5,000; this will be readily recognized by leaving a thin strip of polished copper for half an hour in the dressing; if the excess is present, an amalgam will show itself; this seldom occurs in a 1 to 10,000 solution.

Naturally with so potent a bacteric arrester, the idea comes into birth—Cannot the internal administration of the remedy be utilized in germ diseases? Koch's experiments on anthracized rabbits by injecting sublimate solutions, however, were negative, Sternberg, estimating the blood in an adult of one hundred and sixty pounds to be twenty pounds, ascertained that the quantity of corrosive sublimate required to affect this amount of blood would be three and one-half grains, and believes that although one grain per diem is the maximum quantity which could be administered for several days, that a cumulative effect might be produced by its use sufficient to exert some restraining influence on the development of micro-organisms within the system.

The annexed tables, taken from Koch and Sternberg's papers, give an interesting *résumé* of the germicidal power of a number of agents, some of which have wrongly been relied upon:

TABLE I (FROM KOCH).[1]

= indicates life destroyed totally

Sublimate corrosive, 1 per cent., in water, destroyed all bacteric life in	1 day.
Permanganate of potassium, 5 per cent., in water, destroyed all bacteric life in	1 "
Permanganate of potassium, 1 per cent., in water, had no effect at end of	2 "
Osmic acid, 1 per cent., in water,	1 "
Turpentine, oil of,	5 "
Chlorine water, freshly made,	1 "
Bromine, 2 per cent.,	1 "
Iodine water,	1 "
Chloride of lime,	5 "
Chloride of iron,	6 "
Iodine in alcohol, 1 per cent., hindered growth only.	
Arsenic, 1 per cent.,	10 "
Sulphurous acid water, very slightly efficacious.	
Sulphuric acid, 1 per cent., growth hindered in	10 "
Quinine, 1 per cent.,	10 "
Boracic acid, 5 per cent., practically unreliable—spore growth only hindered in	61 "
Borax, 5 per cent., no effect at end of	15 "

TABLE II (FROM STERNBERG).[2]

CARCINOMATOUS OSTEOMA OF THE FEMALE MAMMA.

BY SAMUEL W. GROSS, M.D.,

PROFESSOR OF THE PRINCIPLES OF SURGERY AND CLINICAL SURGERY IN THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA.

MRS. ——, seventy-four years of age, and the mother of seventeen children, discovered, in May, 1880, a tumor as large as a pea in the left breast, which gradually developed some of the signs of scirrhous carcinoma, such as extreme hardness, retraction of the nipple, and lancinating pains, without, however, deep attachments or involvement of the axillary glands. The entire breast was removed,

[1] The absorbing power of—

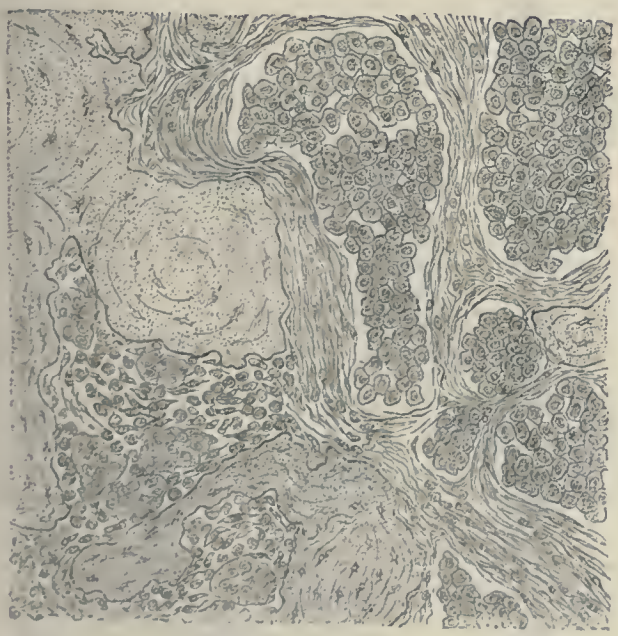
[2] Amer. Journ. of the Med. Sciences, April, 1883.

on the 10th of November, by Dr. Hunter McGuire, of Richmond, Va., who found a bony tumor loosely embedded in the organ, which he kindly presented to me.

The neoplasm was almost spherical, nodular, densely hard, and inelastic, and enclosed in a connective-tissue capsule, through which it was thoroughly isolated from the surrounding tissues of the mamma. On section, which could only be made with a saw, it measured three centimetres and a half in diameter, and the cut surfaces presented a pale, granite-like appearance, with white islets of fibrous tissue, which constituted about one-sixth of the entire mass, including a peripheral margin one millimetre in diameter for about one-half of its circumference.

Minute examination of sections treated with hydrochloric acid, conducted by Dr. H. F. Formad and myself, disclosed—as is represented in the accompanying drawing, made with the aid of the camera lucida, and kindly furnished by Dr. Formad—an osseous framework, the meshes of which were filled partly with a lymphoid tissue containing giant-cells, and representing young bone-marrow, and partly with glandular tissue undergoing carcinomatous transformation or completely converted into typical carcinomatous structure, *i. e.*, an alveolar fibrous stroma, containing cylinders or plugs made up of epithelial cells. At rare intervals the acini were normal.



The tumor was evidently, in the first instance, a fibroma containing glandular elements, or an adenoid fibroma, which was gradually being transformed into an osteoma, when the irritation of the plates of bone excited atypical growth of the cells of the acini, through which carcinoma was engrafted upon it. The presence of a fibrous capsule, whereby the neoplasm was isolated from the remainder of the mamma, was of itself sufficient to exclude the idea of primary osteoid carcinoma; and this view is strengthened by the freedom from local recurrence and invasion of the axillary glands, as the patient remains well two years and four months after the operation.

As I have pointed out in the chapter on Fibroma in my *Practical Treatise on Tumors of the Mammary Gland*, ossification is a very uncommon transformation of a fibroma; and I may add that, as far as I know, the specimen now described is unique.

1112 Walnut Street, March, 1883.

MEDICAL PROGRESS.

Injection of Perosmic Acid.—Prof. Winiwarter reports the case of a man with a soft sarcoma in the right side of the neck as large as a baby's head, and adherent to the vessels and nerves of that region. As it could not be operated upon, Prof. Winiwarter decided to practise injections of perosmic acid. For fourteen days he injected daily about three drops of an aqueous solution (1 to 100) of the acid, at the end of which time the tumor was completely broken down. The broken-down parts mixed with sero-pus, were evacuated by an incision, which rapidly cicatrized. One month after treatment was begun there was no trace of the tumor. The skin was intact, and there were no symptoms of local inflammation. This treatment was afterwards adopted in a similar case of sarcoma of the shoulder, in a number of cervical tumors, in cervical adenitis of scrofulous origin, etc. It was also employed in glandular tumors of a carcinomatous nature. The dose in some cases was as much as half a syringeful. Several years ago Dr. Moore used acetic acid in similar cases in the Middlesex Hospital.—*Gaz. Méd. de Nantes*, April 9, 1883.

Total Blindness from Concussion of Brain.—Surgeon A. Pierson, M.R.C.S., records the case of an Indian cavalryman who fell from his horse while on parade, and sustained a concussion of the brain. From the first his eyes were closed, and he could only partially open them, the orbiculares being both firmly contracted. There was great pain in the head, and the pupils were found to be contracted. Photophobia prevented ophthalmoscopic examination. When he was able to open his eyes, it was found that he could only distinguish objects very imperfectly. This latter condition increased rapidly, and the patient finally became totally blind. On Jan. 1, 1883, eight months after the accident, he was still totally blind, and his general state bad. Mr. Pierson diagnosticated hemorrhage from rupture of a vessel in the pia mater, occurring about the position of the optic commissure, with subsequent inflammation around the clot, and disorganization of the nerves.—*Proc. N. W. Provinces and Oudh Br. Brit. Med. Ass.*, Feb. 1883.

Diaphoretic Treatment of Puerperal Eclampsia with Hot Baths.—Dr. Carl Breus, assistant to the clinic of Prof. Braun, in Vienna, in an article in *Archiv f. Gynäkol.*, Bd. xxi. Hft. 1, 1883, strongly advocates the treatment of puerperal convulsions by immersing the patient in baths of a temperature of 100° F. Details of sixteen cases are given, in thirteen of which the convulsions appeared at or near the beginning of labor. Craniotomy was performed in two, and the forceps used in four of these cases. In two cases, convulsions appeared in the second stage,

with one forceps delivery. One death occurred, due to pelvic abscess and peritonitis. Chloral hydrate was freely used in many of these cases, as was chloroform inhalation. After the hot baths, the patients were immediately wrapped in warm sheets and blankets, so as to promote free diaphoresis. As regards the mother and child, the result was, as it seems, satisfactory. All of the children were born alive except the two upon whom craniotomy was performed; and one death of the mother in fifteen cases is a striking result.

MIASMATIC PROPAGATION OF DIPHTHERIA.—DR. FORSTER relates the following cases coming under observation at the Children's Hospital, in Dresden, and which, in his opinion, go far to prove the miasmatic origin of diphtheria. Tuberculous boy, æt. 6, with no infectious disease, was brought into the ward on Nov. 18, 1881. On the following day he was taken with diphtheria and was immediately transferred to an isolated ward. In the ward in which the disease appeared first, two other cases appeared on the same day, and on the 9th of May following, eleven children developed diphtheritis. Two of these died; the remaining nine recovered. Four of these last cases made their appearance in rapid succession, but the remaining seven appeared at long intervals; yet there was sufficient evidence to show that they were due to a miasmatic influence. The patients were so quickly conveyed to an isolated ward, the iron bedsteads thoroughly washed and disinfected, and the mattresses disinfected and unused for so long a time, the walls thoroughly washed and disinfected with carbolic acid, and all the precautionary measures now in use so rigidly adhered to, that it is difficult to account for the persistence of the disease. In the spring of 1880 it was necessary to repair the floor of this ward, and at that time the disease again appeared. It seems almost certain that the propagating material was concealed in the dirt deposited in the grooves of the floor, and that the constant washing of the floor and subsequent drying of the dirt, had much to do with the reappearance of the disease at intervals.—*Medizinisch-Chirur. Centralbl.*, April 6, 1883.

THERAPY OF OSSEOUS DEVELOPMENT.—DR. J. C. THOROWGOOD points out that the mere administration of the necessary lime-salts is not the only thing to be considered in striving to improve osseous development. To give a big-bellied, pale-faced child, with acid dyspepsia (as shown by sour breath, furred tongue with red papillæ showing through, appetite often voracious, and confined or irregular bowels), phosphate of lime and iron, would only make him more uncomfortable. He should have alkaline aperients, diet should be regulated, excess of starch and sugar cut off, and exercise and salt-water baths ordered; then administer the remedies indicated. Of these, soluble hypophosphite of lime and chloride of lime are most useful, given in doses of grs. ij–iij, in glycerine and water. The lacto-phosphate of lime is also valuable. Diet, however, is most important. The child must be made to eat slowly. Brown bread, oatmeal, and "second's" flour are preferable to "extra white."—*British Med. Journ.*, April 7, 1883.

IODOFORM IN DIABETES.—BOZZOLO, though at first disappointed with Moleschott's treatment of diabetes mellitus by iodoform, has recently tried it in two cases with better success. The daily dose was about grs. xxx, a much larger amount than was used in his first cases. In both cases the quantity of urine was lessened; in one mild case the glycosuria entirely disappeared; in the other, which was very severe, the sugar was diminished.—*Gaz. degli Ospitali*, Feb. 4, 1883.

CONSTANT CURRENT IN BRONCHOCELE.—MASSEI, (*Boll. delle Malat. dell' Orec.*), who has used the constant current in bronchocele, speaks of it as a remedy of high value, and draws the following conclusions: 1. The constant current, in simple hypertrophy of the thyroid gland, is a safe, speedy, and harmless remedy. 2. It merits increased attention among physicians. 3. Statistics do not furnish results of treatment beyond simple hypertrophy; in the cystic form, colloid degeneration and nodose hyperplasia, it is a more efficacious means than electrolysis. Massei uses from six to ten elements during a period of six to ten minutes.—*L'Imparziale*, March 30, 1883.

BROMIDES IN NAUSEA AND VOMITING.—DR. CHERON (*Archives de Toxocologie*) has found that great benefit results from the administration of bromides in an effervescing mixture in the persistent nausea and vomiting so often seen in women with uterine affections. His formula is: 1. Bicarb. potass., grs. xxx; water, f℥ij; bromide potass., grs. xxx.—M. 2. Citric acid, ℥j; water, f℥iv; syrup, f℥x.—M. S.—Add a teaspoonful of No. 1 to a tablespoonful of No. 2, and drink immediately. This dose may be repeated every half hour or hour, the quantity stated in the above formula being the maximum *per diem* amount. In localized pelvic peritonitis, this mixture often arrests the tendency to vomit, even in the acute stage.—*Medical Times and Gazette*, April 7, 1883.

NEW PORRO OPERATION.—On the 28th of March, PROF. PORRO performed another operation, at the St. Catherine's Obstetrical Hospital, of amputation of the gravid uterus by the Porro-Cæsarean method. The patient was a primipara, and near the termination of the pregnant state; there was great rachitic deformity of the whole skeleton. The child was healthy and well formed. On April 3d the patient was doing well—maximum temperature up to that time was 100.4°.—*Annali Univers. di Med. e Chirurg.*, March, 1883.

CASTOR OIL AND GLYCERINE AS A PURGATIVE.—MR. SLOPER recommends a combination of glycerine and castor oil, in equal proportions, as being an efficient purgative. The best form is that of a semi-solid, of which a small teaspoonful is an efficient dose; its effect seems lasting, and it does not need continued renewal. The compound may be flavored with lemon, almond, or any other agreeable flavor.—*Lancet.* Feb. 10, 1883.

EPILEPTIFORM ATTACKS IN STRANGULATED HERNIA.—M. CH. LIÉGEOIS reports a case of strangulated inguinal hernia in which the only symptoms were epileptiform attacks, repeated at short intervals. These could not be accounted for in any manner, and it was only when the patient was undressed that the real state of affairs was discovered.—*Gaz. Méd. de Nantes*, April 9, 1883.

PILOCARPIN IN ASCITES.—DR. MAX RICHTER has had excellent results, in two cases of hepatic ascites, from the use of muriate of pilocarpin in doses of gr. ⅙ to ¼ twice a day. He gives whiskey in small doses to counteract the weakening effect of the pilocarpin. In the two cases referred to, it was necessary to tap several times, but the persistent use of the pilocarpin effected a cure.—*San Francisco Western Lancet*, April, 1883.

A THIRD LORETA OPERATION.—The third patient upon whom Prof. Loreta performed his operation of digital divulsion of the pylorus, died of collapse in thirty-six hours. The case was almost hopeless, however, before the operation was begun.

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.

SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MAY 5, 1883.

LEGISLATION AS TO COLOR-BLINDNESS.

THE question of color-blindness in railroad and steamboat employés continues to be a living and very lively issue, between scientists and humanitarians on the one side, and politicians and thousands of their "constituents" (or *voters*), who object to being regulated, on the other. Dr. Jeffries and his co-workers, not only have to fight hard for every inch of advance, but find it no easy matter to hold the ground that they have gained. Two States only have been subdued, and the enemy have succeeded in abolishing the law in Connecticut, and are now advancing in force upon Massachusetts. The following list of questions addressed by the counsel representing the employés, before a Committee of the Massachusetts Legislature, to railway managers, will show the position taken:

"First, Is not a thorough and practical examination of employés for color-blindness and other defective sight on the signals in actual use a sufficient test for such qualifications?

"Second, If an employé is able to discriminate all forms and colors used in your signals, and is competent in all other respects, do you not consider him qualified for railway train service?

"Third, is not the pecuniary interest of railway corporations in the safety of their passengers and trains an inducement for them to be certain of the ability of their employés to distinguish signals?

"Fourth, In your judgment is there a necessity for periodic examination of regular employés for color-blindness or defective sight?

"Fifth, What, if any, accident has occurred on your road, or to your knowledge elsewhere, by reason of color-blindness or defective vision."

It has been shown so often that a color-blind person may, under favorable circumstances, make very correct guesses at the color of these flags and lanterns, by means of the difference in the *intensity* of light in which they appear to him, that the subject seems almost too trite to be mentioned. A red light will appear darker than a green one to a red-blind person, while a green one will appear darker to a green-blind. "Every modification of the intensity of the light is, for the color-blind, a change in color," and may enable him generally to decide correctly, particularly as to familiar objects. This is well illustrated by the case of an engineer, who, when tested with flags in a room ninety feet long always answered correctly, but when the flags were taken to a greater distance outside, where they could be seen from a window, and the red one was placed in front of some foliage, unhesitatingly pronounced it green. Holmgren pointedly asks, if any railroad president would be willing to take the responsibility of running a train if the condition of his sight were such that a feeble light meant danger, a medium one caution, and a strong one "road clear." What is needed, is the quick and certain perception of colors that only normal color-sense can give.

As to trusting to the voluntary action of railway corporations—if the fact that not one in the country paid the slightest attention to the subject until stirred up to it by Dr. Jeffries, were not a sufficient answer, some of their unguided efforts in this direction would make it complete enough. When Dr. Carmalt showed his orders to the President of the New Haven and Northampton Railroad, he was informed that the employés had all been carefully examined by the assistant superintendent, and there was not a color-blind man on the road. Dr. Carmalt, however, proceeded with his work, and found nearly double the average number of color-blind. It was found in Connecticut that complaints were as loud and numerous against the "flag and lantern test," as against the methods of the scientific enthusiasts; and the legislature, not succeeding in devising a test that would meet with the approval of those who failed to pass it, ended the discussion by abolishing the law.

As color-blindness is in a large majority of cases congenital, and when it occurs as a symptom of disease is usually accompanied by other defects of sight, periodic examinations, with reference to it alone, may be much less essential than the original testing. But railroad men, like the rest of mankind, are certainly subject to diseases resulting in color-blindness and also in those defects of vision which entirely unfit them for their work; while,

unlike those engaged in many other occupations, the engineer may keep his secret locked up in perfectly normal-looking eyes until it manifests itself in disaster. A man who applied at the Wills' Hospital with optic atrophy had scarcely vision enough left to drive a cart through the streets in daylight, but had been running express trains, filled with hundreds of confiding passengers, at night, until he could no longer bear the strain of mental anxiety, and was relieved at his own request. It was enough to make each particular hair stand on end to hear him tell of his experience.

The assertion that no accident has, in this country at least, been positively known to have resulted from color-blindness, is considered a very strong argument. We have not been advised as to just how many crushed victims must be unmistakably offered, before it will be in order to take measures to prevent further sacrifices; but it would seem that, to an unbiassed mind, it would be sufficient to show that such things are not only possible, but highly probable. The papers recently reported the case of a man who was frozen to death while driving on a bitter cold night, but reached home without damage to horses or wagon, and with the reins clutched in his stiffened fingers; still, a nervous traveller would scarcely care to trust a driver of that kind. The statement, however, that no accident can be proved to have resulted from color-blindness is not correct, as can be shown, in one case at least, by the following extract from the report of the Railroad Commissioners of Connecticut for 1881: "A few years ago, a collision occurred near Norfolk, Va., between the tugboat Lumberman and steamship Isaac Bell, resulting in the loss of ten lives. A coroner's inquest was held, without definite result; the general impression being that one or the other of the pilots was drunk. There could be no proof of this, however, and the pilots were released. The pilot of the tugboat Lumberman was examined by the surgeon of the Marine-Hospital Service during the current quarter, and found to be color-blind. A rumor has reached the Marine-Hospital Bureau that the pilot of the Isaac Bell is also color-blind." Mr. Thos. F. Wilson, in a communication to the Chicago *Railway Review*, states that he has kept a record of accidents to trains and vessels for some years, and gathered all the information he could in reference to them, and is convinced that a large proportion of them were the results of color-blindness. There is good reason to believe that the famous Norwalk disaster was due to the same cause. It was proved to the satisfaction of the jury and of all concerned that the engineer looked for the signal and thought he saw it; and, in the entire absence of any other plausible theory, it has been thought that he mistook the green foliage of a cedar tree, trimmed nearly to the top, for the red ball that it was customary to display when the draw was closed. This same engineer had met with a serious accident several years before, and after subsequently meeting with several minor mishaps, he put an end with his own hand to a life that seemed to him to be the sport of an adverse fate. Is there not a high degree of probability that two minutes with Holmgren's worsteds would have prevented all this tragedy?

The Massachusetts Legislature passed a law in 1881 compelling railroad companies to have their employés examined for color-blindness and other defects of vision, and requiring re-examination at least every two years. The law did not define the test, but the worsteds have been used. An effort is now being made to induce the Legislature to forbid the use of any other tests than railroad signals, and to do away with re-examinations. The committee to which the subject was referred has reported against the former proposition, but in favor of the latter. Even should the action of the Legislature be favorable, however, it must take the chances of a veto, which the well-known ocular defect of the present Governor makes more than probable.

INHALATION-TUBERCULOSIS.

GREAT stress is laid by those who favor the view that tuberculosis is an infectious disease, upon the results of the so-called inhalation experiments, priority in which is claimed by TAPPEINER, of Meran, who first made them in 1877. Recently, in consequence of Spina's failure to give them due consideration in his work on tuberculosis, Tappeiner has republished his results in an open letter to Spina (*Wiener med. Presse*, March 18th). Tappeiner says that in his first four experiments he used sputa from fresh tubercular cavities, rubbed up with a good deal of water into a thin emulsion, and permitted dogs to inhale it from a steam atomizer, the animals being enclosed in airy cages and protected from dust.

Tappeiner does not describe the exact method and conditions of the remaining experiments, but made in all 31 inhalation-experiments with dogs, of which 18 were true infection experiments with tubercular sputum, 8 control experiments with other substances, and 5 experiments with tubercular sputum, with a view to determining the period of incubation. In all the 18 experiments the results were positive; in 17 there was tubercle in both lungs and pleura; 4 times in addition to the tubercles in the lungs there were tubercular nodules in the kidneys, spleen, and liver, and in 3 instances in addition to the tuberculosis of the lungs there were also cheesy foci and small cavities; in one instance, only, there was typical disseminated desquamative pneumonia.

Of the 8 control experiments, 2 were made with calves' brain treated in the same way as the tubercular sputum; 2 with the suppurative expectoration of a chronic bronchitic patient, and 4 with cheesy pus from lymphatic glands. All of the 8 control experiments were completely negative, there being no trace either of tubercular nodules or of irritation of the lung by the finely divided particles.

In the five control experiments in which sputum from tubercular cavities was inhaled, the animals were killed in 10, 13, 14, 19, and 20 days after the beginning of the inhalation, and none of them showed any trace of tuberculosis or other symptoms of irritation of the lung, although larger quantities of sputum had been inhaled. From these experiments, Tappeiner concludes that the period of incubation cannot be less than 20 days, and since, also, all the dogs killed in more than 24 days from the beginning of the experiments, except the single one with desquamative pneumonia, were tuberculous, it would appear that the inoculation effects developed themselves within the short period of 4 days.

The results of these experiments favor the view that tuberculosis is an infectious disease, but less conclusively than at first appears. For, in the first place, the control experiments are not numerous enough; and secondly, the material used was not in all instances of the right kind to satisfy the essential conditions. The results would have been more conclusive had calves' brain, or similar substance, been used in each instance. For in view of the fact that much of the expectoration in tubercular phthisis is bronchitic, in view of the difficulty of being absolutely certain that the cases of bronchitis from which the sputum is derived are not also tubercular, and in view of the fact that cheesy lymphatic glands are regarded by most morbid anatomists as tubercular, it is evident that all sources of error are not excluded by Tappeiner. Tappeiner does not state whether the tubercular sputum was taken from cavities after death, or whether from the expectoration of those in whom cavities were diagnosticated by physical exploration.

If these experiments could be repeated, and they should be, with due regard to the conditions named, it would seem that their results would have to be regarded as almost conclusive.

THE EFFECT OF QUININE AND SALICYLIC ACID ON THE EAR.

KIRCHNER (*Berliner klinische Wochenschrift*, p. 49, 1882) has studied the effects on the ear of those medicaments which cause dulness of hearing, tinnitus, etc. He finds that quinine and salicylic acid cause hyperæmia of the *membrana tympani*, and of the whole labyrinth, and this congestion may be so intense as to cause hemorrhagic extravasations. In this position, Kirchner is in accord with Dr. Roosa, of New York, who, as is well known, maintains that quinine has a very injurious action on the ear and eye, by reason of the vaso-motor paresis and consequent hyperæmia.

There are, however, two sides to this question. Thus, Weber-Liel, in connection with Gruber, has experimented on adult males with gramme doses (fifteen and a half grains) of quinine. They have ascertained that the temperature of the external auditory canal has been lowered, as also the general temperature of the body. They have not observed any hyperæmia of the *membrani tympani* or other parts of the ear. On the contrary, they have witnessed in five cases the disappearance of a slight degree of hyperæmia, which had existed previous to the administration of the quinine. They ascertained, also, that the maximum degree of impaired hearing was coincident with the greatest decline in temperature.

These observations, so exactly opposed, can be reconciled only by reference to the effect of the dose. Unfortunately, this important factor has been often overlooked. The quantity administered has an unmistakable effect on the results produced. This action may be formulated in a single sentence: Small doses stimulate the circulation, large doses slow the heart and raise the tension. Small doses of quinine cause hyperæmia of the ear, large doses have the opposite effect—causing contraction of the vessels and anæmia. The importance of this distinction is most obvious. As all the world knows, quinine is not the only remedy acting thus; opium, pulsatilla, ipecac, etc., similarly differ in effects according to the quantity administered.

There are other facts which throw a brilliant light on this question. Large doses of quinine, as Knapp and others have proved, cause a marked degree of anæmia of the retina, so that, finally, only the largest vessels remain visible. As these cases usually recover, the condition of the retinal vessels must be that of strong contraction.

THE RIGHT TO MAKE AUTOPSIES IN HOSPITALS.

IN THE MEDICAL NEWS of March 17, we drew attention to an English decision on this point. We were not then aware of any American case, but it seems that one was decided in 1880, in the Ohio courts.

Dr. Wm. Carson, of the Cincinnati Hospital, was prosecuted by a Mrs. Farley, for withholding the dead body of her husband, and for making a post-mortem examination upon it, without her consent. Damages were laid at five thousand dollars. The defence alleged that the incision—it was a case of abscess of the liver—was made during life, but

moved the arrest of the case from the jury, as, even if the allegation were true, there was no violation of any legal right, and no cause of action could accrue.

Both Court and counsel agreed there were no precedents to guide them, but the Court granted the motion on the following grounds. While the taking of the clothing of a corpse is larceny, there is no right of property in a corpse itself. Even admitting that the defendant did injure the body, it is an injury for which there is no legal redress; especially as it was shown that only the purest and best motives actuated the defendant.

An appeal was taken, and the Superior Court sustained the decision of the lower Court, though on somewhat different grounds. The duty as well as the right of a wife to bury a husband's body is recognized by the law, and this carries with it the right to its possession in a fit state for burial. The allegation that the body was withheld was not sustained, for the patient died in the night, and the widow was notified by seven o'clock A. M., and the body was delivered on application. The post-mortem examination if made, as alleged, did not disturb the decency of death. "The privacy of the examination, and the confidence involved in the relation of the defendant as attending physician, freed the act from all indignity. It was not a mutilation of the body, or dismemberment or removal of any part or organ; and for all the purposes of fit and proper burial, the body was left without disfigurement. The right in the widow to possession for those purposes was not, therefore, infringed upon." The Court held that the lower Court should have directed a verdict for the defendant upon the evidence, rather than have taken the case from the jury.

We have referred to the case at some length, since it is of very great practical importance to hospital physicians, and it behooves them carefully to note the points involved in the decisions.

THE CONTROVERSY OVER THE CODE.

ONE of the saddest phases of the Code controversy now waging in New York is the personal feeling evoked. We are the more pained at this development, since it has led to the public expression of bitter animosity in quarters, where we had every reason to expect that only the most fraternal feelings existed. At a recent meeting of the "New Code" advocates, the proceedings of which we find reported in the *New York Herald* of the 21st of April, 1883, one of the speakers characterized the action of a colleague at the late meeting of the Academy of Medicine, as "a disgraceful, abominable trick, and only fit to be undertaken by a low, ward politician." He further stated that "for the rest of my life, I can only treat Dr. ——— with required civility." The offence committed consisted in the introduction of a resolution into the Academy, which, in general terms, may be stated as having for its object the maintenance by the Academy of its own by-laws, including the National Code of Ethics. It was further charged that the meeting of the Academy was packed with the friends of the National Code.

We are deeply grieved that a member of a liberal profession should feel compelled to use such expressions against a colleague, and we urge now upon all parties the exercise of forbearance. Honest differences of opinion should be permitted without questioning the motives of those who entertain them. Whether one's adhesion be to the old or to the new Code, his position is entitled to respectful consideration, and vituperation will not weaken it.

There is another aspect of this controversy which should not be overlooked. The New Code is very explicit on the impropriety of physicians permitting their opinions on medical questions to be placed before the public through the medium of reporters or interviewers, yet its advocates apparently do not feel bound any more by it than by the National Code, and they freely place their views on the controversy at the disposal of the daily papers. On the other hand, we are happy to observe that the upholders of the National Code, with a due regard to the dignity of the profession, have uniformly refused to allow themselves to be interviewed by newspaper reporters. This agitation in public of a purely medical controversy is extremely harmful to the best interests of the profession. The newspapers find in it material for the amusement of their readers, and they serve the morning meal of news and scandal, spiced with choice bits from the "doctors' war." In the language of General Grant—"let us have peace"—outside of the profession, if not in it.

ENTERPRISE IN BUSINESS.

No one objects to enterprise in business until it runs riot, when it is right that it should be checked, and that, too, somewhat sharply. Circulars are issued by the ton praising this or that preparation, or pill, or infant's food, or purgative water, or disinfectant, and each is quickly made remunerative by the endorsement of various doctors and ministers, whose signatures are a supposed guarantee of its worth.

Two classes of doctors sign such papers; first, well-known good-natured men, with weak moral spines, who advertise the medicine, and secondly, ill-known, worldly-wise men who are advertised by the medicine. There is nothing more common than for physicians to sneer at the readiness with which clergymen lend their names to every medical

circular that is presented to them. The day for such sneers has gone by. We live in glass houses.

The last circular (only of course "to the medical profession") is made more obnoxious than usual by the lithographed signatures of four well-known New York medical men, four also well-known Philadelphians, and six irregulars, also equally divided between the two cities. The majority of these men do not need advertising. Why, then, should they place themselves in such an undignified and unethical position as to allow their names to be used by a commercial firm for its own profit?

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, April 10, 1883.

THE PRESIDENT, T. M. MARKOE, M.D., IN THE CHAIR.

RUPTURE OF THE TENDON OF THE QUADRICEPS EXTENSOR CRURIS ON EACH SIDE.

DR. L. A. STIMSON presented a patient with the following history: the patient is a rather small, spare man, 58 years old, who has always been healthy. Ten years ago he slipped while walking, fell backward to the ground and found himself unable to use his right leg. He had broken the tendon of the quadriceps apparently at its junction with the patella. The knee became at once painful and swollen, and he remained unable to walk for four weeks. During the following six months he walked with a cane, and noticed disability of the limb when going up or down stairs, finding himself unable to support his weight upon it when the knee was partly flexed. After the expiration of six months he discarded the cane, and considered the limb about as good as ever; he could carry a load of fifty or seventy-five pounds upstairs in the usual way, taking the steps with each foot alternately, and not aiding himself with his hands. He says the appearance of the knee differed from what it was before the injury: that there was a depression above the patella, and the anterior edges of the condyles were prominent.

Three years afterwards (1876) he broke the tendon of the left quadriceps by a similar slip and fall backward. It was treated in the Chamber's Street Hospital by rest in bed, with the limb bandaged upon a posterior splint. The knee was swollen and painful for three weeks, and more or less stiff for six months afterwards. Then he resumed work as a porter, and worked steadily until January, 1883, his right leg being all this time stronger than the left. His duties frequently required him to carry loads of fifty or one hundred pounds on his shoulder; in walking, he kept the knee almost perfectly straight, and occasionally he fell heavily, this happening whenever he slipped and bent the knee. In going up and down stairs he always aided himself with his hands on the banisters; he says he was always fearful lest he should fall, yet he carried weights, and even climbed ladders. He could not rise from a sitting posture without aid, unless the seat was so high that the knees were extended.

Early in January, 1883, the right knee-joint suppurated, from unknown cause, and he entered Bellevue Hospital. The joint was opened in the median line above the patella, drained, and immobilized. The discharge ceased about the end of February.

His present condition is as follows. Left knee: when the knee is flexed nearly to a right angle, the anterior surface and edges of the condyles are very prominent, and the patella lies below, leaving a deep sulcus above it, between the condyles, occupied only by skin and cellular tissue; this skin is rather closely bound to the condyles so that it does not move upward as freely as the patella. The patella can be raised from the condyles, and the finger passed between it and then from above to the distance of nearly an inch by pushing the skin before it. The quadriceps is atrophied to such an extent that the femur seems almost subcutaneous in front.

The power of active extension is entirely lost. Even when the leg is hanging straight down, with the knee slightly flexed, the foot cannot be moved forward in the least, except by swinging it.

Right knee: still somewhat swollen, and the soft parts indurated. The patient says that its appearance before the suppuration in January last, was almost exactly the same as that of the left knee. The quadriceps is not so completely atrophied as the left, and the patient says the right has been the better limb of the two.

He walks now with one crutch, taking short steps.

DR. R. F. WEIR said that he had just finished treating such an injury in a very heavy man who tumbled in the usual way without striking his knee, but the rupture was different from that illustrated in Dr. Stimson's case. He had met with two varieties of ruptures: one, where the tendon is torn entirely across; and the other, where only the central portion is ruptured. In his recent case, the central portion was involved, and by drawing the muscle down by strips of rubber adhesive plaster, and immobilizing the joint, he was able to get a very good result; that is, the patient was able to throw the leg forward and go upstairs without difficulty. He had seen, a few years ago, one case in a woman where the tendon was apparently divided completely across, but there was some power of extension, showing that it was not entirely separated.

In cases of ruptured quadriceps, attempts had been made to reunite the parts by sutures under antiseptic precautions, but the results had not been sufficiently encouraging to warrant us to repeat the operation. Better results and greater security had been obtained by immobilizing the joint with the posterior splint.

DR. YALE had seen a case in which the tendon had been torn and the patella dislocated laterally by the limb being caught between a cask and the side of a house. The use of the limb was impaired as long as the gentleman lived. The patella, however, made for itself a new point of adhesion at the side of the joint, and the condyles were exposed by so much as the patella had been displaced by the dislocation.

DR. POORE remarked that he had already reported a case to the Society, in which rupture of the quadriceps had taken place, and the separation was four inches, which was finally reduced to about three inches. The rupture was complete. The ultimate result was that the patient had perfect use of the limb; flexion and extension, and walks without a limp.

EPITHELIOMA OF THE EYELIDS, NOSTRIL, AND SIDE OF THE FACE.

DR. GERSTER presented a patient, 64 years of age, illustrating the final result of the removal of an extensive epithelial cancer, which had its commencement at the outer canthus of the right eye. The disease had gradually, in the course of several years, involved the upper and lower eyelids, and the entire conjunctiva, a considerable portion of the superior maxilla, and the cheek and the right nostril. When the patient first came under his observation in September, 1881, Dr. Gerster, with a great deal of difficulty, succeeded in

exposing the eye, and found the cornea ulcerated and in part covered with cicatricial tissue. The patient was entirely unable to move the eyeball, and Dr. Gerster suspected involvement of the orbital tissue and fat. The patient insisted on getting rid of this offensive, ulcerating mass, and when Dr. Gerster had made the necessary incisions, entering the orbit, he found that the tissues occupying the posterior portions of the orbit were not involved at all. The case therefore was not so hopeless as it seemed to be apparently before the orbit was opened. The eye, all the orbital fat, a portion of the superior maxilla, of the skin of the cheek and forehead, both eyelids, and a portion of the right nostril were removed. The defect following the operation was enormous, and it was very incompletely repaired by the process of cicatrization and contraction, and finally, in January, 1882, he proposed a plastic operation, with a view to remedying as far as possible the disfigurement. To do this, he raised two large flaps from the forehead, using one for the formation of the lower eyelid and cheek, and the other for the formation of the right nostril. He cut both flaps intentionally in an oblique direction in order to make them as long as possible. A small part of the flap out of which the nostril was formed, sloughed on account of the pressure of the adhesive plaster plug placed in the newly formed nostril, which, however, looked very satisfactory.

Having obtained union of the two flaps, he still had considerable redundant pedicle. The redundant part of the pedicle used for the nostril was separated three weeks after the former operation and being attached by sutures to the skin of the forehead, served to form an upper eyelid. This subsequently was drawn deep into the orbit, thus forming a sort of lining of the roof of the cavity, and the cicatricial traction thus exerted had the effect of smoothing off the unseemly protuberance caused by the rotation of the pedicle. The redundant tissue of the other flap was also cut away, and put back into the defect caused by its original removal, where it helped to hasten the final healing of the wound. The ghastly deformity having thus been reduced to a small granulating space occupying the apex of the orbit, the patient is enabled to get along well with the aid of a small bit of black silk placed over the orbit as a protector. As yet, the disease had not returned.

DR. WEIR then read a paper entitled

SOME REMARKS ON BICHLORIDE DRESSING.

(See page 491.)

DR. GERSTER said that he had used ligatures prepared after Kocher's method, by the use of oil of juniper, almost exclusively since September, 1882, and in not a single case had suppuration undoubtedly been caused by the ligatures. As far as manipulation of the material so prepared was concerned, it was very agreeable to handle. It is hard and firm, especially if it has been kept for some time in ninety-five per cent. alcohol, which apparently has the effect of toughening the substance; it ties very nicely, and it is not absorbed too soon. He had used it for ligating the large vessels, and with excellent results. As a suture, it answered very well, and lasts longer than the carbolized suture of Lister.

He had also employed Brun's gauze in the German Hospital, the Mt. Sinai Hospital, the German Dispensary, and in private practice. The original method of preparation by the use of alcohol as a solvent made the material very expensive, and with the coöperation of the druggist, he finally succeeded in finding an excellent solvent in benzine, which during the last four years he had been using exclusively. Contrary to what was at first suspected might occur, the benzine had not affected the skin unfavorably; and the cost of the gauze prepared in this way was very considerably less.

DR. WEIR remarked that he had made experiments four years ago with benzine as a solvent, and had found, in corroboration of the statement made to him by Dr. Squibb, that the evaporation of this solvent was so rapid that it carried off with it an undue amount of carbolic acid, held in solution; therefore, the gauze and jute prepared with benzine very rapidly deteriorated, and it gradually fell into disuse in the New York Hospital and other institutions where it had been employed.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

Eighty-fifth Annual Meeting, held at Baltimore, April 24, 25, and 26, 1883.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, APRIL 24TH.—FIRST DAY.

THE Eighty-fifth Annual Meeting of the Medical and Chirurgical Faculty of Maryland commenced in Hopkins Hall, Baltimore, on April 24th, at twelve o'clock; the President, DR. WM. M. KEMP, in the Chair.

After an opening prayer and the reading of the minutes of the previous meeting, the PRESIDENT, DR. WM. M. KEMP, gave the

ANNUAL ADDRESS.

After a brief introduction he spoke of the two lines upon which, from its very incipiency, medicine as a science has run—(1) the line of theory; (2) the line of observation of facts. He proceeded to show how the most important epochs in the history of medicine, when the science made the greatest advances, were periods when men have busied themselves chiefly with the careful and accurate study of facts, and have drawn their conclusions from results thus obtained. He further illustrated his point by reference to individual cases, showing how all real observation of fact has a permanent value which largely depends upon the freedom which the mind of the observer has from servile adherence to the opinions of men of great authority. No advance can be made without a proper independence of thought.

Now that the advantages offered him are so much greater than they were fifty years ago, there is far less excuse for the young medical practitioner failing to become an intelligent physician, able to think for himself, and deserving a worthy place in the profession, able even to advance it. Although after his course of study has been completed he must practise for a little while in accordance with the views he has gleaned from his college, from hospital practice, and from text-books, he should commence independent study with his first case and go on adding year by year to his resources, not only by study, but by observation.

Dr. Kemp thought that, had there been a more thorough understanding and knowledge of the crucial tests, made as to the value of vaccination as a preventative against smallpox at the time of its first introduction, of the best testings during the last fifty years, and a thorough study of their own cases by those who had any considerable experience in vaccination, the doubts thrown upon its efficacy during the last winter would have been met by much more concordant answers, and answers of such a kind from the profession as would have set the public mind more at rest.

But, notwithstanding the wonderful accuracy which is attainable by man, there are two things which should serve to keep him humble—first, his inability to grasp

all the facts within his reach, so that a fresh observer a thousand years hence will still find fresh facts to observe; and, second, the absolute limitations of his knowledge. He can study life, electricity, etc., but remains in complete ignorance as to what they are. It is well for us to recognize these limitations, and to let our studies have the ennobling influence of filling us with a true humility, and with a true reverence for Him who knows it altogether.

Whatever a man's capacities or learning may be, whatever be his creed, there is still in him a restless longing after something higher and better. "We see not in this life the end of human actions. Their influence never dies." "Every morning when we go forth, we lay a moulding hand on our destiny." "In this world, character is in its formative state: it is a serious thing to think, to speak, to act."

REPORTS OF OFFICERS AND COMMITTEES.

After the address, routine business was resumed, during which the following items of interest were brought out: DR. W. F. A. KEMP, the *Corresponding Secretary*, proposed that the executive committee be instructed to take measures toward the reviving the county medical socities in Maryland, there being now but few.

The report of the Treasurer, DR. JUDSON GILMAN, showed the finances of the Faculty to be in good condition.

He also reported, as *Chairman of the Publication Committee*, that 500 copies of the last year's *Transactions* had been printed and widely circulated.

The *Committee on Memoirs*, through its Chairman, DR. H. M. WILSON, presented brief memoirs of Dr. W. G. Regester (who, at the time of his death, had been for twelve consecutive years Recording Secretary to the Faculty), Drs. Charles Albert, Henry Albers, and E. Cleveland Coxe, speaking in warm eulogy of them all.

DR. I. E. ATKINSON, *Chairman of the Library Committee*, reported that the constitutional amendment adopted last year by the Faculty, providing increased funds for the library, while it had not proved such a great success as had been hoped, had been of very great benefit, and that, even now, the library alone formed one of the chief advantages offered by the Faculty to its members. The present number of volumes in the library is 3,346, an increase of 277 over last year. One hundred and eight journals are taken —fourteen English, six French, three German, three Austrian, and eighty-two American.

Some articles of antiquarian value have been added in the shape of some valuable old portraits, and the first volume of the *Baltimore Medical and Surgical Reporter*, edited by Tobias Watkins, 1808, which was the first medical journal in Maryland, and the third in America.

The most important part of their report was that they had received an offer from Dr. J. S. Billings, of the library of the Surgeon-General's Office, in Washington, to take the old books from the Faculty's library that are not owned by the Washington library, and give in exchange double the amount of new books of which they have duplicates (*i. e.*, two new books or pamphlets for one old book or pamphlet). As there are between one hundred and fifty and two hundred old books in the Faculty's Library which could be so disposed of, and which are of no use here, the Committee proposed the following resolution, which was adopted:

Resolved, That the Library Committee is hereby empowered to negotiate with the authorities of the library of the Surgeon-General's Department, U. S. A., for the exchange of books and pamphlets, and to make such exchanges as, in the opinion of the Committee, will contribute to the welfare of the library.

The Committee spoke of the need for increased accommodation for the books.

The Reports of the Sections in order were then taken up.

SECTION ON SURGERY.

DR. OSCAR J. COSKERY, *Chairman*, reported on

LATE ADVANCES IN ABDOMINAL SURGERY.

He confined his report to abdominal surgery exclusive of gynæcology, choosing only gastrostomy, splenectomy, and nephrectomy.

Gastrostomy has been made most successful since the suggestion of Mr. Howse, that the process should be divided into two stages: first, opening the abdominal wall, and stitching the stomach to it by six or eight sutures; and, second, opening the stomach itself five or more days afterwards. A number of cases of gastrostomy, undertaken for various causes, were then given, and Dr. Green, of Bath, was quoted: "On referring to the medical literature of gastrostomy, I find sixty cases of gastrostomy recorded (nearly all of them in the London *Lancet*); eleven for the removal of a foreign body from the stomach; of these, ten recovered rapidly, and one died." This presents a striking contrast to the fatality of gastrostomy performed for malignant disease, the cause being that, in the former cases, the patients were in good health, and had not been subjected to the debilitating effects of cancerous cachexia and slow starvation. In corroboration of this, out of seven cases where the operation was performed for traumatic stricture of the gullet (all patients being under twenty-two years of age), two died—one on the twelfth and one on the twenty-seventh day—from inanition. These last cases do not show an advantage for Howse's operation over the old method, the operations being divided between the two, and the results being the same. In malignant diseases, however, we find his method the most successful. Of twenty-two cases by the old operation, twenty died within the week. Of twenty by Howse's method, one is vaguely stated to have died ultimately; nine within two weeks; three lived two months; one was going on well the ninth day; one discharged from hospital, doing well, on the thirtieth day; three more were living four or five months after. Dr. Green added a successful case of his own.

DR. COSKERY referred to Ashhurst's tables of ninety-seven cases, of which nineteen recovered, temporarily at least, and seventy-six proved fatal in periods varying from a few hours to three months. He had collected further statistics, raising the number to one hundred and three, with seventy-seven deaths, and twenty-four recoveries. He thought also that the prolongation of life for three months in cases of cancer was really a success for the operation.

Conclusions.—1. Gastrostomy, in its widest sense, is a justifiable operation (*a*) where there is a foreign body in the stomach, when for any reason it cannot pass the pylorus; (*b*) in cases where malignant disease or contraction of the œsophagus is progressing; (*c*) where decrease in calibre of gullet is due to inflammatory action after introduction of corrosive liquids, where it will not yield to bougie treatment. 2. The earliest possible opportunity must be availed of for the operation. 3. Incision into the stomach should not be longer than one-eighth of an inch, unless made for the removal of a foreign body, and then as small as will permit of its extraction. 4. It is most successful when performed for the removal of foreign bodies or accidental stricture of the gullet. 5. When done for obstruction to the swallowing of food, the oper-

ation should be divided into two stages, as suggested by Mr. Howse.

The operation of resection of the pylorus, Dr. Coskery thought, was hardly within the pale of legitimate surgery—at least, it was still *sub judice*.

Splenectomy should always be regarded from two standpoints—whether for the removal of an injured or diseased spleen, or for removal when the enlargement is owing to leucocythæmia. A number of instances were reported, with the conclusion that in the former case it is one of the most successful; in the latter, one of the most fatal of abdominal operations.

Nephrectomy is an achievement of the last twenty years. A large number of cases of this operation were quoted, with the following conclusions: We are constrained to consider the operation a justifiable one. The chief difficulty is to make a correct diagnosis between those conditions of the kidney requiring extirpation in the one case, simple tapping in another, or cutting down upon and extracting a stone from the pelvis in a third.

By making the incision in the same direction as for colotomy, the operation should be as bloodless and as free from danger. When the latero-abdominal incision is made, we run about the same risks that the gynæcologist runs in a case of monocular ovarian cyst. The principal dangers in the operation seem to be any accidental adhesions and the shock consequent upon the removal of so important an organ. The method should be left to the individual operator.

SECTION ON PRACTICE.

DR. R. H. THOMAS read a paper entitled

A CONTRIBUTION ON THE INFLUENCE OF SEASON AND WEATHER ON THE DIPHTHERIA DEATH-RATE IN BALTIMORE.

Diphtheria has been endemic in Baltimore since the end of 1860, in which year it first makes its appearance upon the mortality returns of Baltimore.

Dr. Thomas regretted that it was impossible to obtain the number of non-fatal cases in the city, for the deaths bear no permanent relation to the number of cases; still the number of deaths furnish a clue to the number of severe cases.

Up to the end of 1878 the official reports gave only the number of deaths per month. Since then we have weekly reports. The difficulty of the investigation is increased by our knowing neither the date of attack, nor, within a week, the date of death. It is important to bear in mind also that even if the weather, etc., do exert a direct influence, the concurrence of other local causes will produce fluctuations independently of it. For example, other things being equal, a child attacked in a well-arranged house where there are no other children, if it be rigidly isolated, may cause no more cases; but if the disease break out in a crowded tenement-house, one case may prove a focus for a great spread of the disease. Still, before we allow that the season or weather exerts a positive effect upon diphtheria, we must insist in regard to the season, that the curve of diphtheria bears a fairly constant relation to the season or months as they recur, and that the exceptions are comparatively few or unimportant, and, in regard to weather, that the exceptions are few or only temporary.

The writer had decided not to unite the returns for diphtheria and croup, although he himself was disposed to consider them identical; there are still too many who do not so consider them.

From a diagram, he had prepared, Dr. Thomas proceeded to explain the average curve in the diphtheria death-rate in Baltimore for the last twenty-two years. The fewest deaths occur in July. There is a rapid and steady rise from this month, till the highest number is reached in October. During the next two months the maximum is nearly maintained. January shows a commencing fall, which is increased in February, after which there is a gradual fall, broken by temporary rises in March and May until the level of July is again reached. In comparing the separate years with this curve, July was found lowest, or as low as the lowest on the list in fourteen years, eleventh in one, seventh in one, eighth in one, and sixth in three. July shares the lowest figure once with April and June, once with May and June, and twice with August. Besides this, the lowest occurs twice in March, three times in April, once in May, and once each in June and August. The lowest for the year is never met between August and the succeeding March, and with two exceptions not till April. The rise in the death-rate occurs with great regularity after July. In seventeen years, every month thereafter has a larger diphtheria death-rate than July. In the remaining five years the exceptions are mostly unimportant, occurring chiefly in August, though sometimes in the other months, as December.

In fourteen years the highest number of deaths is found in the last three months of the year, in the other years it is distributed between January, February, March, April, and September, never occurring between April and September.

Comparing the years, month by month, January almost always shows a fall from the height attained in the three preceding months; February a fall on January in fourteen years; March has no constant relation to February; April has fewer deaths in fifteen years; May and April nearly correspond; June shows a fall on May in twelve, and July a fall on June in fifteen years. After this the rise is regular, August is more than July in sixteen years; September than August in eighteen; and October than September in thirteen. After this the months nearly correspond. Both on the diagram and year by year, September shows an equality with January, and August with February (the number of times one of these months exceeds its companion month being counter-balanced by the number of times it falls below it). Thus we have a very slow fluctuating fall in the spring, and a rapid rise in the autumn.

This season-curve agrees fairly well with results obtained by other observers who have believed that the season exerts an influence. The season does not seem to exert so great an effect on epidemic diphtheria, though Dr. Airy found the greatest number of outbreaks in England occurred in October. It is interesting to note from this that neither heat nor cold alone can be blamed; but that the rise is most rapid, and the maximum reached at the very season when fungoid growth is most active.

Dr. Thomas proceeded to explain the combined charts which he had prepared, giving the diphtheria death-rate, the average barometric pressure, the total rain-fall, the direction, maximum, and mean velocity of the wind, average thermometric measurement, relative humidity, and approximate degree of cloudiness for every week from the 1st of January, 1879, to the fourth week in April, 1883.

The conclusions arrived at from these charts were as follows: While the total rain-fall for the year, as shown by a table he had prepared, seemed to exert no regular influence, the distribution of the rain appeared to have a good deal. A continued and heavy rain-fall occurring at any one time was followed by a rise in diphtheria. This was specially noticeable when the rain-fall occurred during the summer and autumn. No connection could be found between great cold and great humidity, though unusual heat for the time of year

combined with humidity appeared to act as predisposing causes.

Dr. Thomas' conclusions were as follows, though he explained that they could only be accepted as tentative, and pointing the way for future investigation:

1. While the weather alone does not regulate the absolute number of deaths from diphtheria, it seems to have a very important bearing upon the rise and fall of the violence of the disease, although temporary fluctuations occur independently of it.

2. Temporary changes in the weather have but little effect, but a continued prevalence of certain kinds of weather does cause a rise or fall in the mortality from diphtheria.

3. The conditions favorable to a rise are low barometer, long prevalence of low winds, especially from the east (E., S.E., N.E.), high temperature (for the time of year), with high humidity, and heavy or continued rain-fall.

4. The conditions favorable to a fall are high winds (if not from E., N.E., S.E.), low humidity with high temperature, or high humidity with low temperature, and (generally) high barometer.

These conclusions apply to Baltimore; it is quite likely that in places under other conditions different results would be found. A number of authorities were quoted and discussed. The charts showed no relation between cold and dampness, and the death-rate from diphtheria.

Wednesday, April 25th.—Second Day.

Dr. B. Barton Brune read the report of the

Section on Materia Medica and Chemistry,

giving the most important advances in urinary chemistry published during the past year. He referred to Dr. Garrod's views, that the uric acid is found in the kidney in the form of urate of ammonium; that in the presence of excess of sodium salts it becomes converted into sodium urate, in which form it exists in the blood.

Dr. Garrod does not think that gravel in the urine is the nucleus of a calculus, which he believes to be due to the perversion of the kidney cell secretion, and the action of some colloid matter.

Dr. Brune proceeded to speak of the picric acid as a test for sugar, which has been so warmly advocated by Dr. George Johnson (*Brit. Med. Journ.*, March 12, 1883). His conclusion was that if all Dr. J. claims for it be found true by other observers, this will soon supplant *all* the other popular tests for sugar; but Dr. Brune thought Dr. J. underestimates the importance, as a source of error, of the formation of picrate of potassium when picric acid and a solution of potassium hydrate are boiled together. In a certain number of experiments made by himself, he found that the appearance of such a deep orange discoloration as would seriously complicate the detection of minute quantities of sugar. Dr. J. does not mention, moreover, what effect, if any, the presence of ammonium or some of the iron salts, etc., would have on the accuracy of this method, although these are known to reduce picric acid.

Dr. J. R. Ward, *Chairman*, read the report of the

committee on sanitary science,

in which he urged the importance of more thorough popular instruction on hygiene and the laws of health. The physician ought to avail himself of every suitable opportunity to explain and enforce them amongst his patients. It is likewise most important to impress them upon children and young people, and instructions on hygiene should form part of the regular curriculum in the public schools. The need of such teaching is felt when any contagious disease attacks the community; as, for instance, in the recent epidemic of smallpox in our own city. Dr. Ward then proceeded to speak of the two methods of vaccination, that with bovine virus and that with the human crust. After instancing some objections to which both kinds are liable, he said that the whole subject demanded a much fuller investigation than had yet been given it.

Section in Ophthalmology, Otology, and Laryngology.

Dr. A. Friedenwald, *Chairman*, presented a report on the

relations of spinal and eye diseases.

After speaking of the close connection between ophthalmology and the general practice of medicine, he continued: It has long been realized that spinal diseases not infrequently affect the eye. Not only is this the case with tabes dorsalis, but with other lesions of the cord. Sufficiently large statistics are still wanting upon which to base a correct estimate as to the percentage of eye troubles in affections of the spinal cord. In consulting statements made on this point, we must remember that the optic nerve not seldom presents the first symptoms of the disease. According to Charcot, amaurosis may be the first and for a long time, even ten years, the only symptom manifested. Cyon found eye disturbances in 105 out of 203 cases of locomotor ataxy. Erb says that permanent eye troubles arise in from one-fifth to one-third of all cases, and temporary difficulties in more than one-half; Tropinard, that visual disturbances occurred in 49 out of 102 cases. Not only in locomotor ataxy, in which the eye is most frequently affected, is this the case, but eye disturbances occur also in multiple sclerosis of the brain and spinal cord, in chronic myelitis, in slow compression of the cord after injuries, and, more recently, we find that cases of acute myelitis are not free from this complication. Among others mentioned, Rieger and Von Forster have been conspicuous. They have studied extensively the symptoms of insane paralytics, and, by means of post-mortem examinations, have shown that the optic nerve degeneration which accompanied these cases was due not to cerebral lesions, but to disease of the spinal cord—that was concomitant in these cases; for, though meningitis and atrophy of the cortical substance of the brain had existed, eye symptoms were always wanting unless disease of the spinal cord had also been found. In locomotor ataxy and in multiple cerebro-spinal sclerosis, the eye is not assailed in the same way. In ataxy, the optic nerve becomes implicated, and the disease progresses until total amaurosis ensues. In multiple sclerosis, the optic nerve seldom undergoes complete atrophy, and persons suffering from this disease seldom become completely blind. The eye trouble in the former pursues a steady, in the latter a fluctuating, course. In multiple cerebro-spinal sclerosis, the cord and the eye are independently attacked. We are forced, however, to admit that a diseased condition of the spinal cord can induce changes in the distantly situated optic nerves as a direct consequence, especially in cases due to traumatic lesions. This is also shown by the result of physiological experiment, so that, in the present state of our knowledge, we must assume that the injury is transmitted by a vaso-motor disturbance conveyed in the tract of the sympathetic nerve. We must not overlook, however, that Stilling has traced roots of the optic nerve in the medulla oblongata. Cases where the spinal cord has received traumatic injury furnish the most conclusive testimony regarding the optic nerve degeneration being due to the direct influence of spinal disease. Allbutt found eye disturbances in

eight out of thirty cases. They were only present where the disease was chronic. Dr. Friedenwald mentioned the reports of several other observers on this point, in which cases with vascular disturbance in the eye were mentioned, which he considered to have a very important significance, because Von Graefe rejected the idea that optic nerve atrophy directly follows spinal disease, from the fact that he had never seen it preceded by hyperæmic conditions pointing to an optic neuritis as the beginning of the eye disease. It is very probable that the atrophy, instead of being the starting-point of the eye disease, is but the consecutive expression of a previously existing inflammation.

The force of Graefe's suggestion has been much shaken, not only by observations with the ophthalmoscope, but also by the investigations of Rieger and Von Forster, who report two cases of chronic spinal disease in which well-marked intercurrent hyperæmic conditions were observed. Dr. Friedenwald proceeded to adduce further evidence in support of the above statements, and to speak of the close connection between the sympathetic nerve and the eye, and to describe the various physiological experiments which Rieger and Von Forster have undertaken.

When the cervical sympathetic was irritated, contraction of the pupil and of the retinal vessels ensued. When the lumbar portion of the cord was operated on, there were dilatation of the pupil and contraction of the muscles. When the dorsal portion was chosen, both dilatation of the pupils and of the vessels occurred. The fact that an irritation of the cord will set up hyperæmic conditions of the optic nerve is satisfactorily established, and it cannot be denied that the sympathetic nerve may, under certain circumstances, be the medium through which the eye is reached. Speaking in regard to the differential diagnosis of optic disease as a result of spinal lesions, he said that the ophthalmoscope alone is hardly sufficient. Red and green color-blindness, the contracted field of vision, especially the sector-shaped defects, are prominent among the data furnished by examining the functions of the eye; also increased sensibility to light, even when almost blind. Examination of the tendon reflex will often be of great value. In regard to the changes in the pupils, there is nothing peculiar when they are dilated, but, when contracted, quite a characteristic condition is that, while the contracted pupil shows changes with the efforts at accommodation, it shows no change under the action of light. The most difficult point in this study relates to the disturbance of the external muscles of the eye. The muscles supplied by the fourth pair of nerves enjoy almost entire immunity; those supplied by the third and sixth are attacked with about equal frequency. Sometimes the motor oculi of one eye will be involved, while the abducens of the other alone has suffered. We are still very much in the dark as to this point, and it is hoped that future investigators will clear up the discrepancies.

DR. H. CLINTON MCSHERRY read a paper on

STENOSIS OF THE LARYNX,

illustrating it by three cases from his own practice, one of which he exhibited. The first case was a female suffering from constitutional syphilis. She came to him with a history of chronic trouble in her throat, which, with fluctuations, was getting worse. He found her breathing very labored, and, on laryngoscopic examination, the whole larynx pale, the arytenoids being very much enlarged and œdematous, but showing no sign of phthisis; ventricular bands so much thickened and broadened that on attempted phonation they met together. The voice was a muffled whisper; on deep inspiration the edge of the right vocal cord came into view, the left could not be seen. Throat symptoms apart, her general condition was good. Considering the thickening to be due to syphilitic perichondritis, he relied upon local applications and constitutional treatment; applied iodo-glycerine (Vienna Hospital formula) daily, with excellent results; galvanism to the larynx being also used. To the second case he was called in haste, on account of impending suffocation. This also was trouble of a specific nature; the laryngoscope revealed complete destruction of the epiglottis, and inflammation of the ventricular bands, which were so swollen as to hide the vocal cords. The glottis was so closed as to be not larger than the calibre of a goose quill. Other means having failed, laryngo-tracheotomy was performed, after which the patient did well. Having reduced the thickening in the glottis by means of local applications of a solution of cupri sulph. for two weeks, Schrötter's dilating tubes were daily introduced, size gradually increased for a month, with good results. After accustoming the patient to breathe through the natural openings by frequently corking up the tracheal tube and continuing the above treatment for nearly a year, he was able to remove it entirely and close the wound. This patient was exhibited. There is no difficulty of breathing, though the voice is still a little husky.

Dr. McSherry proceeded to give a *résumé* of the course pursued by typical cases of different kinds of laryngeal stenosis. His opinion was that although most cases of stricture of the glottis are due to syphilitic disease, constitutional treatment alone will never effect a cure in a well-marked case; local treatment being always necessary. Tracheotomy is proper to save from imminent death, but should not be undertaken without laryngoscopic examination, as the dyspnœa may be caused by a slight œdema glottidis or a collection of mucus. Schrötter's hard-rubber tubes are invaluable for dilatation. Speaking of the mode of dilating the larynx after tracheotomy, he referred to an instrument for dilatation from below (through the tracheal opening) invented by Störk in 1878, which Dr. McSherry had so modified as to give it three dilating blades instead of two. These blades may be made of different lengths to suit different cases, and may be gradually more and more separated from each other day by day, by turning a screw outside of the canula to which the instrument is fastened; the third blade is placed anteriorly, so that as they separate, the blades form a triangle, which is the normal shape of the larynx. Dr. McSherry then exhibited this modified instrument; he then described Schrötter's method of dilatation after tracheotomy, and other instruments for dilating the larynx. Dr. McSherry considered that the cases he had reported illustrated the good results obtainable in laryngeal stenosis.

DR. C. W. CHANCELLOR read a paper on

THE SEWERAGE OF CITIES: LIERNUR'S PNEUMATIC PLAN.

It is as important a matter for cities as for individuals to get properly rid of all waste and effete matters. Liebig tells us that every living organism produces in its offal the manurial ingredients, both quantitative and qualitative, required for reproducing the means of sustaining its life. So it is also undeniable that the nitrogenous and other matters in the sewerage of cities might be so used as to suffice for producing food for the people of the city. But this fact is ignored. We import fertilizers at great expense, when we have them at hand, and use what we have to pollute our streams. Considering the so-called "dry systems" out of the question, Dr. Chancellor spoke of the three great systems: 1. "The English water carriage," or "combined" system, found throughout England, and in many large cities of the

Continent. This treats all sewerage of all kinds alike, by conducting them off in the same conduit, a large quantity of flushing water serving as means of conveyance. This system Dr. Chancellor condemned. The principle "that water is the cheapest carrier," is wrongly applied. It is true in the case of navigable rivers and canals, but not for sewers, where enormous quantities ot water must be supplied from the city water works, especially when the offal must subsequently be again removed at great cost. Again, as the maximum water use is in the morning, and the least at night, the sewer flood is in the daytime and the ebb at night. During the ebb the sewer becomes "coated" with fecal slime about one twenty-fourth to one thirty-second of an inch thick, which is not removed by flushing, and enters into putrid fermentation soon after being exposed to the air, as it is every evening. This fermentation is a fungous vegetation of the most dangerous kind. Sewer ventilation does not prevent these fungoid growths from exerting their poisonous influence, for being solid, they cannot be diluted by the air, and they cannot remain suspended. As a matter of fact, sewer gas does find its way into dwellings.

The chief difficulty with this system is what to do with the sewerage matter after it leaves the city. Empty it into the nearest water-course? Then the rivers, bays, etc., are hopelessly polluted, as is notably to be seen in the Bay of Naples. Use it for irrigating land? This is altogether inapplicable to large cities. The land becomes overdosed, and a noxious swamp results, as has been seen near Berlin. Only rank grass thrives on such diluted manure, and it is almost worthless. In short, this has proved a failure. The failure of this led to the second system, called the "separating" system; this is open also to serious objections, and having two sets of sewers on this plan really doubles the danger.

In Baltimore, with its numerous hills, the surface drainage should be as little as possible interfered with, as every rain aids in keeping the city clean; only short, shallow conduits in certain parts of the city are needed for the removal of rainfall.

The third, or pneumatic system of sewage, as invented by Capt. Liernur, a distinguished engineer of Holland, was next considered. This system was inaugurated by him when he was intrusted with preparing plans for the drainage of the fortifications of Luxemburg. His instructions were that only inoffensive waters should drain off into the little stream (Else) on which the city is built, and that all matter suitable for manure, should be preserved for that purpose. He adopted the plan of having two distinct sets of sewers, one for matters which are essentially dangerous from a sanitary point of view, but which have sufficient value as manure to justify the adoption of processes to render them available for agricultural purposes; the other for fluids already inoffensive, or easily rendered sufficiently so to be discharged directly into the nearest water-course. Dr. Chancellor proceeded to describe with much minuteness the pneumatic system, how the sewers of each kind were constructed, and how they worked, together with their special advantages. The advantages possessed by the water sewers are: 1. That it does away with the expensive collecting or intercepting sewers for conducting the sewage in mass to some common outlet away from the city. 2. With all expensive fixtures for flushing, such as water galleries, tanks, grates, etc., there being nothing to demand removal by extra flushing, or to cause a nuisance at the outlet. (No solid matter greater than a fraction of an inch in size being allowed to enter.) 3. With all expensive structures for entering and lighting the sewers for the purpose of removing sedimentary deposits, since no deposits are formed. Another advantage is that the household drains enter the sewer in such a way as to create a current forward in the fluid in the sewer. The result is: 1. All water entering the sewer is converted into hydrodynamic motive power, pressing as it does on the sewer contents by means of vertical injector tubes in the direction of the flow. 2. (As the sewer is kept full of water,) all inlet arrangements and ventilation tubes are entirely superfluous, there being no air admitted or any to be displaced. Thus an effective self-regulating sewerage for household and manufacturing wastes, is afforded, which discharges them in an innocuous condition, and dispenses with the above-mentioned contrivances used in ordinary sewerage methods. After speaking of some modifications for rain and sub-soil sewerage, Dr. Chancellor proceeded to describe the excretal sewers on the Liernur method. This he went through in detail, showing how simple and yet how perfect the arrangement was, and then explained how this kind of sewage is utilized. All the fluid parts of the matter are driven off by the use of heat, the same fuel being used for this purpose as is employed for working the vacuum engines for the sewers, thus much reducing the expense. As the process takes place in a partial vacuum, there is no smell. The result is that the fæcal matter becomes a valuable commercial article, being reduced to a state of fine powder fully as well suited for manure as is guano, and far less costly, and, at the same time, it has been removed from the city in strict accordance with the laws of sanitation. Notwithstanding the apparent complexity and costliness of this system (which is only apparent) it turns out in the end not only more advantageous to health, but really cheaper than the other systems. Dr. Chancellor concluded by speaking of the necessity for convincing the public that "the present barbarous mode of removing offal, of polluting streams, and wasting millions worth of valuable manurial material, has no longer any right of existence, since sanitary science and engineering skill have fully succeeded in satisfying all demands in reference thereto."

THIRD DAY.

After reading the minutes, the first order of business was the

ANNUAL ORATION,

by DR. JOHN S. BILLINGS, of Washington. After some introductory remarks, the orator proceeded to the discussion of his subject, which was

"MEDICAL BIBLIOGRAPHY."

This was defined as the science of books having regard to their description and proper classification. This definition in the *Encyclopædia Britannica* is very much modified from that of a hundred years ago, when it signified "skill in deciphering and judging of ancient manuscripts," that is paleography. Bibliography, when applied to a particular subject, includes the idea of giving references to all the literature of the subject down even to single paragraphs which furnish information with regard to the matter in hand. The first distinct and separate work on the subject is that of Pascal Le Cocq (*Paschalis Gallus*), 1590. This book is arranged alphabetically by the first, not the last names of the authors.

Israel Spachius published at Frankfort, in the following year, his *Nomenclatura Scriptorum Medicorum*. It contained references to 1436 different authors. Both books were based on the *Bibliotheca*, of Gessner. After describing the *Bibliotheca*, of Haller, the orator proceeded to say that it was not his intention to indicate or comment upon the various systematic works on medical bibliography, but he would

consider, to begin with, some of the methods used in medico-bibliographical work.

1. First there is the old-fashioned way of searching books immediately at one's command, using their indices, noting all references to other works, going to a library, procuring more books and more references, etc. This a very laborious way, though after a while it becomes a pleasure. The best work has been done by this method, but it requires much time. 2. The modern mechanical way, the extreme of which is to pay some one to make a list of references for you, and then print it as a bibliography of the subject, without taking the trouble to consult the works themselves. Some writers seem to desire to furnish their article with an imposing list of references without much caring whether they have special relation to the matter in hand or not. The mechanical method, however, is of great use as saving the time of those who can be more usefully employed, and, in most cases, the mass of material to be dealt with is too great to be handled in any other way. "There is danger," as Sir James Paget says, "that in the multiplication of scientific pursuits, and in the superabundance of means of publication, we shall lose the accuracy which should be at the foundation of our work. The publishing of error is quite as easy as the publishing of truth, and there will always be a large number of persons who will believe a statement because it is in print."

An article, signed Ch. R., in the *Revue Scientifique* for July, 1882, urges sincerity as an indispensable condition in bibliographical work. "It is almost a lie to quote a book which one has not had in his hands." Elementary scientific honesty requires that only such books be cited which one has read. No author can consult everything that has been written upon a subject, but there is nothing to prevent stating that a given bibliographical note is at second-hand, and noting the authority for it. Truth is not the only requisite for good bibliography. An important part of true erudition, as the same writer observes, consists in the elimination of the many useless data and materials that have been collected. M. Richet would have no mention made of such references. Dr. Billings thought that, so far as concerns the titles of books or papers, which might seem to a person unacquainted with them to relate to the matter in hand, this rule was not to be followed; that when a writer has examined such a book or pamphlet, and finds that it would be a waste of time to consult it, either from its want of originality, or from its contents not corresponding with the title, etc., he should note the fact distinctly. It is often as important to indicate "no thoroughfare" as to point out the direct road.

This critical indication of the value of a paper, makes the difference between bibliography properly so called, and catalogues and indexes; the main purpose of a bibliographer being to save his reader time and trouble should he wish to verify or enlarge upon the author's statements. If in his investigations he consult a book which proves to be practically useless, he should spare his reader the trouble of looking it up by telling him so. Of course, it is much easier to refrain from all mention of contemporary works than to speak disparagingly of them; but it should always be done for the older writers when any attempt is made to present a bibliography, properly so called.

M. Richet does not think it unwise to attribute great importance to bibliography, nor does he think the turning over of a great number of pages destroys originality. Those too who have the gift of originality, are excused as being the creators who have no need to be erudite. But the majority, who are neither discoverers nor inventors, do need to be. Prof. Verneuil in his preface to the *Treatise on Gastrostomy*, by L. H. Petit, is more decided in his high opinion of erudition. In his opinion, the author of this book has contributed as much to the future success of this operation as any who have practised it, although he never performed it, and probably never will; the work is one of pure erudition. He says: "Scientific progress is due to three things of equal importance, viz., erudition, observation, and experiment. There is a bibliographical method which is distinct, independent, worthy of cultivation for its own sake, and in no way inferior to its two rivals in the amount and value of the information which it furnishes. . . . While erudition certainly creates nothing, it leads to creation. To discountenance research in literature, is like advising travellers who visit regions not yet fully explored, to refrain from making use of the maps prepared by their predecessors. The great objection to such work is the amount of time which it requires if it is to be done thoroughly and accurately." He proceeds to show how the time spent is greater on account of each man having to serve his own apprenticeship almost alone; for bibliological method has never been taught. No one could do such work for himself on all subjects; a lifetime would not nearly suffice for pathology. While observation and experiment are not to be depreciated, let erudition be duly honored.

In America, Dr. Billings went on to observe, there is rather a feeling of undue uncritical admiration for erudition in bibliographical matter than of the contempt or dislike of which Prof. Verneuil complains in France. Until recently, American physicians had not at their command the means of research in medical literature possessed by their trans-Atlantic brethren, and even now in many places they cannot obtain access to them. The members of the Medical and Chirurgical Faculty of Maryland, especially those living in Baltimore, are peculiarly fortunate in this respect. You have a library in Baltimore, which, until a few years since, had for its strongest characteristic feebleness. Recently, the collection has been put into order, and made accessible, a certain number of medical journals are regularly received, and other improvements have been effected. The best use, however, to which your library can be put to, is so to arrange it that it may be the means of your getting the full benefit of your other collection over in Washington, which you may consider as a sort of branch library of the faculty.

The library of the Surgeon-General's Office is a large and valuable one; it is your library, intended for your use, and not a bureau library intended for the use of officials. How may you best use your two libraries, and what should be done to maintain and increase their completeness and usefulness?

First, then, your library in Baltimore should be made, and kept, as complete as possible in the local medical history of the city and State. It should contain every medical book, pamphlet, etc., published in, or relating to the State. The great majority of these will cost nothing but watchfulness and prompt application for them at the time of publication, but if they be not then obtained, the acquisition soon becomes difficult. You want every report of a hospital, asylum, or dispensary; every announcement or catalogue of a medical school; every mortality report, order or handbill issued by sanitary authorities for the State or city; and, as far as possible, you want to obtain at least two copies of each, one for the Baltimore and one for the Washington branch. It is a matter of interest also to keep in the library, constantly posted up to date, a scrap-book for local newspaper cuttings of all matters of medical or sanitary interest, which should be promptly and systematically inserted. A small scrap-book properly indexed to contain newspaper medical

advertisements, especially those of the various quacks who infest this, as they do all other large cities, will be found in years to come very interesting, and, it may be, useful.

The limited amount of funds available for increasing your Baltimore collection, will naturally be, for the most part, applied to the purchase of medical journals. The main thing which you have to do is to perfect the system of care and storage of your books, in order that they may be perfectly secure against, let us say, unauthorized borrowing.

This is necessary, not only to preserve your own books, but to make it possible for the Washington library to loan freely to the Baltimore library. The Washington collection is a reference, and not a circulating library. It does not, as a rule, loan books to individuals; although for modern books which can be readily replaced it will do so upon a sufficient deposit to amply cover their value, its rules in this respect being the same as those of the Library of Congress; but it will freely loan them to other libraries which are so constructed, located, and managed that the books in them are secure from fire, theft, etc. Now suppose that a member of the Faculty desires to prepare a somewhat elaborate article upon some medical subject for a society or journal, and that for this purpose he wishes to compare his own experience and observations with those of others, how is he to proceed?

Before attempting to answer this, Dr. Billings remarked that, as the librarian is busy with his current work, it is impossible for him to assort and arrange references to any great extent in answer to letters from physicians, although he can of course furnish information requiring some half dozen references, can verify a quotation, and is glad to furnish information which a brief examination of a few volumes will supply. The doctor had better visit Washington himself and examine the references, cards, etc., which he can do if he does not interfere with the catalogue work.

Secondly. As a rule it is not well to issue a circular informing the world at large of one's intention and asking physicians generally to report at once all the cases they may have had of the particular disease or injury which one proposes to discuss. This may properly be done by those recognized as authorities on the subject, and who may well be trusted to classify, compare, and judge of the results of other's work. But when a comparatively unknown man makes such a demand, his success will probably be small, and properly so. A man must show he has money before calling on the public to bank with him. To obtain as much as possible from a library, you should bring as much information there as you can, and have it in as clear and definite a form as possible. Note upon a slip of paper the books you wish to see, giving their titles concisely but clearly, so that they may be easily found. Consult the *Index Catalogue* so far as published, the *Index Medicus*, and the bibliographies attached to the articles in the modern French and German encyclopædias, and it will be strange if you can find no titles which will put you on the right road. Remember that the *Index Catalogue* is not a bibliography. Dr. Billings said that he might some day have occasion to write on its uses and abuses, in which case the main point would be that it must be used for a time before you can judge of its merits.

Having prepared the list of references to be consulted, which had best be written on cards of uniform size, the next thing is to get the books. A visit to Washington, when possible, is the best thing; much time will be saved if a list of the books desired be sent by mail to the librarian the day before the visit, so that they may be laid out ready for examination. Where a personal visit is impossible, the best thing is to get a library which has means of safely caring for the books, and will be responsible for loss or damage, to borrow them, the applicant, of course, paying the expenses.

At present it is a part of your duty also to see that your Washington library is made and kept as complete as possible. In the first place, it should have every new medical book, journal, report, or thesis, in every language, as soon as possible after its publication. You ought to be certain of finding in this our national medical collection the latest literature upon any subject connected with medicine; and everything noted in the Index Medicus should be upon its shelves. Now, to effect this would require an appropriation of from seven to eight thousand dollars a year. The medical journals and transactions relating to medicine and the allied sciences will alone cost about $2,500 per annum. In the second place, the deficiencies in the library should be gradually supplied as opportunity offers. The amount and character of these deficiences are a matter of some interest. In order to obtain some data on this point, I have compared the catalogue of the Washington Library with those of the two largest collections of books in existence, viz., the British Museum of London and the Bibliotheque Nationale of Paris. Taking the fasciculi of the catalogue printed by the British Museum in 1881–82, I find that, on 1,140 pages, containing about 34,000 titles, exclusive of cross references, there are the titles of 657 books and 880 inaugural theses relating to medicine. Comparing these with the corresponding portions of the Washington Catalogue, it is found that the British Museum has 262 medical books, 372 medical theses, and 118 different editions which are not in the Surgeon-General's Library. On the other hand, the Surgeon-General's Library has 285 books, 342 theses, and 88 different editions which are not in the British Museum. There are common to both libraries 277 books and 508 theses. The two libraries, therefore, appear to be nearly equal as regards medical books. This is exclusive of medical journals, transactions, and reports in which the Washington Library is much the richer. The following tables show in detail, by countries and periods, the difference between these collections as regards medical books:

The Catalogue of the Medical Section of the Bibliotheque Nationale in Paris, is arranged by subjects and not by authors, does not include inaugural theses or dissertations, and was published in 1857–73, hence it is not possible to make an exact comparison between it and the *Index Catalogue*, or that of the British Museum. But taking the general subjects, anatomy, diseases of the eye, and cholera, I have prepared a table showing the results of a comparison of the two catalogues, from which it appears that in the first three subjects named, 199 books are common to both, 416 are in the Washington collection only, and 483 in the Paris collection only. On the subject of cholera (excluding treatment), 194 books are common to both, 745 are in the Washington Library only, and 272 in the Paris Library only. The books which the Paris Library has, and our own Library has, are not for the most part old books, dating before 1800, or French books which come to the Library, under the law which requires one copy of every French publication to be deposited there.

This law is not strictly obeyed, for we have in our Library 79 French works on cholera, which are not in the Paris Catalogue—but it is due to this law that the Medical Section of the National Library of France, is essentially French and not cosmopolitan.

As the result of these comparisons, I think it is safe to conclude, that the Library of the Surgeon-General's Office in Washington not only contains more medical literature than the British Museum or the National

Table giving results of a comparison of 1140 pages of the British Museum Catalogue in the letters A and C, with the corresponding pages of the Index Catalogue of the Library of the Surgeon-General's Office, U. S. Army, Washington, D. C.

NOTE.—Theses and reprints excluded.

Library of France, but that it covers a wider field, represents better the medical literature of the whole world, and is decidedly a better practical reference and working collection for medical purposes than either of the great libraries referred to. Each library is, as might be expected, richer in the literature of its own country, but the French Library is comparatively poor in English and German medical books, and has almost nothing in American medical literature, while the English Library is also poor in American literature, and comparatively weak in German medicine of the present century. Both of them are rich in the literature of the fifteenth and sixteenth centuries, and have many editions of older works, of which the Washington Library has only one or two. Both of them have been in existance for over three hundred years, and have had almost unlimited funds for the purchase of books.

Why, then, is it that they do not contain all medical books which have ever been printed, and that your medical library in Washington, which is only about twenty years old, and has never had in any one year funds sufficient to purchase more than two-thirds of the medical books printed in various parts of the world during that same year; should already be equal if not superior to them in practical value? It appears to me that it is very largely due to the fact, that while the Washington Library is the national collection, it has been kept separate from the general national library. The result of this has been, that the medical profession has taken much more interest in it than they would do

if, as is the case with the English and French medical collections, it was merely a section of the National Library.

As a matter of fact, comparatively little use is made by medical writers of the collections in the British Museum or the Bibliotheque Nationale. They consult, in preference, the special medical libraries in London and Paris, which are under the direction of medical bibliographers, such as the libraries of the Royal College of Surgeons or of the Medico-Chirurgical Society, or those of the Faculty of Medicine or of the Academy of Medicine of Paris. It is to such special libraries that physicians give their books and pamphlets; and the rapid growth of the Washington Library is largely due to this cause. There is pouring into it a steady stream of literature, the sources of which are by no means confined to this country, although, of course, the largest part comes from the United States.

Those who incline to pessimistic views of human nature, and to attribute all the actions of men to selfish motives, would not find their views confirmed by my experience. I could name a number of gentlemen who take almost as much interest in the library as if it were their own, and who are constantly on the lookout to supply its deficiences.

Now, so long as the library can preserve and extend this feeling of interest in its completeness, so long it is sure to grow in value and usefulness; but if it be merged into a general national library, this interest will rapidly diminish. It is not to be expected that the manager of a large miscellaneous library, if well fitted for his position by a knowledge of general literature, should also be familiar with the various departments of scientific literature. As the modern Greeks say, "two watermelons cannot be carried under the same arm," and no subordinate or assistant will have the same stimulus to do good work that the man who is responsible in the eyes of the public will have. I think, therefore, that you will do well to see that a proper and commodious fire-proof building is provided for your Washington collection, that it is not merged with the Congressional Library, and that it is granted sufficient funds to enable it to secure all new medical books as they are published, and gradually to collect the best of the older literature.

It is supposed by some that this library receives a copy of every medical book published in the United States. This is not the case. Under the copyright law, two copies of every copyrighted medical book are deposited in the library of Congress, but no copy comes to the library of the Surgeon-General's Office. It seems to me that the law should be so amended as to make our library the place of deposit for one of the copyright copies, and this is a matter to which I invite attention. The keeping of this library complete is one of the most valuable means of advancing medical science in this country, now in our grasp, and it is within our grasp if the medical profession of this country choose to exert their influence for this purpose. The opportunity now presented for placing this matter on a proper and permanent basis will not occur again. There are not two springs in a year, nor in the life of a nation, and if the spring work be not done in time, the fruits of summer and autumn will be correspondingly deficient.

Dr. Billings said he liked the quaint, old-time name "Medical and Chirurgical Faculty of Maryland." While all real universities have other faculties, as of law, theology, and so forth, the term "*The Faculty*," applies only to medicine. This meaning of the term originated in Paris, where those who graduated as doctors graduated as teachers also, and the Faculty was composed of all the graduated doctors of medicine of the university. Thus the faculty of physic alone of all the other faculties of the university formed not only a corps for instruction, but also a body exercising a liberal profession, of which they had the monopoly, lucrative and honored, accessible as a rule only to the upper middle classes, and brought into continual relations with the public. Thus it came to be known as "The Faculty." Let the Faculty of Maryland preserve not only the name but the best of the tradition, such, for example, as that the doctor be an educated man, as his name implies. It is to be hoped that the higher medical education which the university is soon to organize will include instruction in bibliographical and historical methods. This will make the Washington library a very important aid to the university and prove a stimulus to the Baltimore collection.

Section on Gynecology and Obstetrics.

Dr. Wm. T. Howard, *Chairman*, made a lengthy report, illustrating his subject by stereopticon views thrown on the screen. He spoke of a number of gynecological operations, and concluded by a strong argument in favor of Tarnier's forceps.

This was followed by a supplementary report from the

Section on Materia Medica and Chemistry,

by Dr. Jno. T. Lynch, who read a paper entitled

Observations on the Antipyretic Effects of Carbolic Acid; and on the Astringent Influence of Rubus Procumbeus in Diarrhœa and Dysentery.

He said that, having had his attention called to the remarkable effects of carbolic acid in lowering the temperature in and apparently shortening the duration of enteric fever, by reports in the London *Lancet*, he had, during the past three years, experimented largely with this substance. He would not, however, go into the details of the cases treated, though he could speak of several hundred, but would briefly give the results of his observations. In his early experiments, the dose used was small, but it was subsequently increased, until, finally, as much as five grains was given every two or three hours, and thus far no toxic effect had ever resulted from these large doses.

The formula now used is:

Acidi carbolici, . . .	ʒj.
Tr. aconiti rad., . . .	ʒss.
Glycerini, ...	q. s. ad ʒjss.

Sig. Teaspoonful every two, three, or four hours, according to the temperature.

The tincture of aconite root was added as a heart sedative, as the carbolic acid did not seem to possess this quality. Dr. Lynch said that he had used these doses in all kinds of fevers, and found them fail less frequently than any other antipyretic, except the cold bath. It seemed to be precisely in those cases which quinine fails to control that carbolic acid is most effectual and reliable. Of this, Dr. Lynch mentioned a striking case, and added that, in purely inflammatory fevers, it does not show such complete control over the fever temperatures as in the purely idiopathic or essential ones, though it is still very useful. In enteric or typhoid fever, it seems especially applicable, preventing diarrhœa and tympanites, depriving the fecal discharges of the characteristic fetid smell, and, above all, entirely preventing the secondary fever. It also cuts short the disease. In septicæmic fever, too, the acid seems to act with a certainty and energy far superior to quinine. Dr. Lynch then gave in detail a case in which the two drugs were successively used, the carbolic acid contrasting favorably with the quinine.

On the use of *Rubus procumbeus*, Dr. Lynch re-

marked that, although many of the old-fashioned remedies had given place to drugs and extracts containing the same active principles, they were sometimes far from producing the same satisfactory results. In his own experience, he had obtained most excellent results from the use of fluid extract of dewberry root in obstinate diarrhœa during phthisis, and also in the summer diarrhœa of infants. It has an effect far surpassing tannic acid, and seems to act as a specific. He has lost no case from the summer diarrhœa of children since he has used this drug.

APRIL 27.—FOURTH DAY.

DRS. H. NEWELL MARTIN and LEWIS T. STEVENS read a paper on

THE DIRECT ACTION OF ALCOHOL UPON THE HEART.

The authors experimented with the heart of the dog, isolated from all of the body but the lungs, in the manner previously described by one of them. The heart was nourished with defibrinated blood, then blood containing one-eighth, one-quarter, or one-half per cent. of absolute alcohol supplied to it, and finally good blood again. They find:

1. Alcohol in the above doses has no influence on the pulse-rate.

2. As regards the work done by the heart in a minute, blood containing one-eighth per cent. of alcohol is without effect, at least for five or ten minutes; but blood containing one-quarter per cent. of alcohol nearly always, and that containing one-half per cent. always greatly diminishes the work done. If the supply of alcoholized blood be not too long continued, the heart can be recovered by feeding anew with pure blood.

3. The diminution of work is due to an alteration in the elasticity of the cardiac muscle, in consequence of which the heart swells out, so that even in its systole it nearly or quite fills the pericardiac bag. Hence, in diastole, it cannot dilate further to receive a fresh supply of blood.

4. If the pericardium be removed, the above doses of alcohol are without effect on the work done, at least for a considerable time; the heart, however, swells enormously, and beats in a quite unphysiological manner, never obliterating its ventricular cavities in systole.

In a paper on

SOME FORMS OF LARYNGEAL PARALYSIS,

DR. J. D. ARNOLD described two cases in his own practice. The first case was that of a young lady, æt 19, who had for three years suffered from almost total loss of voice supervening on a severe attack of diphtheria. Faradism and galvanism with strychnia given subcutaneously in medium doses, had been persisted in for fourteen months without any manifest improvement. On examination with the laryngoscope, Dr. Arnold found the larynx normal in development and healthy in color and contour. The excursions of the cords and arytenoids were natural in amplitude, but upon attempted phonation, the left cord remained nearly immovable, whilst the right advanced slightly beyond the median line. After various experiments, Dr. Arnold found that upon touching the intra-arytenoid space with the tip of a sound, short isolated coughacts were produced, at which times the cords met in the middle of the glottis for an instant, and further, he found that the cough so produced *had tone*. He diagnosed a case of functional paresis, perhaps of an hysterical nature, and not of true diphtheritic paralysis. The patient appeared in robust health, so the treatment used was merely local. He applied a very weak faradic current four times a week, which, with short intermissions at intervals of ten or fifteen seconds, was applied for ten and twenty minutes, and immediately afterwards the intra-arytenoid space was lightly brushed with a delicate elastic whalebone sound. Each touch occasioned a sudden flying together of the cords, succeeded by the violent expiratory act of cough. After three weeks of this treatment, she acquired the power of giving tone to the vocal *a* (German inflection), and so, little by little, regained the whole range of vocal sounds, so that in less than three months from the commencement of treatment, she could sing as well as speak in a full, clear tone, and the voice had gained all its original compass. Twenty-one months afterwards, she had a relapse after a powerful emotional impression caused by the illness of a brother. This time the loss of voice was not complete, and the attack yielded to a few days' treatment and has not since recurred.

The other case was that of a married woman, forty-five years of age, who had suffered for several years from attacks of sore throat. The last attack had not yielded to the usual remedies, but had grown worse, until her voice was reduced to a whisper, broken occasionally by hoarse, guttural tones. She had also a harassing cough and great pain in swallowing. On inquiry, he found that she had had three healthy children, but during the last seven years had had five miscarriages, and this fact, though unsupported by any other symptoms, induced him to give her the benefit of an anti-syphilitic treatment. The larynx, when first examined, exhibited the following appearance: Epiglottis somewhat depressed and of a deep-purplish color, right arytenoid and ventricular band dusky, but of normal contour, the right cord crimson in hue and slightly thickened. The left arytenoid was swollen to about twice its natural size, and felt firm and unyielding to the sound; the left vocal cord was nearly invisible, and, except at the anterior third, was covered by a red, angry-looking tumor which seemed to spring from the ventricle. There appeared to be no loss of continuity in the mucous membrane anywhere in the larynx. When the patient attempted to phonate, the whole left side of the larynx remained immovable. He was led to suspect that the apparent tumor was in reality a prolapsed ventricle, and was in fact successful in returning it to its place with the sound, when there came into view beneath, the cord, unbroken on its surface but red and tumefied like its fellow. The slightest cough, however, or effort to produce phonation forced the ventricle back to its former position. Dr. Arnold pursued a constitutional treatment in this case, and strictly enjoined disuse of the voice. He also insufflated one-fourth of a grain of morphia with starch (to allay the cough) every day, and immediately afterwards replaced the ventricle, which was always displaced by the cough brought on after the insufflation. The local treatment consisted also in the application to the ventricle of a few drops of tinct. iodine and glycerine in equal amount at each visit. The patient improved rapidly, and in about three weeks was able to speak for some minutes in a low, quiet tone, whilst the larynx had to a large extent regained its normal appearance. In six weeks from the time the case was first seen, he had occasion to replace the ventricle for the last time. She is now almost entirely well.

SECTION ON PSYCHOLOGY.

DR. RICHARD GUNDRY read a paper on

PROGNOSIS IN INSANITY.

He said that certain symptoms render the prognosis absolutely unfavorable. The age of the patient may exercise some influence; youth being more favorable than old age. Insanity of children complicated by epilepsy, etc., is generally incurable. Propensity to suicide in children from apparently slight causes is

seldom suspected until carried into effect; when early recognized, it seems amenable to treatment. In his own cases, the largest percentage of recovery occurred in patients under twenty, the next highest between forty and fifty. Over sixty, the proportion sensibly decreases. While females seem more likely to recover than men, they run greater risks and are more liable to relapses. This is largely due to the incessant cares of a mother in the lower classes and the listless inertia of women in the more comfortable classes. A material influence is exerted on the prognosis by the previous mental training and habits of the patient, whether his mind has been so disciplined as to exercise control over himself and his passions, or whether the emotions have attained mastery. Habits of self-denial and thoughtfulness for others, and strong sense of duty are great aids in the struggle towards restoration. Men of high grade of intellectual capacity suffer less from insanity, and when they suffer recover more readily, and a lofty aim in life has contributed much toward mental health. The earlier treatment is begun, the more hopeful is the prognosis. Hereditary influence does not preclude hope of recovery. A main factor is to be found in the distinction of mental disorder occurring in a previously duly developed normal brain with normal functions, or in a brain with abnormal functions due to inherited predisposition or other morbid constitution. The various periods coincident with physiological development, and so forth, may eventuate the attack. Puerperal mania is generally considered curable and leaves but little trace in cases where some cause is added, which would of itself have produced insanity, as some toxæmic influence or great moral depressing agency. Where the state itself appears to be the cause, the final prognosis is unfavorable. He proceeded to speak of various forms of insanity with their prognosis. Insanity occuring after the normal development of the brain and its functions presents a more favorable point of view. He included in this melancholia, in all its phases, and mania. Acute melancholia, however, is rapidly fatal. Dementia as a primary form is essentially curable; it is difficult, however, to distinguish it from the secondary form, which is incurable. General paralysis of the insane has an entirely bad prognosis. Syphilitic insanity, early discovered, is usually amenable to treatment. Rapid invasion of the disease is more favorable than gradual incubation. A sudden apparent recovery is not so favorable as a gradual return to health. The most favorable symptom is when the patient recognizes that he has been insane.

DR. S. C. CHEW presented

A CASE OF DEXIOCARDIA.

When he first saw the case, he supposed, after a hasty examination, that it was due to a left pleural effusion having pushed the heart to the right side of the chest. On further examination, it was found to be caused by disease on right side of the chest, the heart being carried over by the contraction of the right side after absorption of pleural effusion. The right side measures seventeen inches in circumference, the left eighteen. The lung itself has become affected with fibroid disease, and now contains vomicæ. The heart beats in the right mammary line, or a little beyond it.

The first case of this kind is reported by Dr. Stokes (1841–42).

EXCISION OF SUPERIOR MAXILLA.

DR. F. MCLANE TIFFANY presented a patient, a girl, whose right superior maxillary bone he had excised, removing the bone from the left lateral incisor to the second molar. He said that it was usually the custom, when the whole bone or a large portion of it was to be removed, to perform tracheotomy, and to plug the throat with cotton to prevent suffocation from the bleeding. Tracheotomy was supposed also to lessen the danger of septic poisoning, the breath passing not over the wound, but through the tracheal tube. Billroth has, however, lessened greatly the mortality after operation in the mouth by the use of iodoform, showing that cleanliness is what is needed, and not tracheotomy. Dr. Tiffany had once, in this operation, performed tracheotomy from its supposed necessity. In this patient, he had adopted a different plan. Anæsthesia having been induced by ether, he placed the patient on the face, the shoulders and body projecting beyond the table, and supported by two assistants, and the head supported by a third. When the body is so slung, it does not interfere with respiration. He operated with a lateral light, holding the head towards it. In this way, the blood runs out of the mouth, and suffocation is not induced. The history of the case is as follows: Three years ago, it was noticed that her jaw was swollen. There was no pain, and the swelling increased slowly. For a month before the operation the swelling grew with great rapidity. The bony roof of the mouth was largely destroyed, and the growth was covered over only by mucous membrane. The tumor was elastic to the touch. The operation was done in the position above described. It was now just four weeks and two days since the tumor was removed. The wound had not quite healed, but was healthy and granulating. The microscope showed that the growth was spindle-celled osteo-sarcoma.

In a paper on

SUBCUTANEOUS NERVE-STRETCHING AS A TREATMENT FOR SCIATIC NEURALGIA,

DR. J. W. CHAMBERS said that this operation was first introduced to the profession by Prof. Billroth early in 1882. It consists in placing the patient flat upon his back with the leg extended, the thigh is then strongly flexed upon the abdomen. Dr. Chambers described three cases in his own practice, in all of which a complete cure was effected, and also four other cases furnished by Dr. Coskery and Dr. Jones, of Frostberg, Md., three of which were cured, whilst in the fourth scarcely any improvement took place. He also cited four other cases from the journals, in two of which a favorable result was obtained, whilst the other two were not much affected. From all these cases Dr. Chambers drew the following conclusions: 1. That in obstinate cases of sciatic neuralgia the subcutaneous stretching of the sciatic nerve is highly satisfactory. 2. That from effects produced by the subcutaneous method, it is highly probable that all required force can be obtained. This he had also proved by experiments upon the dead subject. 3. The sciatic nerve could by this method be sufficiently stretched to produce anæsthesia. 4. That moderate elongation of a nerve impairs its sensory, and but little, if at all, its motor functions. 5. That considerable force may be applied to a nerve trunk without seriously impairing its motor functions. 6. That it is not necessary or justifiable to employ more force than just enough to produce anæsthesia.

DR. JOHN MORRIS said that he had seen the operation of nerve-stretching by Dr. R. Winslow once when it was cut down upon and then stretched. This was followed by a perfect cure. Five days before, the subcutaneous operation had been performed on another of his patients. The knee had been brought over so as to touch the abdomen. There had been great pain since, not only from the stretched muscles, but from the nerve below the knee.

DR. CHAMBERS replied that no operation could pretend to cure all cases of a disease. Sometimes cases of supposed sciatica were really cases of neuritis, in

which case no good could have been done. He thought that in Dr. Morris' case the nerve may have been too much stretched. He had found this was followed by pain. In comparing the subcutaneous stretching with the other operation, he said it was much safer, and there was less danger of such great stretching as would cause disturbance not only of the sensory, but also of the motor and even trophic elements of the nerve, as had occurred in the history of the more serious operation, death occurring after sloughing.

DR. G. HALSTED BOYLAND read a paper on

HYPNOTISM,

which considered, 1st. *Its danger;* and 2d. *Its remedy.*

DR. RICHARD GUNDRY said that it should be regarded as a crime for a physician to leave a hypodermic syringe in the hands of his patient. He had seen most disastrous results from this practice.

FIFTH DAY.—APRIL 28TH.

DR. ST. GEORGE W. TEACKLE read a paper on

FACTS RELATING TO THE CASES OF SPONTANEOUS COWPOX IN BALTIMORE CO., AND THE RESULT OF EXPERIMENTS WITH CRUSTS OBTAINED THEREFROM.

He began by saying that he had been requested in last January, in company with DR. J. R. WARD, of Gavanston, to visit a gentleman's farm, to pass an opinion on a disease affecting the udders of his herd of Alderneys. On examining them, he found them to be suffering from cowpox. The four cows affected presented the disease in its various stages. No. 1, first affected, had dried, semi-hard crusts, considerably smaller than when produced by inoculation, but beautifully cupped. Nos. 2 and 3 presented vesicles becoming pustular, and pustules; No. 4, a few papules. The eruption was confined to the bags and udders (mostly the udders). The number of points of eruption was not numerous. The history was that, while thirsty and restless, their appetites were good.

The following facts were elicited: (1) No fresh additions had been made to the herd, except that six months before a cow had been sent to Connecticut, to a celebrated bull, but inquiry showed there was no disease among the cattle there; (2) no disease of the kind had prevailed on the farm; nor (3) had any one there been vaccinated within six months; (4) there was no smallpox patient or vaccine farm within a radius of three miles, nor had any one visited a variolous patient. Dr. Teackle concluded from this that case No. 1 was one of spontaneous cowpox. He had vaccinated, moreover, five primary and three secondary cases with portions of the crust of case No. 1, with two failures (one primary, one secondary). The cases that succeeded were markedly severe in their action, especially in the febrile symptoms, also in the glands.

Owing to circumstances over which Dr. Teackle had no control, he was not able to obtain all the matter from these cows he desired; but having encased some of the crust he had taken at his first visit in wax, he inoculated (April 20th), in the presence of Drs. Stuart and Morris, a heifer, eight weeks old, with it. He felt confident that further propagation of this new stock would cause a return to the confidence in bovine virus, which has recently been sadly shaken.

DR. JNO. S. LYNCH doubted the spontaneous origin of the affection, and thought it most probably had been caused by inoculation of smallpox virus, perhaps conveyed by people who had milked the cows by stealth, unknown to the proprietor. Spontaneous origin of smallpox or vaccinia was unknown.

DR. TEACKLE replied that these cows were kept as carefully as race-horses, and never without an attendant. Such a mode of conveyance as suggested was out of the question.

THE PRESIDENT referred to the fact that, at the time of the discovery of vaccination, and during the experiments which followed it, it was very nearly proved that the discharge from the hoofs of horses in the disease called grease would produce nearly the same effect as vaccinia in the cow. Might not the disease have been conveyed from the horses to the cows by the grooms? On motion of Dr. John Morris, seconded by Dr. Teackle, a committee of five was appointed to examine and watch the course of the vesicle in the heifer presented, and report to a future meeting.

DR. JNO. N. MACKENZIE then read a paper entitled

SOME REMARKS ON NASO-AURAL CATARRH AND ITS RATIONAL TREATMENT.

He commenced by speaking of the great prevalence of the disease in Baltimore, and remarked that it is, perhaps, the least perfectly understood of the prevalent diseases. After giving a very minute description of the disease, which he divided into two stages—first the hyperæmic and second the hypertrophic stage—and describing its various forms very minutely, with their effects upon respiration, phonation, and olfaction, he spoke of its connection with pulmonary emphysema and chronic laryngitis, and expressed his opinion that, under certain conditions, nasal catarrh may favor the development of consumption. He regarded the inflammation of the conjunctiva, so often observed in connection with nasal catarrh, as caused not by the extension of the inflammation, but, in the majority of cases, as a reflex vaso-motor phenomenon. He considered that frequently chronic catarrhal inflammation of the middle ear depended upon the changes induced through the Eustachian tube secondary to chronic nasal catarrh. Morbid conditions of the nose, however, react in another way upon the circulation and nutrition of the aural chambers, viz., through reflex agency of the vaso-motor and trophic nerves.

Dr. Mackenzie emphasized especially the *great frequency* of reflex cough as a symptom of nasal disease, and he has found in the nose a reflex sensitive area analogous to that discovered in the larynx by Störk, etc.

Systematic treatment is a *sine quâ non* for the successful management of chronic nasal inflammation. This may be divided as follows: 1. Removal of all obstructions. 2. Thoroughly cleansing and keeping clean the nasal and retro-nasal chambers. 3. Treatment on general principles of the congested and inflammatory conditions of the naso-pharyngeal membrane. He limited his remarks largely to the question of the removal of the hypertrophied membrane. As a rule, he prefers in this operation the employment of the cold steel wire snare. The operation fulfils in the simplest and most radical manner the chief indication for treatment, which is the removal of obstruction—it restores the respiratory current to its normal channel, and removes the most prolific source of the discharge. In most cases it causes the various complications, especially those of a reflex character, to disappear, and by the depletion of the cavernous cells of the turbinated bodies, it exercises a beneficial effect upon the whole area occupied by the erectile tissue. He then spoke of the second principle of treatment—cleansing—objecting strongly to the nasal douche. He gave several remedies which he had found of value in the treatment of nasal catarrh; among others, diluted alcohol, and weak solutions of bichloride of mercury, and the tincture of galanga, he objected to the use of powders, unless in an impalpable state; where there were excoriations or ulcerations, he had found the powder of calendula dusted over raw surfaces, or applied as a

glyceride, to cause rapid healing and diminution of the discharge. During inclement weather, or when exposed to a vitiated atmosphere, he recommended, when the discharge is not profuse, a respirator of absorbent cotton—medicated or not, teased gently apart in the fingers; this teasing is very important. It is then folded lightly upon itself, and introduced into the nostril just beyond the orifice of the anterior naris. He strongly recommended oakum as a substitute for the cotton tents usually employed; he also advocated constitutional treatment. He then considered the subject of catarrhal otitis media, and concluded by showing forceps of his own device for the removal of adenoid growths. The blades are fenestrated, and slightly flattened posteriorly and superiorly to admit of perfect contact with the walls of the pharynx. Their cutting edges prolonged downward to the shank, are on the principle of the Luer bone nippers; each blade may be used as a curette, the other being fixed. The instrument may also be used for removing growths from the throat, etc.

DR. H. P. C. WILLIAMS read a paper entitled

MALARIAL FEVER IN PUERPERAL WOMEN,

giving an account of three cases. The first, a primapara, after a hard instrumental labor, was delivered of a large child with life extinct. There was laceration of the cervix and rupture of the perineum. Vaginal injections were ordered, and equal parts of tinct. of camphor and belladonna were applied to the breasts to prevent the secretion of milk. After three days the belladonna was discontinued. It was a point of interest that two days thereafter distinct symptoms of belladonna poisoning—dilated pupils, tingling, and the surface of the body becoming bright scarlet and very hot—made their appearance. The symptoms were promptly checked by the exhibition of morphia and potass. brom. Several days after this she had symptoms that at first appeared to point to septic poisoning, but from the regularity of the fever and its wide range, Dr. Williams was inclined to think it malarial. Large doses of quinine, however, did not check it at first, and it was not until six grains were given every second hour, and twelve doses had been administered, that the fever was broken. After this she went on to recovery. Another interesting point in the case was, that though the perineum had not been sewn up after the birth of the child on account of the weakness of the mother, it was found to have been almost completely restored spontaneously.

The other two cases, though not so severe, corresponded with this in the occurrence of fever, that at first seemed alarming as occurring in that condition, but which yielded promptly to quinine. Dr. Williams explained the occurrence of malarial fever on the supposition that, though they all seemed in perfect health at the time of their confinement, the malarial poison was in their systems, and the depression of their vital powers caused it to make its appearance.

REPORTS OF COMMITTEES.

DR. T. BARTON BRUNE, *Chairman of the Committee on Nurses' Directory*, made an encouraging report. A small balance had been turned into the general treasury for the use of the library, as had been ordered by the Faculty. Dr. Brune hoped that the physicians of the city would support the *Directory* to a greater extent than they had done in the past.

The *Committee to Interview the Trustees of the Peabody Library*, in regard to procuring more medical books for the library (Dr. J. J. Chisolm, Chairman), reported that the Trustees had replied that, with the funds at their disposal and with the terms of their trust, they could not procure books for their library for any special branch of professional men, but would be glad to purchase books on medicine that would be of general interest and importance. The Committee was continued to interview the projector of the Enoch Pratt Library on the same subject.

As owing to some mistake the resolutions passed last year reaffirming the faculty's allegiance to the *Code of Ethics* of the American Medical Association had failed to reach that body, DR. WILLIAM LEE moved a similar resolution to be sent to the Association this year, which was adopted.

DR. RICHARD GUNDRY moved "that a committee of five be appointed by the Faculty to represent to the Legislature of Maryland the urgent need of an institution for the care and education of feeble-minded children." Adopted.

On motion of Dr. J. R. Quinan, a vote of sympathy was passed with Dr. J. Shelton Hill, for his protracted illness.

The Publication Committee, in a special communication, informed the Faculty that Dr. J. R. Quinan had in accordance with the request of the Faculty in 1881, prepared a full and complete history of medicine in Maryland, giving biographical accounts of the physicians of the State, and a list of their contributions to medical literature, etc., with a subject index of their writings. The work was described as being very exhaustive—extending considerably over one hundred years. The committee recommended that as the work will comprise over two hundred pages octavo, that it be published separately, as a supplement to the *Transactions*, and that one thousand copies be printed, and a copy given to each member of the Faculty who has paid his dues, and that one hundred copies be given to the author, and the remainder be sold at one dollar per copy to assist in defraying the expenses of the publication. These recommendations were unanimously adopted, except that it was ordered that two hundred instead of one hundred copies be given to Dr. Quinan. The thanks of the Faculty were tendered to the author.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—DR. RICHARD MCSHERRY.
Vice-Presidents.—DRS. W. STUMP FORWOOD and JNO. S. LYNCH.
Recording Secretary.—DR. G. LANE TANEYHILL.
Assistant Secretary.—DR. ROBT. T. WILSON.
Corresponding Secretary.—DR. W. F. A. KEMP.
Reporting Secretary.—DR. R H. THOMAS.
Treasurer.—DR. JUDSON GILMAN.

After a vote of thanks to the President for his able presiding over the meeting, and thanks to the Johns Hopkins University for the use of Hopkins Hall, the Convention adjourned *sine die*.

MISSISSIPPI STATE MEDICAL ASSOCIATION.

Sixteenth Annual Session, held at Meridian, April 4, 5, and 6, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE Sixteenth Annual Meeting of the Mississippi State Medical Associaton was held at the Opera House, in Meridian, April 4, 5, and 6, the *President*, DR. WIRT JOHNSTON, of Jackson, being in the chair.

FIRST DAY. APRIL 4.—The Association was called to order at 11 o'clock, A.M.

After prayer by Rev. Joseph Bardwell, D.D., DR. J. H. BLANKS, *Chairman of the Committee of Arrangements*, introduced COL. W. H. HARDY, of Meridian, who delivered an eloquent and scholarly address of welcome.

The roll was then called by the *Secretary*, DR. T. W. FULLILOVE, and about fifty members answered to their names. During the session twenty-nine physicians were elected members of the Association.

The PRESIDENT, DR. WIRT JOHNSTON, delivered the

ANNUAL ADDRESS.

He congratulated the Association on its substantial growth and flourishing condition, and proceeded to review the work of the Association, which had resulted in the establishment, by legislative enactment, of a State Board of Health, which has been "clothed with ample power, has abundant resources at its command, and is in a position to render efficient service to the State," and also in the law recently enacted to regulate the practice of medicine in the State. "A law," said he, "which, if it should continue in operation, and is wisely administered, is sure, in the course of time, to elevate the character of the profession. It will not only accomplish this, but will also result in even more good to the people of the State, as by it they will be protected in life from the ignorance of the incompetent, and, in purse, from the cupidity of quacks."

He then proceeded to give some interesting statistics, which the operation of the law had developed. Under Section 17 of the law, all physicians of whatever school, engaged in the practice of medicine at the date of the passage of the law (approved by the Governor, February 28, 1882), were granted license without examination by a board of censors, provided the application for license should be received by the Secretary of the State Board of Health on or before June 30, 1882. The law requires each license to be registered, within thirty days after it is issued by the Secretary of the State Board of Health, in the office of the Circuit Clerk of the county in which the licentiate resides. After June 30, 1882, no one could be granted a license without presenting a certificate of having passed a favorable examination by the Board of Censors of the Congressional district in which the applicant resides. There are two Sanitary Commissioners for each Congressional district (appointed by the Governor, on the recommendation of the State Medical Association), who are members of the State Board of Health, and *ex officio* constitute the Board of Censors of their respective districts.

The following are the statistics:

Number of licenses issued under Section 17,	1785
" " " after examination,	55
Total number of registered physicians,	1840

Each licentiate is required to designate, in his application, the school of medicine to which he belongs. This has been done, with the following result:

Regular, 1581; eclectic, 84; Homœopathic, 11; botanic, 7; botanic and eclectic, 4; allopathic and mineral, 5; eclectic and allopathic, 8; mineral, 11; allopathic and botanic, 2; eclectic or reformed, 1; hydropathic, 1; eclectic, allopathic, and Homœopathic, 1; dosimetric, 1; physio-medical, 1; idiopathic, 1; and 121 who either state no school or use obscure expressions.

The ratio of physicians in the State of Mississippi is, therefore, 1 to about every 615 inhabitants.

The President advised the Association to adopt a suitable plan of awarding prizes for meritorious essays, as a means of encouraging original research, and of elevating the literary standard of contributions.

The address was referred to a committee of three, who, after considering the subject, unanimously recommended the appointment of a committee to report, at the next session of the Association, a well-digested scheme of prize essays. The report of this committee was adopted.

REPORTS.

DR. J. M. TAYLOR, of Corinth, Chairman, read the report of the *Executive Committee*, which was received and ordered to be spread upon the minutes.

The *Secretary*, DR. T. W. FULLILOVE, made a verbal report. He stated that he had notified Hon. Frank Johnston and Hon. E. Barksdale of their election to honorary membership in the Association. (The former, a prominent member of the legal profession, and the latter, editor of the Jackson *Clarion* and member-elect of Congress, were elected honorary members during last year's session, as a tribute of recognition of the value of the services they had rendered in advancing the interests of the medical profession in this State.) He read the letters of these gentlemen accepting the honor that had been conferred upon them. Each of them paid, in eloquent terms, a warm tribute to the worth of the medical profession. The letters were ordered to be published in the *Transactions*.

DR. ROBERT KELLS, of Jackson, *Treasurer*, read his report, showing all indebtedness paid, and a balance in the treasury amounting to $364. At Dr. Kells' request, his report was referred to an auditing committee.

DR. B. F. KITTRELL, of Black Hawk, read a report of an interesting case of

CHRONIC HYDROCEPHALUS,

which he thought should be placed on record on account of the large dimensions of the head. The history of the case presented nothing peculiar, the head having begun to enlarge a few days after birth. The child (a negro male) is now in his ninth year. The circumference of the head measures twenty-eight inches, and the distance from ear to ear, over the vertex, eighteen inches. Complete ossification has taken place, except at the anterior and posterior fontanelles, and at a small space in the coronal suture on the right of the fontanelle. The child measures thirty-three inches from the acromion process to the sole of the foot.

DR. B. A. VAUGHAN, of Columbus, read a paper on

VACCINATION,

in which he argued to sustain the following four propositions:

"1st. That vaccination, if perfect and typical, is as protective to-day against smallpox as it was in the days of Jenner.

"2d. That properly transmitted bovine virus, or humanized virus of not over four cultivations, is as perfect in its protection against variola, whether it come from the 'Jenner' or 'Beaugency' stock.

"3d. That vaccine virus, of many human transmissions, is less protective than bovine virus, or the virus of a few removals from the cow, and will not produce typical vaccina.

"4th. That many failures, as well as many varied departures from typical vaccina, so often observed in the two years past, are due to the quality of and manner of collecting the lymph, as well as, in some measure, to climatic and epidemic causes, and not to vaccina pure."

DR. N. L. GUICE, of Fayette, in the discussion that followed the reading of the paper, remarked that he preferred fresh bovine virus, and insisted that the frequent failures in its use were chiefly due to the fact that most operators, forgetting that it is less soluble than humanized virus, do not take sufficient pains to rub it into the abraded cuticle.

DR. JOHN BROWNRIGG, of Columbus, remarked that he would not rely upon bovine virus, when, during the prevalence of an epidemic, he should wish to secure the speedy protection of persons who had just been exposed to the disease. He would certainly vaccinate the infant of a variolous mother with humanized virus.

Dr. R. S. Toombs, of Greenville, had recently used during an epidemic that had prevailed in his vicinity, bovine virus obtained from the farm of Dr. E. L. Griffin, and had been highly pleased with the result, successful vaccinations having been secured in the large majority of instances.

Dr. Vaughan closed the discussion by insisting upon the importance of revaccination in its technical sense, that is, during the progress of vaccina, the virus should be inserted again and again, until it is proved that the subject of the operation is no longer susceptible to the influence of the virus. He also described the typical scar resulting from vaccination with genuine protective virus, and stated that it was vitally important that such a scar should be obtained.

Afternoon Session.

Dr. A. P. Sims, of Morton, presented before the Association, a case of

ARTIFICIAL ANUS

in the person of a negro man, who had received, six years ago, a gunshot wound of the abdomen. The artificial anus was situated in the right iliac region just above the crest of the ilium; this bone was injured, and, during the healing process, portions of it had exfoliated. During the past three years, a portion of what was supposed to be the inverted ilium had been gradually extruded until now ten or twelve inches of the intestine, considerably altered and hypertrophied, were outside the abdomen. The peristaltic motion of the bowel was plainly visible; the orifice, through which the feces escaped, remained at the margin of the wound where the intestine had originally adhered to the abdominal wall.

Dr. S. V. D. Hill, of Macon, read an able and exhaustive paper on

RECENT ADVANCES IN SURGERY,

in which he culled from the broad field of recent surgical achievement what is most worthy of preservation.

Dr. J. E. Halbert, of Leota Landing, read a paper on

MALARIAL HEMATURIA,

in which he stated that he had had a large experience in the treatment of this formidable malady. He sums up his course of treatment as follows: "I first advise prophylaxis; purgatives of calomel in large doses, encouraged by enemata; warm bathing to promote action of the skin; sinapisms to epigastrium—ice, and, if the patient is weak, champagne; carbolic acid, in small doses; digitalis, as a gentle diuretic and heart stimulant; as astringents, gallic acid and ergotine, if the hemorrhage is continuous and exhaustive. In addition, I allow lemonade and bitartrate of potash *ad libitum*, but the sheet-anchor is quinine hypodermically. Nourish by rectum, if necessary, and avoid, if possible, giving medicines, or anything except ice, champagne, and concentrated nourishment by stomach."

Evening Session.

Dr. W. E. Todd, of Clinton, read a paper on

TYPHOID PNEUMONIA,

which gave rise to a lengthy discussion of the general subject of pneumonia, in which Drs. Taylor, Hill, Guice, Sale, McCallum, C. A. Rice, Toombs, Moore, Murry, Vaughan, Ward, Kittrell, and Todd, participated.

Drs. Taylor and Hill objected to the term *typhoid* as applied to pneumonia, because it was misleading in its suggestion of enteric complication. *Asthenic* or *adynamic* was the term which would more properly indicate the true condition. Pneumonia might occur as a *complication* during the progress of typhoid fever.

Dr. E. P. Sale, of Aberdeen, protested against the routine treatment of pneumonia. He would be governed by the indications presented in each individual case: to the one, with hot skin, high temperature, and bounding pulse, he would administer aconite in suitable doses; to another, with cool skin and feeble pulse, he would give stimulants and use means to induce reaction; and to the patient, in whom the disease was simply revealing its natural history, with no special symptoms calling for treatment, he would administer nothing whatever.

Dr. B. F. Kittrell, of Black Hawk, apropos of the question whether pneumonia would induce phthisis, related the history of a case still under his observation, in which a boy (white), seventeen years of age, who had previously seemed to be the incarnation of robust health, had been suddenly seized with pneumonia, which was supposed to have originated in his imprudence the day previous to the attack, when he suddenly cooled his person after becoming overheated by unusual physical exertion. The lower lobe of the left lung was the first seat of the inflammation, which, during the latter part of the second week, suddenly extended to the upper lobe, the whole lung becoming completely hepatized. At first, the disease could not be distinguished by the physical signs from ordinary croupous pneumonia, and its true nature was not suspected until, in the third week, there was no indication of resolution in any part of the lung. At the present time, after more than three months have elapsed, while the right lung has remained free from disease, the greater part of the upper and a considerable portion of the lower lobe of the left lung have undergone caseous degeneration, and a large cavity has resulted. Adhesion of the pulmonic and costal pleural surfaces, and perforation of the intercostal spaces have occurred at two points, with local emphysemata resulting; and there is a free discharge of pus from the lower point (which had been aspirated) between the sixth and seventh ribs, below and to the right of the mamma. The father and the mother of the boy, both over fifty years of age, have always enjoyed ordinary health, but upon inquiry, it has been ascertained that several near relatives on the maternal side have died from pulmonary consumption.

All the speakers, who alluded to the use of opium in the treatment of pneumonia, agreed in regard to its inestimable value.

(To be concluded.)

NEWS ITEMS.

NEW YORK.

(From our Special Correspondent.)

The Code Controversy.—The New York Society for the Maintenance of the National Code of Ethics have now enrolled more than 400 physicians residing in the city.

The society organized to prevent the reënactment of the National Code has just published a list of 205 members, of which there are:

Names not in the *N. Y. Medical Register*	20
Names not in the *Register* and not in the *City Directory*	15
Dentists	2
Veterinary surgeons	2

WHEELING, WEST VA.

(From our Special Correspondent.)

SMALLPOX.—Twenty cases of smallpox have just been discovered in Mercer County, West Virginia, and the State Board of Health has been appealed to for help.

TORONTO.

(From our Special Correspondent.)

THE TWO SCHOOLS OF MEDICINE in this city have closed for the session. Nineteen of the students of the Toronto School of Medicine received the degrees of M.D., C.M., from Victoria University, and over twenty students of Trinity Medical School were successful in obtaining their degrees at Trinity University. A good number from both schools presented themselves for degrees at the University of Toronto, where the examinations in medicine are just complete, but the results are not yet known.

A MEDICAL COLLEGE FOR WOMEN is about being established here, and the announcement of the Faculty will probably be issued in a few days. It will be the first of the kind in Canada, and the promoters have every confidence in the success of the scheme. Already a fair number of students have signified their intention of attending, some of whom have completed part of their course at various colleges. A large number of sympathizers are said to be willing to give liberal contributions towards the endowment of the college.

THE ONTARIO MEDICAL ASSOCIATION is announced to meet in Toronto on the 6th and 7th of June.

THE STATE MEDICAL SOCIETY OF WISCONSIN.—The thirty-seventh annual session was held at Milwaukee last Tuesday. In accordance with the expressed wish of many members, no general business was transacted, but a quorum of the Society met and appointed delegates to the approaching session of the American Medical Association, and the Society then adjourned to a later date, to be hereafter announced.

PUBLIC HEALTH LAW IN WISCONSIN.—The State of Wisconsin has recently enacted a law which makes obligatory:

1st. The organization of a board of health in every town, village, and city in the State, within thirty days after each annual election.

2d. The appointment of a health officer by every board of health within ten days after its organization.

3d. The report of contagious diseases by all physicians.

STATE MEDICAL SOCIETY MEETINGS.—The Indiana State Medical Society meets on the 8th inst.; the Pennsylvania State Medical Society, at Norristown, on the 9th; and the Michigan State Medical Society, at Kalamazoo, on the 9th.

BELLEVUE HOSPITAL MEDICAL COLLEGE.—DR. JOSEPH W. HOWE has resigned his professorship of clinical surgery in Bellevue Hospital Medical College, in the following letter to the faculty, which explains his reasons: "Having been informed that unless I could join with the rest of the faculty in supporting the code of the American Medical Association my resignation would be acceptable, I hereby tender my resignation as Professor of Clinical Surgery in Bellevue Hospital Medical College."

UNIVERSITY OF THE CITY OF NEW YORK.—Dr. J. W. S. ARNOLD has resigned the professorship of physiology in this institution, and Dr. Lewis A. Stimson has been elected to fill the vacancy.

DR. FRIEDRICH AHLFELD.—The Emperor has appointed DR. F. AHLFELD, regular professor in the University of Giessen, to the Chair of Medicine in the Faculty of the University of Marburg.

PRIZE OF 50,000 FRANCS.—The French Government has offered a new prize, to be called the VOLTA PRIZE, for the best paper on the "Application of Electricity to the Production of Heat, Light, Chemical or Mechanical Uses, and Use in Telegraphy and Therapeutics." The prize is international, and will be awarded on June 30, 1887.

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending April 21, indicate that influenza, consumption, and whooping-cough have increased, and inflammation of the brain and diarrhœa have decreased, in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported present during the week ending April 21 and since at thirteen places, scarlet fever at eighteen places, and measles at twenty-two places.

Four cases of measles came with immigrants arriving at Port Huron April 20.

OBITUARY RECORD.—PROF. MAURICE KRISHABER, the eminent laryngoscopist, has recently died, in Paris, of typhoid fever. Thoroughly broken down by constant anxiety during the recent illness of Mme. Krishaber, the shock of her death was too much for him, and he succumbed to the disease which developed in his overtaxed system.

In laryngology, Prof. Krishaber was an original and widely known worker, and was the author of valuable works and papers, relating not only to this special department, but to other branches of medicine, notably in the department of diseases of the nervous system. He was junior editor of the *Annales des Maladies de L'Oreille, du Larynx*, etc., and contributed to it some of its most valuable papers.

—— The sudden death of DR. BLOCK, of Dantzig, the well-known experimenter in lung resections, is announced.

—— *Uniâo Medica* announces the recent death of DR. CYPRIAMO BARBOZA BETTAMIO, Professor of Laryngology in the Rio de Janeiro Polyclinic.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 23 TO APRIL 30, 1883.

CLEARY, PETER J. A., *Major and Surgeon.*—So much of Par. 10, S. O. 273, November 23, 1882, from this office, as directs him (then Captain and Assistant Surgeon) to report in person to the Commanding General, Department of Dakota, is revoked, and, upon the expiration of his present sick leave of absence, to report in person for assignment to duty in the Department of the Missouri.—*S. O. 95, A. G. O., April* 25, 1883.

HOPKINS, WM. E., *First Lieutenant and Assistant Surgeon.*—Now on leave of absence in New York City, to be relieved from duty in the Department of the East, and assigned to duty in the Department of Arizona.—*Par. 7, S. O. 95, A. G. O., April* 25, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

MALARIAL HÆMATURIA.

THE ADDRESS IN MEDICINE

Delivered before the Medical Society of the State of Pennsylvania, at Norristown, May 9, 1883.

BY JAMES TYSON, M.D.,

PROFESSOR OF GENERAL PATHOLOGY AND MORBID ANATOMY IN THE UNIVERSITY OF PENNSYLVANIA; ONE OF THE PHYSICIANS TO THE PHILADELPHIA HOSPITAL, ETC.

PERHAPS the most important form of hæmaturia and hæmoglobinuria resulting from general causes is that due to malarial poisoning. I prefer the term malarial to intermittent or paroxysmal, not only because it more precisely indicates the cause of the condition, but also because the condition itself is by no means always intermittent, but sometimes continues without interruption until checked by appropriate treatment, and I have known it to continue uninterruptedly for a year, notwithstanding all treatment.

The first complete report of an undoubted instance of this affection appears to have been published by Dressler, in 1854,[1] although incomplete and uncertain cases were reported prior to this date—one as early as 1832,[2] by Elliotson. Dr. George Harley[3] early contributed to our accurate knowledge of the subject in 1865, and since then numerous papers and reports of cases have appeared in English and American journals, the southern part of the United States being a fertile scene of the affection, while it is by no means rare in our own State.

Two degrees of the disease are met with, a milder form in which other symptoms as well as the hæmaturia are less pronounced, and of which instances occur in the Middle States as well as the South and West of this country. Of this kind seem to be the cases studied by Harley and other English physicians. In addition to this, there is a second more malignant form, attended by great prostration, vomiting, and yellowness of the skin, along with copious discharges of bloody urine. Instances of the latter are numerous in the Southern States of this country, where they have recently been studied with considerable care; also in the East and West Indies, and in tropical countries generally. In neither degree of the disease is it necessary that the red corpuscles of the blood should be present. They may be represented by their coloring matters alone, when the condition is called a hæmoglobinuria or a hæmatinuria.

To ourselves, at this time, the milder, but sometimes quite intractable form, is more interesting. The victims who, in my experience of seven cases, have invariably been men, and I believe this is the experience of others also, are generally able to recall a history of exposure to malaria, and often of distinct attacks of malarial fever, intermittent and remittent. The hæmaturia appears suddenly, and when paroxysmal may occur daily, or on alternate days, or a couple of times a week, or even at longer intervals. When the attacks occur at longer intervals, say of ten days or two weeks, if the disease is left alone the interval is apt to gradually diminish, until the passage of bloody urine becomes daily. The urine in the morning may be perfectly clear, and at two o'clock is evidently bloody. It continues so through one or two acts of micturition, and then becomes clear again; or it may be bloody on rising and clear up by noon. Sometimes the bloody urine is preceded or accompanied by a sense of weariness and chilly feeling, or sometimes simply by cold hands and feet, or by cold knees, or by pallor and blueness of the face, or by accelerated pulse, or by no other symptoms whatever. There is sometimes a sense of fulness in the region of the kidney and sacrum.

Dr. Harley states that in one of the two cases which he reported, there was a slight jaundice, and in the second a "sallowness which appeared to be due to a disturbance of the hepatic functions," but in none of the cases which I have met was this symptom present. In the more malignant form occurring in the tropics, and Southern States of America, jaundice is a constant symptom.

While a majority of cases of malarial hæmaturia are intermittent, many are continuous, and of my seven cases only two were distinctly intermittent. One of these cases I published in a clinical lecture in the *Philadelphia Medical Times*, as far back as September 1, 1871.

Negroes are not exempt from this milder form of the disease, as they seem to be from the more malignant form of the South. While writing this paper, I was consulted by a negro, thirty-one years old, who had a true malarial hæmoglobinuria which yielded promptly to the treatment by quinine. But this was the only case of a negro out of seven.

Physical and chemical characters of the urine.—The urine is usually acid in reaction when passed, sometimes neutral, rarely alkaline, and ranges in specific gravity from 1010 to 1028. It is always albuminous, and always tinged by blood-coloring matters, the depth of color varying from the trifling degree known as "smoke-hued" to a dark-red or claret color. Sometimes it is even darker and is often compared to porter, though this degree of coloration is more characteristic of the malignant form. The urine deposits a dark, reddish-brown sediment, which is generally copious, but varies with the degree of coloration of the urine. This sediment is made up chiefly of red blood-disks or the granular debris resulting from their disintegration.

Casts of the uriniferous tubules are also often present. They are usually made up of aggregated red blood-disks or the granular matter referred to; but they may also be hyaline, or hyaline with a moderate amount of granular matter attached. Granular urates, also, at times contribute to the sediment, and also adhere to the casts.

That red blood-disks are at times exceedingly scarce and even totally absent at the very moment when the urine is passed is a well-recognized fact; while that the coloring matter present is still that of the blood, even though no corpuscles are present, is easy of

demonstration by the production of Teichmann's hæmin crystals[1] or by spectrum analysis.

In the matter of the presence or absence of blood-disks, it is to be remembered that these may be present at the moment the urine is passed, but disappear by subsequent solution if the urine happens to be alkaline or becomes so secondarily. It is an interesting fact, too, that the colorless blood-corpuscles are often present intact, even when the red disks are absent. While I have frequently examined urine sent me from the South, in which only the coloring matter of the blood and no corpuscles were present, but one of the cases coming under my own observations furnished urine of this character.

Pathology and Morbid Anatomy.—The pathology of malarial hæmaturia consists, as yet, chiefly of theoretical deductions. We can only conclude that the malarial poison acts upon the blood and bloodvessels, impairing the integrity of both. This goes so far occasionally as to produce an actual destruction of blood-disks, and always so alters the capillaries that they permit the transudation of blood elements ordinarily retained.

The morbid anatomy is scarcely more precisely defined. Ponfick[2] goes so far as to say that the exudation of hæmoglobulin is not possible without the concurrence of marked diffuse nephritis. Recently, Lebedeff[3] has sought to investigate the more minute alterations of the kidney in hæmoglobin exudation, but without very definite results. These, however, on the whole, seem to confirm Ponfick's view as to the presence of an inflammatory process.

Diagnosis.—The diagnosis of this condition is not usually difficult. We have first to determine whether the hemorrhagic discharge is from the kidney rather than the bladder or ureters. This is certain if tube-casts are present. But tube-casts are not always present even when the hemorrhage is from the kidneys. The absence of clots and of vesical irritation, and of pain in the course of the ureters, is characteristic of blood from the kidneys. Finally, all hæmoglobinurias are renal.

It being certain that the blood comes from the kidney, we have to distinguish it from that due to cancer, to calculous irritation, and to cachexias, as purpura and scurvy; or to grave forms of infectious disease, septicæmia, pyæmia, etc.; or, finally, to poisonous substances introduced into the blood, such as arsenic, iodine, arseniuretted hydrogen, carbonic acid and carbonic oxide gas, and even certain species of edible fungi.

In the first place, the diagnosis is greatly aided if it is found we have to do with a hæmoglobinuria rather than a hæmaturia. For although the former condition is produced by toxic and septic agencies of another kind, the attending symptoms, when it is thus produced, are so characteristic that it is not likely that error can be made.

To aid in distinguishing it from cancer, we have the history of malarial exposure, and often that of other forms of malarial disease; and, notwithstanding the seeming drain upon the system, none of the cases I have ever seen present the profound anæmia of cancer. The bloody discharge in cancer of the kidney is always a true hæmaturia—there are always blood-disks in the urine. There is often pain in the region of the kidney in cancer, but never in malarial hæmaturia.

In calculous disease there is almost always pain before or during the hæmaturic attack, and characteristic crystalline sediments often appear in the urine.

The disease, being comparatively rare in this latitude, is sometimes overlooked on this account. Of the seven cases which I have noted during fifteen years, five originated in Pennsylvania, one in New Jersey, and one in North Carolina.

Treatment.—The treatment is distinctly that of malarial disease, and I have seldom seen more brilliant and satisfactory results than have followed the use of *quinine* in a case accurately determined, although such results are not invariable, and I have known the disease to resist for a long time the most thorough and judicious use of anti-malarial remedies. Usually, however, I take hold of a case of this kind with considerable confidence. When there are distinct remissions, my practice has been to administer sixteen to twenty grains of sulphate of quinia in the usual manner of anticipation of the paroxysm in intermittent fever—from three to five grains every hour until the required amount is taken; the whole amount may be taken in two doses or even in one dose. Where there is no distinct remission I more usually direct three to five grains every three hours, until the hemorrhage ceases or decided cinchonism is produced.

The advantage well known to accrue in malarial disease from the combination of mercurials with quinine, applies to hemorrhagic malaria as well, although I usually reserve the mercurial until I have ascertained whether the simple quinine treatment answers the purpose. If the usual method fails, I give eight or ten grains of calomel in the evening followed by a saline in the morning, before reinstituting the quinine treatment. In the case of the colored man alluded to, who had malarial hæmoglobinuria, thirty-six grains of quinine failed to break the attack; but the same quantity given after ten grains of calomel had acted, succeeded.

Where these means failed, I have not found the other methods of treatment commonly resorted to in obstinate malarial disease to be any more efficient. I allude to the treatment by *arsenic*, or by *iron* and arsenic. Indeed, in the only two cases in which, after failure with the quinine treatment, iron and arsenic were used at my suggestion, they failed absolutely. In the one case under the care of my friend, Dr. James L. Tyson, this treatment was carried out most faithfully. After four weeks' treatment with quinine without effect, Fowler's solution was given at first in five-drop doses three times daily, subsequently increased to ten, and fifteen, along with twenty and thirty-drop doses of tincture of the chloride of iron, until œdema of the eyelids occurred, when the arsenic was discontinued, but the iron continued. In two or three days the arsenic was recommenced in three and four-drop doses for three or four weeks longer without effect. Fluid extract of ergot in twenty-drop doses was then substituted for the iron, alternating with the arsenic for two weeks longer, when some slight favorable change was apparent, but it was temporary. Repeatedly throughout the treatment the patient complained of weariness and backache, cold feet and knees, headache and acceleration of pulse, and a feeling of "utter wretchedness;" and then again he would feel quite comfortable for a day or two, but with little or no change in the urine, except occasionally in the morning, when it would sometimes be quite light-hued, but after break-

[1] Place a drop of the sediment upon a glass slide and allow it to dry. Mix thoroughly with a few particles of common salt and cover with a thin glass cover, under which allow two or three drops of glacial acetic acid to pass. Carefully warm the slide for a few seconds over a spirit-lamp, and when most of the acetic acid is evaporated, examine by the microscope. Hæmin crystals will be seen to crystallize out as the mixture cools.

[3] Lebedeff, Zur Kenntniss der feineren Veränderungen der Nieren bei der Hämoglobinausscheidung. Virchow's Archiv, Bd. 91, S. 267, Feb. 1883.

fast would again assume its bloody character. A sojourn at the sea-side for two weeks was without effect.

It will appear from the above that *ergot*, which has been found useful in some forms of hæmaturia, is of little service here, as is attested by two other cases, in which I tried it faithfully. At the same time, it is a remedy which should be tried in case of failure with others.

The usual *astringents*, mineral and vegetable, of known efficacy in the treatment of hemorrhagic conditions, should be used alone, or in conjunction with the specific anti-malarial treatment, after the latter has been found of itself insufficient. To this class of remedies belong the mineral acids, persulphate of iron, acetate of lead, alum, gallic acid, catechu, kino, etc.

Rest is certainly an important adjuvant in the treatment of this form of malarial disease. I have known a recurrence to take place after a long drive in a carriage.

It is claimed for many *natural* mineral *waters* that hemorrhage from the kidneys is one of the affections cured by their use. *Chalybeate* and *alum* springs might be expected to be of advantage by the local action of these astringents in their transit through the kidneys, but my personal knowledge is limited to a single case. The results in this seemed, however, of such a decided character, that I report them, without desiring to attach to a single case an importance greater than it deserves. The patient was a lawyer, who consulted me in June, 1881, at the suggestion of Dr. W. W. Covington, of North Carolina. He had frequently had "chills," and a congestive chill in 1873. Three months before I saw him, he began to pass bloody urine. He had no other symptoms, except a soreness and weakness in the neighborhood of the sacrum, extending into the outer part of the left thigh. The urine passed for me at the time of his visit was dark reddish-brown in color, acid in reaction, had a specific gravity of 1028, and deposited a sediment of almost tarry consistence, which was made up almost entirely of blood-corpuscles, and was, of course, highly albuminous. There were no tube-casts. He had been a dyspeptic since seventeen years of age, and medicines disagreed with him; but he was treated faithfully with quinine, iron, arsenic, ergot, benzoate of lime, all without the slightest effect. At the end of about a year from the time he consulted me, he heard of the Jackson spring, located in Moore County, North Carolina, fifteen miles distant from Manly Station, on the Raleigh and Augusta Railroad. He went there, and remained one week. He states that, for the first two or three days, the water acted decidedly on his kidneys, and he voided a number of clots of blood. *On the third day all traces of blood disappeared*, and it recurred but once since, on a very cold day, in November last, but again disappeared after a day or two in the house. This statement is so direct, and my patient is so intelligent and reliable, that I could not but be impressed by it, and I am quite anxious to repeat the remedy on another case. Unfortunately, no precise analysis of this water seems to have been made; but, from what my friend writes, it evidently contains iron and sulphur, and magnesia is also said to be present. It is promptly diuretic.

The following are some of the chalybeate and alum springs, the waters of which one would expect to be of service in hæmaturia, and some of which have a reputation for efficacy therein: Orchard Acid Springs, New York; Rockbridge Alum Springs, Pulaski Alum Springs, Bath Alum Springs, Stribling Springs, and Bedford Alum Springs, all in Virginia. In all of these waters, iron and alum are both present, accompanied, in many instances, by free sulphuric acid, by which their efficiency is increased. In one of my cases, the hemorrhage disappeared temporarily under the use of the water from the Bedford Springs, Penna., but again returned. These waters contain a little iron, but no alum. Subsequently, the same patient was promptly relieved by quinine, which had not been previously tried.

Malignant Malarial Hæmaturia.

The second more serious form of this disease, as it occurs in the tropics and the southern part of the United States, is characterized by such increased intensity of all the symptoms that it may be well called "malignant." Singularly, however, the disease has seemed to be much more prevalent during the last fifteen years. My attention was first called to it in September, 1868, when I received specimens of urine and the history of some cases from Dr. R. D. Webb, of Livingston, Ala., who wrote also that it was not known in that part of his State, at least prior to 1863 or 1864.

In this, as in the milder form, there is a distinct but more invariable history of malarial exposure, and the attack often begins as an ordinary case of chills and fever, there being often one or two paroxysms before the hæmaturia appears. At other times, the hemorrhage ushers in the disease suddenly. The urine is often black and almost tarry in consistence, and passed in unusually large quantities—it is said as much as a pint every fifteen or twenty minutes until a couple of quarts have been passed, or one or two gallons in the course of twelve hours. But after twenty-four hours, the quantity diminishes. Epistaxis sometimes occurs, but is not often profuse. Distressing nausea and vomiting of bilious and even black matter, like that of "black vomit," also occur. Intense jaundice rapidly supervenes, said to come on sometimes in the course of an hour, often in from two to six hours. The tongue is brown and dry. The bowels are at times constipated, and at others loose. Although the patient may be feverish at first, with a temperature of 104° to 106°, and the skin dry, the pulse rapidly becomes small and feeble, until it is scarcely perceptible. Drowsiness and coma sometimes intervene, and at others the mind is clear until the moment of death, which frequently supervenes within twenty-four or sixty hours; or the symptoms may subside, to be repeated again the next day, if not prevented by treatment. If recovery takes place, which it sometimes does, and lately more frequently, convalescence is slow and tedious, the patient remaining for weeks in an enfeebled and anæmic state.

In this form of the disease especially, it often happens that the coloring matter only and the debris of blood disks are found in the urine, very few and often no entire ones being discernible—in other words, we have a true hæmoglobinuria or hæmatinuria. The urine is, of course, albuminous. A specimen recently received from North Carolina, and analyzed by Prof. Wormley, contained no corpuscles, but revealed the spectroscopic band characteristic of hæmoglobin. It contained two and a half per cent. of urea. The specific gravity of the urine ranges between 1010 and 1020, being lower when it is copious.

As to the jaundice, it is evidently a hæmatogenetic, and not a hepatogenetic form with which we have to deal. It is due, not to the retention of bile, but to the disintegration of blood corpuscles, and the solution of their coloring matter which diffuses through the tissues and stains them yellow or yellowish-green. This form, too, apparently is more frequent in males, and negroes appear to be exempt. This is not the case with the milder form, for it will be remembered that one of my patients was a negro.

Autopsies reveal the same intense yellow coloration

of internal organs—lungs, liver, spleen, stomach, kidneys—anæmia rather than congestion, while the blood is dark-hued and is indisposed to coagulate. The spleen is often enlarged.

The *treatment* for the breaking of the paroxysm is preëminently quinine, or quinine with mercurials; and although this does not always succeed, there seems to be no other remedy. The quinine may be given hypodermically. The nausea has been controlled by morphia and lime water, by carbolic acid, and by creasote. In addition, restorative measures are necessary, including the free use of stimulants. Turpentine has been used in large doses (f3j), but this does not seem a very rational treatment.

ORIGINAL ARTICLES.

THE USE OF THE MODERN DWELLING-HOUSE AS A MATERNITY.

By F. A. BURRALL, M.D.,

PHYSICIAN TO THE PRESBYTERIAN HOSPITAL; MEMBER OF THE MEDICAL COMMITTEE, NEW YORK INFANT ASYLUM, ETC.

The principal aims in the establishment of a maternity, as usually understood, are the purchase of a suitable piece of property upon which buildings adapted for the special object may be placed, and then the erection of the buildings. These are the objective points most prominent in such an effort, and require so much time for their accomplishment that a beneficent work may often be delayed for months or years.

The end in view is the carrying on of an obstetric service with the least amount of sickness or death, and the question arises, may not such an end be attained without the usual delays? This matter has a special interest in the growing medical history of this country, since infant or foundling asylums, with the obstetric service incident thereto, are likely to be established in the larger cities of the Union, and the fewer obstacles which stand in the way, the more easily are they inaugurated, and the more promptly may such a work be begun.

Is it necessary to purchase land and erect buildings for the purpose? May not the modern dwelling-house serve the want? and if so, for how long a time can such a house be used satisfactorily?

Such an experiment has been tried in New York, and it seems desirable to place the results on record for guidance under other circumstances of a similar character.

The Managers of the New York Infant Asylum opened the house, No. 24 Clinton Place, New York, in November, 1871, as a house of reception for unmarried pregnant women, as well as abandoned children of two years old and under, and it was used for "lying-in service." The house was about 25 by 50, of brick, and had three stories, with attic and basement. It was in a central part of the city, and had the usual appointments of gas and water. It was heated by furnace and grates, and in one of the rooms by a stove. In short, it was a dwelling-house which had become somewhat old-fashioned as compared with the pretentious and complete structures of recent years. During the first two years I attended to the confinements, then resigned, and Dr. H. D. Nicoll took charge of the cases until October, 1875, when, as the service became more arduous, Dr. E. L. Partridge was appointed assistant physician, and remained in attendance until the closure of the building for lying-in purposes, October 13, 1876. From the commencement antiseptics were used, both in the washing of the wards and as local applications to patients during lying-in. Isolation of cases in the least suspicious was carried out as far as practicable. Sponges were discarded, and the idea of preventing puerperal contagion was kept constantly in view. One of the rules of the house, adopted at a meeting of the Medical Committee, was, "that the attending obstetrician must always wash his hands thoroughly, annoint them, and surround his wrist and forearm with a clean towel before making the usual examinations." The institution labored under the disadvantage of keeping lying-in women and children permanently under the same roof. At first this was a necessity, but other buildings were afterwards secured, and the policy was then maintained of reserving 24 Clinton Place for the obstetric service, and transferring the children, and mothers with very young children, to these other buildings.

From the first birth, which occurred December 14, 1871, until January 1, 1873, there were twenty-nine deliveries. Among these cases were two in which the forceps was used. No deaths and no zymotic diseases occurred. During the year ending January 1, 1874, there were fifty-five births, with no death of mothers. There was one case of metritis. From January 1, 1874, to January 1, 1875, there were seventy-five births with one death of a mother from uræmia with fatty degeneration of kidneys and metro-peritonitis. No zymotic disease prevailed.

During 1875, the house adjoining No. 24, which was on the whole similar in its construction, was rented to accommodate the increasing number of patients. Cases of emergency were also received from the Commission of Public Charities, which apparently rendered the asylum more likely to become infected, as many of this class of cases came from the filthier quarters of the city. Two doors, cut through the intervening wall of the buildings, one on the third and one on the parlor floor, afforded intercommunication.

In January, a case of erysipelas appeared in No. 24 Clinton Place, two weeks later a case of scarlet fever made its appearance, and one week afterwards three women developed symptoms of mild septic poisoning. Another case of erysipelas also made its appearance. These indications of an epidemic were promptly met by changing the lying-in ward temporarily and practising fumigation.

During this year there were one hundred and sixty-one deliveries, of which thirty-five were ambulance cases. One adult died from puerperal convulsions, the patient having previously suffered from epilepsy. There were two twin births, twelve deliveries with the forceps, and one craniotomy.

No. 26 Clinton Place was given up May 1, 1876, and no more ambulance cases were received. Up to October 13, 1876, when the last delivery occurred in No. 24 Clinton Place, there were eighty-four cases of confinement during this portion of the year

1876, with one death from puerperal fever and one from uræmic convulsions. A patient was transferred to the branch of the asylum in Sixty-first Street, and had severe puerperal fever, but recovered. There were also two cases of puerperal fever at No. 24 Clinton Place, which recovered.

Scarlet fever occurred once in the Institution before it was given up for obstetric uses, a child being the victim, but no second case followed, nor did there seem to be any modification of the lying-in condition in consequence. Every precaution was taken to insure this result.

A summary of the obstetric work done in 24 and 26 Clinton Place, shows that from Dec. 14, 1871, to Oct. 13, 1876—a period of about four years and ten months—there were 399 deliveries, with 5 deaths, only one of which was from puerperal fever. The others were, one from phthisis; one from uræmia, with fatty degeneration of the kidneys and metro-peritonitis; one from convulsions, in an epileptic patient; and one from puerperal convulsions.

A majority of the inmates of the Institution were primiparæ, and many had taken dangerous drugs before entrance, for the purpose of producing abortion and avoiding social disgrace. Chloroform was used when anæsthesia was necessary for obstetrical operations, with no unpleasant consequences.

The mortality from zymotic disease was, consequently, one in 399 cases, and 5 from all diseases.

The following table gives statistics relating to the lying-in hospitals of New York.

	Women Confined.	Deaths.	Per Cent.
Lying-in Asylum, 1856–76,[1] (Marion St.)	1923	21	1.1
N. Y. Infant Asylum, 1872–1876, . .	399	5[2]	1.2
Infirmary for Women and Children, 14 years, ...	995	12	1.2
1870–1876, ...	623	8	1.3
Nursery and Child's Hospital,			
(*a*) City, 1867–1876, ...	1479	60	4.1
(*b*) Country, 1872, and 1874–1877, .	365	11	3.0
Charity Hospital, 1874–1876, . . .	1381	36	2.6
Emigrant Hospital, 1868–1876, . .	3766	99	2.9

It has been estimated that one death occurs in 120 deliveries, but this is a crude method of calculation, something as if one should collect the results of ovariotomy and formulate a proposition that one death occurred in so many ovariotomies, without noticing the fact that this mortality may be made to vary by the neglect or observance of certain precautions. As compared with the results of other lying-in institutions, the record of Nos. 24 and 26 Clinton Place may be regarded as very satisfactory. It was felt, however, that the buildings were no longer tenable for lying in purposes, but the experiment proved that, at least in this case, the modern dwelling-house had, for a time, been available for the purposes of a maternity.

As compared with the mortality in the present lying-in department at the buildings on the corner of Sixty-first Street and Tenth Avenue, the modern dwelling has still a favorable record. This branch of the institution is situated on high ground, with dry soil and good facilities for drainage, and the site would be supposed to offer decided sanitary advantages. The same policy of cleanliness, and the use of antiseptics and rotation of lying-in wards have been advocated, and when the service is transferred from one ward to the other, the ward which is left is thoroughly fumigated. A maternity cottage, separate from the other buildings, has been erected here, but it may be remarked, *en passant*, that since the opening of this cottage it has, from some unexplained cause, developed the presence of puerperal disturbants more than the wards in the pavilion or main building near.

Of the 577 women delivered in the buildings at Sixty-first Street from August, 1877, to January, 1882, 5 have died from puerperal fever, 1 from puerperal convulsions, 1 from uræmic convulsions, and 1 from puerperal septicæmia. From other than puerperal diseases there have been 8 deaths, making a total of 16 from all causes. This is an increase in the rate of mortality when compared with that of 24 and 26 Clinton Place, and yet the list is here also comparatively free from zymotic diseases.

The obstetric teachings drawn from the records of the New York Infant Asylum are in favor of cleanliness and the use of antiseptics, a lying-in service of moderate numbers, frequent changing of wards, and isolation of suspected cases. Occasionally a number of those recently confined would develop unusually high temperatures, and this circumstance was always regarded with anxiety and watchfulness, as indicative of the presence of some baleful influence. It has sometimes preceded puerperal disease. This rising of the mercury was the earliest symptom of coming trouble, and, in fact, the thermometer in the lying-in ward is an obstetric barometer which announces to the physician the approach of a coming storm; the thermometer, by the rising, as the barometer by the falling column.

A disadvantage of the dwelling-house for lying-in uses arises from the fact that patients who may be in the incubative period of a contagious disease are admitted directly into the wards. This could be obviated to some degree by having two houses adjacent, and using the upper portion of one for newly admitted patients. But it may also be said that this disadvantage is common to many hospitals. An advantage is evident when it is borne in mind that, like a tent, the dwelling-house may be promptly abandoned, if it becomes infected. The sentiment of modern sanitary construction is in favor of temporary shelters. Vast piles of granite may make charity conspicuous and proud, but these great buildings foster zymosis, as carcasses breed maggots.

The question arises, whether a building which has been used as a maternity remains infected, so as to render it objectionable for future tenancy, especially of those likely to become mothers. To learn this, it would be necessary that a confinement should have taken place in a building which had been used for lying-in purposes, and the result be noted. Such evidence I have been unable to secure, but have learned that there was a record of only one

[1] On Lying-in Institutions, by Henry J. Garrigues, A.M., M.D. New York, 1878.

[2] Only one of these was from puerperal fever.

death in the fifteenth ward—where the buildings of which I have written were situated—from puerperal fever during 1877, and this was many blocks away. Dr. John T. Nagle, of the Metropolitan Board of Health, kindly informed me, in a note dated Oct. 28, 1882, that, "I have found in searching the records from 1880 and 1881 to date, that there was one death —a child under five years of age—from scarlatina at 26 Clinton Place, in 1881; there were no deaths in 24 Clinton Place, 1880, to date." Hence the evidence, as far as it goes, is rather against the existence of any permanent poisoning of such buildings. Besides, if necessary, fumigation could be practised when the buildings were abandoned for hospital uses.

TREATMENT OF ULCERS BY MECHANICAL CONTRACTION OF THEIR AREA.

BY WILLIAM PENNY, M.D.,
OF GALVESTON, TEXAS.

J. H., came to me from the country, suffering from a severe scalp wound over four inches in length, situated on a line with the junction of the left parietal and frontal bones. The wound was gaping widely, secreting pus profusely, and extremely irritable. I shaved the scalp and applied strips of adhesive plaster, but finding that I could not get sufficient traction in this way, I applied strips of plaster nearly as wide as the wound was long, with a series of holes punched on the side next the wound, through these holes I passed a cord, lacing the two strips together like a shoe. The patient came back after a few hours to have the lacing tightened, saying that it made the wound more comfortable. Seeing that the retraction of the edges of the wound was due to the contraction of the cut fibres of the occipito-frontalis, as well as of the muscular and elastic fibres of the derma, I substituted a rubber cord for the non-elastic one in use. The next day the patient returned, highly pleased at having spent such a comfortable night. I then removed my strips with the lacing, substituting strips of adhesive plaster with hooks on the end which was placed next the wound, using small rubber bands for connecting the opposing strips. This completed the dressing, and is the form which I now use.

The continuous traction and moderate compression exerted by this dressing relieves the ulcer of its hyperæmic condition; its thickened edges soften down; the excavation fills rapidly, and the remaining cicatrix is small and remarkably flexible.

I have used this strapping in a large number of cases, including varicose ulcers of the leg; syphilitic ulcers upon the scalp, leg, body, etc., some of large size, with the most satisfactory results in all the cases treated. Recently I used this dressing in two ulcers: one on the outer aspect of the arm just above the elbow; the other over the tibia below the patella. We all know the difficulty of healing an ulcer near a joint owing to the great motility of the parts. The strapping gave physiological rest to the structures, and cicatrization proceeded rapidly.

A short time ago I applied the strapping in a case where the breast was amputated for cancer. In this case there was a very large gap to be filled. Under the steady traction of the rubber bands the flaps approached each other, and in twenty-four hours the wound was closed.

One of the chief advantages of this strapping is the great saving of time in dressing wounds. The rubber connecting bands can be removed in a moment's time, the wound or ulcer dressed, and in less time than it would require to remove the ordinary adhesive strips.

MEDICAL PROGRESS.

TREATMENT OF FISTULA IN ANO.—During a discussion at the Société de Chirurgie in October last, on a paper communicated by Dr. Queirel, of Marseilles, M. VERNEUIL argued that the elastic ligature—though probably suitable in cases of small anal fistula, without diverticula or undermining—had no advantages over the thermo-cautery, by which the division could be rapidly effected. The bistoury, he holds, ought to be abandoned in the treatment of anal fistula, as it exposes the patient to the risks of hemorrhage and erysipelas. The thermo-cautery never causes primary, and is rarely followed by secondary hemorrhage. In the use of the ligature, the patient is not free from the risk of secondary hemorrhage. Relapse is to be feared in one or other of two different conditions. Most frequently it occurs as a consequence of an incomplete operation. In phthisical subjects relapse takes place, no matter what method has been employed. With the ligature the operation is likely to be incomplete; for, in order to remove the fistula, it is necessary to follow all its prolongations. If each of these be treated by a ligature, the operation becomes more complicated than an application of the thermo-cautery. One of the disadvantages of the ligature is the pain to which it gives rise. A young woman to whom Verneuil applied a ligature for the treatment of fistula, after three nights of insomnia through intense pain, died ten days later from pneumonia. M. Verneuil thinks that patients as a rule are not able to follow their occupations during the treatment by ligature; besides, he would not under any circumstances permit any patient to move about for some days during such treatment. In a diabetic patient, M. Verneuil would prefer the use of the actual cautery to that of the bistoury or of the ligature. The ligature, it is held, is impracticable in many cases in which the fistula is long and the walls are thick, and when there are many prolongations. It will, of course, be preferred by timid subjects, but in employing the thermo-cautery the surgeon can always use chloroform.—*London Med. Record*, April 15, 1883.

SUBPHRENIC PNEUMOTHORAX, OR FALSE PNEUMOTHORAX.—LEYDEN records (*Zeits. f. klin. Med.*, t. i. p. 320) three cases of false pneumothorax. In the first case the super-hepatic collection was opened by Langenbeck, but the patient died. The disease was recognized in the other two cases, but there was no operation, and death occurred. The principal elements of diagnosis are: 1. The affection is preceded by symptoms of peritonitis (by perforation), or by the appearance of pus in the stools. 2. Formation of an exudation of an inflammatory nature, without cough or expectoration. 3. Appearance of the classical signs of pneumothorax, while examination of the chest shows that the lungs are sound. 4. The limits of the dulness vary very rapidly with changes in the attitude of the body; always at the base of the thorax. 5. The signs

of increase of intra-pleural pressure (bulging of the thorax as a whole, and of the intercostal spaces, and displacement of the heart) are absent, or but slightly marked, and at the same time the liver is pressed down in the abdomen. 6. Later, perforation into the bronchia confirms the diagnosis. 7. Finally, manometric measurement of the thorax, indicates an augmentation of pressure on inspiration and diminution on expiration, which is contrary to what is seen in true pneumothorax.

Menthol in Facial Neuralgia.—Dr. C. D. Cammann recommends a mixture of menthol, ʒj, and alcohol, ℥ss, as an efficient remedy in many cases of facial neuralgia. This mixture is to be painted over the part several times daily with a camel's-hair brush. It has also been of service in pleurodynia and lumbago.—*Medical Record*, April 28, 1883.

Cyanuret of Mercury in Papillar Atrophy.—M. Galezowski has treated several cases of papillar atrophy of syphilitic nature, by injecting subcutaneously in the temporal region a gramme of distilled water containing one-thirteenth of a grain of cyanuret of mercury. The injections are repeated daily; but it is dangerous to go above one-sixth of a grain, as a troublesome diarrhæa may supervene. The double cyanurets of gold and potash, of silver and potash, sometimes act very favorably in papillar atrophy of ataxis.—*Le Progrès Méd.*, April 14, 1883.

Secondary Uterine Hemorrhage.—Dr. John Phillips reports a case of secondary uterine hemorrhage, occurring fourteen days post partum. At the time of delivery the placenta was removed entirely with the membranes, and the uterus contracted firmly. Patient had had two malarial chills just before confinement, and one on the day of labor, which were broken up by sulphate of quinine; believing that a malarial condition was the cause of the recurrence, full doses of quinine, with fl. ext. ergot to control the hemorrhage, were administered, with the desired effect.—*Clinical Brief and Sanitary News*, April 8, 1883.

[Dr. Paul F. Mundé has reported a similar, but more serious case, in a paper read before the N. Y. Academy of Medicine, January 18, 1883. See Medical News, January 27, 1883.]

Antiseptics in Midwifery.—Dr. John Williams read an interesting communication before the Harveian Society on "Antiseptics in Midwifery in Lying-in Hospitals and Private Practice." The means, as he stated, taken at the Hospital for Women and Children, for avoiding septic infection, were perfect cleanliness in the patients themselves, strict attention to the state of the wards, which were cleaned daily, and were periodically cleared of patients and disinfected with sulphur; during parturition an antiseptic inunction of the head of the child and of the vagina during each pain, and after delivery vaginal douches with warm water.—*British Medical Journal*, April 21, 1883.

Melanuria.—Dr. Zeller found this hitherto seldom observed occurrence in a man of 43 years, affected with melanotic sarcoma of the skin, who died six weeks after his entrance into the clinic, apparently of cerebral complication. The very dark-brown clear urine gave a small increase of sulphuric ether above normal; no increase of phenol or indoxyl, and a large amount of hydrobilirubin. Between this latter and the dark coloring matter was a stratum in which was found much urobilin and little melanin; in the darker stratum, in which there was little or no urobilin and much melanin, with bromine water he obtained a rich, yellow, amorphous precipitate, which became dark-black on standing. This bromine-water reaction is much more easily shown than the reaction with nitrate or chromate of potash hitherto employed. Brommelanin, when dried, is a glistening black mass, which, on triturating, leaves a brown powder. A solution of urobilin gives with bromine water a yellow precipitate, which never becomes black on standing. Fever urine with much urobilin, like normal urine, never gives a black precipitate with bromine water. Zeller believes that the coloring matter of the urine must arise from two sources, either from the hydrobilirubin contained in the bile, or the blood coloring matter. He thinks, from his experiments, that melanin belongs to the first group, but further confirmatory experiments should be made.—*Berliner klin. Wochensch.*, April 16, 1883.

On the Operative Treatment of Ozæna.—In 1881 (*Centralbl. für Chirurgie*, 1882, No. 5) Volkmann operated on two cases of simple fetid ozæna, in young girls, by removal of the lower, and the greater part of the middle, turbinated bones. Disinfecting and astringent solutions, which had previously been used for months and years without effect, now caused the penetrating smell to disappear. In both patients the nose was naturally very narrow, the lower meatus being only permeable to very narrow instruments. The nose was at the same time asymmetrical, the vomer being bent and the turbinals nearly occluding the nostrils. In one case there was much velvety swelling and general injection of the nasal mucous membrane with abundant secretion; in the second there was cicatricial contraction with the formation of hard crusts. The method of operating is as follows: A strong concave gouge, of as large a size as possible, is introduced into the nostril, and, with due regard to the direction of the middle meatus, is pushed forcibly onwards by two or three thrusts of the hand, the concavity of the gouge being directed first inwards and then downwards. Any loose pieces of turbinated bone may afterwards be removed with forceps, and plugging be resorted to if there be much hemorrhage.—*London Med. Record*, April 15, 1883.

Removal of Pin from the Larynx, by Internal Operation, after Impaction for Thirteen Months.—Dr. Felix Sémon read, before the Clinical Society of London, the notes of the following very interesting case: Boy, æt. 13, on November 25, 1881, while holding a pin in his teeth, lost control of it, and in attempting to remove it from his mouth, it was pushed further down and became fixed in the left side of his throat. No immediate serious symptoms followed, but during the next twelve months he had several paroxysms of pain in the left side of his throat, difficulty in swallowing solids, and spasmodic cough. These paroxysms became more frequent, and the patient entered the St. Thomas Hospital Oct. 30, 1882.

Dr. Sémon made a laryngoscopic examination, and found that the pin was not in the œsophagus, but in the larynx, and that its point projected into the gullet. The point projected about one-eighth inch out of the arytenoid end of the left ary-epiglottic ligament, in close proximity to the base of the left arytenoid cartilage. The parts in its immediate neighborhood—left border of the epiglottis, left ary-epiglottic fold, and left arytenoid cartilage—were considerably tumefied, and the left arytenoid cartilage remained immobile during phonation and respiration. Voice normal; no dyspnœa.

After removal of the hypertrophied tonsils, and a short preliminary practice with the laryngeal probe, Dr. Sémon, on Dec. 26, 1882, succeeded in seizing the pin, under the guidance of the laryngeal mirror, with a

pair of lateral serrated forceps and extracting it. The length of the pin was one inch and a quarter. Four days afterward, it was ascertained by laryngoscopic examination that there was immobility of the left arytenoid cartilage, it, with the left vocal cord, remaining immobile during inspiration and phonation. Though the glottis only opened to half its normal breadth, there was no dyspnœa. During phonation the right vocal cord completely joined the immovable left, and the voice was normal. Dr. Sémon remarked that cases of successful extraction through the mouth of foreign bodies after so long an impaction, and after the production of such considerable lasting changes in the larynx as were observed in this case, had been but rarely reported.—*Med. Times and Gaz.*, April 21, 1883.

RESULTS OF HERNIOTOMY UNDER ANTISEPTICS.—HERR BENNO SCHMIDT, in a paper read before the Twelfth Congress of the German Surgical Association, shows that the mortality in herniotomy has markedly decreased since the operation has been conducted antiseptically. Of three hundred and two operations for incarcerated hernia between 1875 and 1881, the mortality was only 36.6 per cent., a reduction of 9 2 per cent, the mortality before the introduction of Listerism being 45.8 per cent. It was probable, however, that the mortality would not be further reduced, since the operations were almost all conducted antiseptically. Dr. Gussenbauer thought that it was not so much the manner in which the operation was conducted, as the gravity of the case, which determined the mortality.—*Berliner klinische Wochensch.*, April 16, 1883.

TREATMENT OF PLACENTA PRÆVIA.—MR. ASHTON proposes to substitute the use of the long forceps for turning when operative interference is necessary, and when the head presents, and when the placenta prævia is partial—where it completely covers the os at the beginning of labor, but where, after some progress, it only partially covers it—or when there is exhaustion from previous ill-health or from loss of blood. Version is indicated when the cervical attachment of the placenta is too extensive to allow application of the forceps; when there is malpresentation of the child; and where there is contraction of the pelvis or any condition usually indicating the operation. Craniotomy may be indicated when exhaustion is great, or in the usual indications for it.—*London Medical Record*, April 15, 1883.

IODIDE OF POTASSIUM IN ENTERIC FEVER.—DR. JÉLENSKI reports a series of twenty cases in which iodide of potassium was used as the chief remedy, and with very satisfactory results. From his observations it may be said that with the use of iodide of potassium there is a regular duration of fourteen to sixteen days. This, says Jélinski, cannot be claimed for any other remedy. The slow, though sure, lowering of the temperature is not temporary as with other remedies. There is a cessation, under the use of iodide of potassium, of the abdominal pain and diarrhœa. The period of convalescence seems to be shortened by the use of this remedy, and the disagreeable after-effects noticed with other antipyretics, do not occur. From these effects Jélinski is inclined to regard it as a specific in typhoid.—*Berliner. klin. Wochensch.*, Mar. 19, 1883.

ON THE LOCAL TREATMENT OF PULMONARY CAVITIES.—DR. SOKOLOWSKI (*Deutsche Med. Wochensch.*, 1882, and *Centralbl. für die Med. Wiss.*, Dec. 23, 1882), in a patient with a cavity below the right clavicle, injected a one per cent. solution of carbolic acid in the second intercostal space, about two inches from the sternum. The injection was immediately followed by severe dyspnœa and blueness of the face, which lasted for about two minutes, and was for a short time followed by a dry cough; the temperature rose, and did not fall to its normal degree until the next day. Subsequently, three similar injections were made without any other signs of reaction beyond elevation of temperature. Two injections of a five per cent. solution of tincture of iodine were afterwards employed, with scarcely perceptible reaction, and unattended with dyspnœa. Meanwhile the general condition of the patient became worse. Dr. Sokolowski has treated several other cases of phthisis by these local injections, with no good results.—*London Med. Record*, April 15, 1883.

INHALATION OF IODOFORM IN TUBERCULOSIS.—DAVEZAC, of Bordeaux, has used iodoform by inhalation, in twenty-six cases of tuberculosis. He uses a flask with a large opening, capable of containing about f℥viij. In the mouth of the flask is a cork stopper pierced with two holes for a glass tube tapering at its lower end, and a second tube bent at a right or obtuse angle, terminating at the base of the neck of the flask, and having attached to its outer extremity a piece of caoutchouc tubing about four inches long, to the other end of which a glass tube is firmly attached. Two small corks close the upper extremity of the tubes when the inhaler is not in use.

The medicament occupies the lower third of the flask. The formula used by Davezac is Pulv. iodoform, grs. xx; Essence of turpentine, f℥jss; Essence of bergamot, and Thymic acid, āā grs. xlv; Oil of almonds, f℥v or vj. These inhalations appear to give satisfactory results in diminishing the cough, and modifying the expectoration of cases of phthisis.—*Le Progrès Méd.*, April 21, 1883.

INJECTIONS OF CORROSIVE SUBLIMATE IN GONORRHŒA.—DR. LEISTIKOFF (*Deutsche Med. Zeitung*, Sept. 7, 1882) confirms the statements of Neisser as to the presence of a special bacterium in gonorrhœal discharges. In the first stage, when the discharge is thick and abundant, few of the bacteria can be seen. They are found in great numbers in the thin secretion of the later stages, in some cases lasting a year. Leistikoff employs an injection of corrosive sublimate, which Koch has found most fatal to bacteria; a solution never stronger than 1 part to 20,000; in private practice, a still weaker solution of 1 part to 30,000. The injections are used three times a day, and continued three or four days after discharge has ceased. The bacteria disappear, or are greatly diminished in number, after one day's use of the injections, but return if the latter be discontinued too soon. Treatment by injections should not be begun until the acute inflammation has subsided.—*London Med. Record*, April 15, 1883.

NITRITE OF AMYL AND NITRO-GLYCERINE IN URÆMIC ASTHMA.—MR. SHEEN reports a case in which nitrite of amyl was inhaled with most satisfactory result in the asthma of chronic Bright's disease. When seen, the patient was sitting in bed, gasping for breath; pulse feeble; tongue pale and sodden; moist râles over the whole chest; urine containing one-fourth albumen; could only speak a few words before he had to stop for breath. He inhaled ♏iij of nitrite of amyl, and within a few minutes his breath was easier, and he was able to recline in his bed. He was then put on nitro-glycerine, ♏$_{I\frac{1}{100}}$ t. i. d. He continued in the improved condition until twelve days afterwards, when he had another attack, and died in thirty-six hours, the urine being loaded with albumen.—*Brit. Med. Journ.*, April 28, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MAY 12, 1883.

SEASHORE SANITATION.

THE pursuit of recreation, rest, and health at some pleasant resort, has of late years become so generally indulged in during the summer season by the denizens of cities and large towns; and the exodus of the people from populous places during the heated term is assuming such large proportions, as to cause an annually increasing demand for temporary accommodations in the country, among the mountains, and at the seaside. To "get out of town," even though for the briefest period, seems to be an object inseparably connected with the plan of summer-life. The summer excursion of greater or less proportions is now deemed indispensable by all classes of people. In localities not distant from the coast, the seashore seems to be the place of popular resort, partly from the novelty, enjoyment, and healthfulness afforded, and partly from its easy accessibility and economy.

Under the impulse of the annually increasing tide of pleasure-seekers and valetudinarians, the old-established resorts are extending their bounds, and new ones are springing up as if by magic. A very serious question suggests itself just here, in regard to the sanitary status of these places, which is especially pertinent at this time, as reports have reached us that arouse a suspicion that all is not right in this important particular in many of the neighboring seashore resorts. Are these places, as they should be, under strict sanitary regulation and surveillance, as is implied in the very name of "health resort"? We regret to say that they are not; and this neglect is annually becoming more and more apparent, through the repeated reports of cases of preventable disease caused during a sojourn in these localities.

We are glad to learn that the Board of Health of New Jersey has directed a careful sanitary inspection to be made of the numerous summer resorts along the coast of that State. This action has not been undertaken a whit too soon to prevent an outbreak of zymotic disease in the season when the crowds frequent the seashore. It may be effective in other ways, but its chief object, at the present time, is to officially collect the facts, establish the evidence of neglect, and thereby procure the passage and enforcement of stringent laws for the protection of the public health. The travelling public have the right to appeal to the central authorities for protection when not elsewhere afforded. Of themselves, they are helpless. To trust to the local authorities is, as a rule, useless and a false dependence, as past and present experiences have proved. The cupidity of land associations, and speculators in lots and houses, and of proprietors of hotels and boarding-houses must be opposed by the enforced observance of the fundamental principles of sanitary law. If the State Board of Health is not vested with the required authority, it is competent for it to conduct searching inspections, the results of which will form the basis of the required legislative action.

The status of the population and government of summer resorts is a peculiar one. In most cases, the very existence of the place depends on the presence of a transient population, derived from all parts of the country, whose pursuit is recreation, rest, and health; and it is from this patronage that the permanent population, for the most part, derives its livelihood. But it is the meagre number of permanent inhabitants who appoint the government, and regulate the internal affairs. From the very nature of the case, it is not possible for the great mass of temporary sojourners, many of whom have property interests involved, to participate in the regulation of local government. This, therefore, is a valid reason for the interference of the legislature for the protection of the health of citizens and guests from all parts of the commonwealth who frequent these localities for their natural advantages, but who are powerless to guard themselves against the evils of maladministration of sanitary government.

No better service could be performed by the State Board of Health than that of periodical inspection of the drainage and sewerage arrangements, the methods of the removal of refuse, and the character of the water-supply, and the publication of the results so obtained for the information and guidance of the public, and for the cultivation of enlightened public opinion on this vital subject. Public opinion, which eventually moulds itself into law, prepares the way

for the intelligent and willing observance of the law. Self-interest is always on the alert to catch the indications of the dominant views of the community, and wisely acquiesces in their demands. It is therefore of the highest importance to instruct the public in the fundamental principles of sanitary law, to point out the evils which result from its violation, and to show how they may be guarded against. In this work the medical and secular press have a noble function to perform, and it is a favorable indication that this exalted mission is not being neglected. The tracts on sanitary topics issued by the various State boards of health are a specific and pointed illustration of this method of disseminating useful information.

A means of accomplishing much good, which is specially applicable to summer resorts, is through the enterprise of the so-called Sanitary Protective Associations, such as that recently organized in Newport and other places. The advantages of co-operation accrue not only directly to individuals, who by this plan are enabled to obtain the best advice upon the sanitary arrangements of their houses and premises at a nominal cost, but indirectly to the general public by the influence which an organized body with distinctive aims exerts in suggesting, developing, and urging measures intended for the sanitary well-being of the entire community.

It is time that a public protest were entered against the culpable indifference and neglect exhibited in matters which so radically affect the public good, and that every other justifiable means should be resorted to, to compel the correction of gross abuses in refuse removal, sewerage, and water-supply at most of the watering places along the sea coast in this vicinity. The practice, with few exceptions, of depositing all the excreta, and kitchen and other house wastes close to the dwelling, in shallow pits or cesspools, which are constructed with the object of securing a rapid absorption by the soil of the fluid portions of their contents, must be forever prohibited. These reservoirs of filth (which, in the absence of other modes of sewage disposal, become necessary appurtenances to every lot of ground) are nuisances of the most serious character, defiling the air, polluting the soil by soakage, and contaminating the water-supply by a possible leak into the wells or cisterns which are built underground at no great distance from the storage pits. It does not require any great effort of the imagination to picture the condition of the soil into which, within narrow limits, the sewage of a large population is daily deposited.

Pure air, pure water, and a pure soil, are the indispensable requisites of a salubrious locality. In the absence of any one of these lurks danger. Which of the numerous summer resorts that press their advantages before the public can, with truthfulness, lay claim to the possession of these fundamental qualifications?

A DEATH FROM CHLORAL.

At a hotel in Baltimore, a few days ago, a young lady died from an overdose of chloral. Melancholy was the impulse leading to the suicidal act. How far a persistent chloral habit influenced the mental state does not appear in the records of the inquest. It has been clearly established that the suicide was not driven to this fell purpose by the influences which, under ordinary circumstances, determine self-destruction. She belonged to a good family, and did not experience the hardships, the want of food and clothing, etc., which drive so many to commit suicide. There is no reason to suppose that any moral causes influenced her purpose; there is no history of disappointment, of chagrin, or of apprehension. She was addicted to the use of chloral. She had been wakeful from nervousness, and chloral afforded relief. This agent, which seemed to be a friend in time of need, proved to be a Nemesis, and demanded a penalty for the temporary relief which it afforded from time to time. The continued use of it brought on a hypochondriacal state, and, as one of the witnesses at the inquest stated, "an occasional flighty condition of the mind." The prescription in her possession enabled her to procure the drug in any quantity. When the prescription was filled she had it returned to her, or a copy made for her own custody. She was, also, in the habit of having the quantity directed in the prescription doubled or quadrupled. It happened in this way, that on a certain Sunday morning she had accumulated a no less amount than 44,000 grains of chloral. After an unusually cheerful day, filled up by attendance at church, conversation with the guests in the house, etc., she carried out her purpose deliberately on retiring for the night. At bed-time she was accompanied to her room by a lady friend, and then, as had been their custom, a chapter in the Bible was read, and prayers followed. Ten minutes after her friend had returned to her own room, adjoining, she heard some one fall heavily. The suicide had swallowed a tumblerful of the chloral solution, instead of a teaspoonful, the proper, but large, dose, and in response to an inquiry said, before becoming unconscious, "it's all right."

Several notable points are contained in the verdict of the coroner's jury. They find that the suicide "came to her death from an overdose of chloral administered by her own hands, . . . but whether with suicidal intent we are unable to say, though the evidence before us tends to show she may not have been in her right mind." They also

"severely condemn the improper use of a physician's prescription by the druggists, who, without his authority, greatly multiplied the quantity."

The verdict implies that the act, if suicidal, was committed whilst in a deranged state. This is the humane way in which suicide is regarded by the public and by coroners' juries. Life is held to be so precious a possession that no one surrenders it voluntarily without being

"—— To dumb forgetfulness a prey."

The history of this case, as shown in the evidence given before the coroner, indicates a settled purpose; the material for self-destruction was carefully collected, and interference of others in her deadly act prevented by an assumption of cheerfulness. If she may at times have exhibited a flighty mind (chloral intoxication), there was no evidence of such a state during the course of that fatal Sunday. All her acts were logical and sequential, and the suicide was a deliberate purpose, to the performance of which, however, she was driven by a despairing sense of her thraldom, and by the profound melancholy induced by chloral.

The other important question raised by the verdict of the jury, is the right of physicians in their prescriptions. The jury condemned the druggists for not confining themselves to a literal interpretation of the prescription, thereby implying their conviction that the pharmaceutist is limited to the terms of the prescription and cannot modify it in form, or increase the quantity. They imply further, that pharmaceutists have no right "to renew" the prescription without the approval of the physician. The druggists censured have not failed to protest against the opinions of the coroner's jury. We believe that there are judicial decisions, not in harmony with this verdict—that the right in a prescription resides with the individual paying for it. But, clearly, the result in this case should be a warning to pharmaceutists in regard to furnishing a larger quantity of a poisonous substance than is directed by the prescription.

SPINA'S REPLY TO KOCH.

HAVING published the most important parts of Koch's caustic reply to Spina's criticism of his experiments upon the "Etiology of Tuberculosis," we think it but fair, even at the risk of tiring our readers, that Spina should be heard in reply. Spina expects to answer Koch in a special publication, but in *Wiener Med. Presse*, March 25th, replies to two of Koch's most emphatic objections.

Thus, it will be recollected that Koch charges Spina with adding to preparations, in which his object was to demonstrate tubercle-bacilli, saliva (which abounds in bacteria), and gives the reader the impression that he has ignorantly contaminated with saliva all his preparations. In point of fact, Spina moistened the cover-glass in two instances only, with the saliva of a healthy person, thoroughly knowing what he was about. In these instances he was seeking for the bacilli in the cheesy contents of cavities, found the material would not adhere to the cover glass, and sought to aid this adhesion by using the saliva as stated, for the reason that the sputum of phthisical patients is often mixed with saliva without in any way interfering with the bacilli, and because Koch *distinctly states that tubercle-bacilli do not occur in the saliva of healthy individuals*, and that the bacilli found in saliva differs *toto cælo* from the real tubercle-bacilli. He says, further, that the preparations in which he found the thick rod-bacteria, which Koch says owe their origin to saliva, *were not treated with saliva.*

Second, as to Spina's culture experiments. In order to prevent the transfer to the gelatine on which the tubercle-bacilli are cultivated, of decomposition-bacteria, he brushed from certain poppy-seed-sized omental tubercles, the adhering fluid—using for the purpose a brush which had lain for a long time in a solution of corrosive sublimate, then washed with hot water, and dried in a disinfected glass tube closed with cotton. The tubercles were placed upon a heated object-glass with a pair of heated forceps, and brushed off with the sterilized brush. This entire manipulation Spina did not consider necessary to describe in his original paper, as it is known to every mycologist how a disinfected brush should be dried, that all instruments should be sterilized by heating, etc.

Koch, in his reply, charged Spina with having applied corrosive sublimate directly to the tubercle, whereas Spina expressly said that he used a *dry brush disinfected by corrosive sublimate.*

Again, Koch insists that Spina should have pursued his (Koch's) method, which was to wash the surface of the tuberculous organ with corrosive sublimate, to remove with heated knives the superficial layers thus washed, and to take the inoculating material out of the interior of the lung. But the tubercle treated was the size of a poppy-seed, and yet it was to be washed with corrosive sublimate solution, and have its superficial layers scaled off! Such an application of corrosive sublimate, to a tubercle of such size, says Spina, would penetrate to its centre and destroy all bacteria, including the tubercle-bacilli as well.

It will be seen, therefore, that Spina is taken to task by Koch for a certain procedure, and again taken to task for omitting the same procedure, under circumstances, when to have carried it out would have retarded the experiment.

It is on account of such statements as these, culminating in the contemptuous words, "in such

manner are pure culture-experiments made in Stricker's laboratory," that Spina charges Koch with carelessness in his criticisms, and it would seem, with a certain degree of propriety.

ACETONÆMIA.

IN the death by coma, which is one of the modes by which diabetes terminates, there are many cases in which no lesion is discoverable. An acute coma is produced in such cases by the sudden development of acetone in the blood—hence the term *acetonæmia*. It can be detected free in the urine in cases of diabetes, but it appears to exist in the blood in the form of aceto-acetic acid, which readily yields acetone. The circumstances under which this conversion of aceto-acetic acid into acetone takes place in cases of diabetes is not well understood. Aceto-acetic acid is a product of the alcoholic fermentation of the glucose, and, hence, the acid condition of the blood in diabetes is explained.

According to Dr. Ralfe, there is a striking similarity in the symptomatic expression and in the morbid changes between acetonæmia, acute yellow atrophy, and acute phosphorous poisoning. If a sudden accumulation of acetone takes place in the blood, either because of its excessive production or because its excretion is prevented, delirium, convulsive movements ending in profound coma come on, and the changes found post-mortem consist in acute fatty degeneration of the liver and other organs.

Opposed to this view of the constant presence of post-mortem changes, which ally acetonæmia to acute yellow atrophy and phosphorous poisoning, are the statistics of the deaths from diabetes, collected from the records of the London Hospital for eight years. Dr. Stephen Mackenzie, who has submitted these figures, gives the number of deaths from coma as nineteen, out of thirty-seven deaths in all, of which there were seven that presented no post-mortem evidences of disease. Erroneous or imperfect observation must be suspected here, since Dr. Mackenzie admits that in one of eleven cases there was fatty degeneration of the liver found, and in the others of this group there was atrophy of the liver cells. These eleven cases constituted one-third of the whole number of fatal cases examined after death.

Acute diabetic coma is not always due to acetonæmia. To the sudden production of fat embolisms has been ascribed the comatose state in some instances. So far as Dr. Mackenzie's observations are concerned, however, fat embolisms, as a cause of coma, must be regarded as doubtful. Another lesion which may have some relation to the sudden production of coma, is a degenerative atrophy of the heart, noted by Mackenzie in some cases. This observation has also been made by Schmitz, who finds that an atrophic change takes place in the muscles of the body generally, including the heart, and to this he refers some of the cases of sudden death ascribed to acetonæmia.

It may be desirable to state that the most easily applied test for acetone is ferric chloride. To the urine suspected to contain acetone, solution of the chloride of iron is added, drop by drop, when a deep reddish-brown color is produced, if the acetone be present. A more complicated reaction is the formation of iodoform (iodide of formyl), when acetone is present, by the action of iodine. This test is based on the usual process for obtaining iodoform, by the reaction between iodine and alcohol producing iodoform.

WE observe with regret that our Paris contemporary exhibits an envious disposition towards American medical talent. All the world now knows—thanks to an industrious post—of a monograph on "The Therapeutic Action of Potassium Chlorate," according to which, *Le Progrès Médicale* says "we are in the presence of a universal panacea." After enumerating the maladies reported to be cured in the pamphlet aforesaid, by the chlorate, the unbelieving journalist remarks that "the therapeutic mission assigned to this medicine is too beautiful to be real, and must exist only in the imagination of the American physician making the discovery."

WE have received a price-list of "Tablet Triturates," manufactured by a well-known firm of homœopathic pharmacists, which might well make the bones of poor Hahnemann shake in his coffin. Think of the $\frac{1}{20}$ gr. of arsenic, the $\frac{1}{50}$ gr. of aconitine, atropine, or digitaline, a grain of calomel, the $\frac{1}{4}$ gr. of morphine, and $\frac{1}{10}$ gr. of biniodide of mercury! Not that we object to such doses, with the exception of the last which is dangerous in amount, but it is the reconciliation of such doses with the hypothesis of infinitesimals that puzzles us. Dr. Piffard and Dr. Fuller are quoted in support of this method of administration, and their articles in the *Medical Record* are the only ones, apparently, that have been re-published, and will be furnished "gratis on application."

THE fourth annual meeting of the American Surgical Association, representing nearly one hundred of the most prominent surgeons of the country, will take place at Cincinnati on Thursday, May 31st, and continue for three days. The meeting held in Philadelphia last June was a decided success; and, judging from the number and character of the papers to be read at Cincinnati, the meeting there will be still more interesting. The meeting will be held under the presidency of Dr. Samuel D. Gross.

SOCIETY PROCEEDINGS.

SOUTH CAROLINA MEDICAL ASSOCIATION.

Thirty-third Annual Session, held at Yorkville, April 25 and 26, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE thirty-third Annual Meeting of the South Carolina Medical Association was held at the Court House, Yorkville, April 25 and 26, the *President*, F. F. GARY, M.D., in the chair. The attendance was fair, and seventeen new members were added to the roll.

THE PRESIDENT choose for the subject of his address,

THE STATE BOARD OF HEALTH, AND THE DUTY OF THE STATE TO AID AND SUPPORT IT.

Heretofore, the labors of the medical profession have been chiefly directed to acquiring a knowledge of the causes of disease, the better to cure it; but it has been reserved for the present century to organize and create a distinct department of medicine for the prevention and extinction of disease, known as Hygiene, or Sanitary Science. The preservation of health is not only a higher object, but a totally different one from the cure of disease; and this Association can boast of no more important act than the one securing the organization of the State Board of Health. The Act of the Legislature constitutes this Association the Board of Health of the State, and its sole adviser in all questions involving the care and protection of the public health.

In the discussions in the Legislature which preceded the organization of the Board, it was objected by some that there was no necessity for it, and even as late as the last session, an effort for the repeal of the Act was made in the Senate, but, I am glad to say, was overwhelmingly defeated. No intelligent citizen, with the sad experience before him in the history of our State of repeated epidemics, involving not only great loss of human life, but also great injury to commerce, will hesitate as to his duty. Every interest and every consideration prompt the citizen to coöperate with us in well-considered measures for public hygiene, and demand of an intelligent Legislature that it shall aid and support it; because the benefits accruing from the preservation of public health cannot be estimated.

The Act creating the Board of Health does not go far enough to accomplish all the aims and purposes of the Executive Committee. At the last session of the Legislature a bill to organize Boards of Health, and for the better preservation of the public health, was introduced, and favorably reported on by the Medical Committee of the House, and is now pending. Among the important sections of the bill is one for the collection of vital statistics. Those who are careless and indifferent to the wants of the people may raise objections and question the necessity of such a law, but it should not be forgotten that by the very Act creating the State Board of Health, it becomes "the duty of its Executive Committee to recommend such provisions of law as shall be deemed necessary for the thorough organization of a system of registration of vital statistics throughout the State."

It may be asked what interest the State has in maintaining a Board of Health? To which we have an answer in the fact that over one-half of the diseases which impose such a heavy tax upon us may be prevented by an observance of sanitary measures. The Board of Health should be required to give the necessary information, and the State must enact and enforce the necessary laws for the prevention of disease. The result of such legislation elsewhere has been to improve the human condition. The average duration of life has been increased, epidemics have been moderated, contagion has been circumscribed, and morbific agents subdued. In England, by proper sanitary regulations, the death-rate has been reduced over twelve per cent. in urban, and over eight per cent. in rural districts.

The State, in supporting the State Board of Health, will not be making a new departure, but will simply realize the aphorism of a Beaconsfield, "The health of the people is the first duty of the statesman."

THE NATIONAL BOARD OF HEALTH.

The following resolutions, submitted by Dr. T. G. SIMONS, *Chairman of Committee on Quarantine*, were unanimously adopted:

"*Resolved*, That the South Carolina Medical Association, in its corporate capacity as the State Board of Health, does hereby express its continued confidence in the National Board of Health, for its wise and beneficent efforts to secure sanitary reform and to maintain public hygiene, and that it fully appreciates the benefits conferred upon the whole country by the 'Emmigrant Inspection Service;' also, that by its general scientific investigations and reports upon the causes of disease, the National Board of Health has proved, to the satisfaction of sanitarians, its eminent ability to perform the great work entrusted to it. More especially does this Association commend the system of national quarantine refuge stations and inspections as conducted by this Board; and endorses the Board as better qualified to conduct this important work than any other department of government service.

"*Resolved*, That this Association does most earnestly urge upon and request his Excellency, the President, to empower the National Board of Health to open and conduct the National Quarantine Refuge Station at Sapelo Sound, and to furnish the Board with such part of the fund apppropriated by Congress 'to prevent the spread of epidemic diseases' as may be requisite for this purpose during the coming summer and autumn.

"*Resolved*, That in the opinion of this Association, it is essential to the safety of our seaports and to the perfecting of our quarantine system, to have this station as a resort for infected vessels bound to the South Atlantic ports. Sapelo Station, being remote from populous trade centres, offers a safe refuge where the sick and distressed seaman can be humanely treated without danger of spreading disease and desolation to crowded communities.

"*Resolved*, That a copy of these resolutions be sent to his Excellency, the President of the United States, and also to the National Board of Health."

THE DISCOVERY OF ANÆSTHESIA.

DRS. BRATTON, TAYLOR, and TABER, the committee appointed to "investigate the claims of the original discoverers of the anæsthetic properties of sulphuric ether, and the successful application of the same in surgical operations," presented a report in which, after some prefatory remarks, they say that the claimant who appears first in this case is P. A. Wilhite, who makes a statement, based upon affidavit, and this testimony of P. A. Wilhite is fully corroborated by the affidavit of Sam. B. Wier, to the effect, that he was present at the house of John Wier, in what was called an ether frolic, and he there saw a negro boy put to sleep with sulphuric ether, administered by P. A. Wilhite, now of Anderson, S. C.

This affidavit is corroborated by the affidavit of Mrs. C. Wier, of Clark County, Ga., Dec. 12, 1882, recounting the same facts.

The history of medical literature nowhere gives us the information of such an effect having been produced

previous to this date by sulphuric ether in the hands of any person, either in this or any other country.

The claimant who next appears is Dr. Crawford W. Long, of Athens, Ga. His claim is supported by the testimony of Dr. Whilhite, already given, and the affidavit of Mr. Jas. M. Venable, the gentleman upon whom Dr. Long operated, for the first time, under sulphuric ether; also by the publication of Dr. Charles T. Jackson, in the *Boston Medical and Surgical Journal*, April 11, 1861.

A statement by Dr. Long, published in the *Southern Medical and Surgical Journal*, Dec. 1849, is cited, in which he says that the first patient to whom he administered ether in a surgical operation was Mr. James M. Venable, on the 30th March, 1842. That he again operated on the same patient under ether June 6, 1842. This is corroborated by an affidavit of Mr. Venable, the patient, dated July 23, 1849. Dr. Wilhite states that the etherization of Venable was as complete as it is ever made nowadays, and that Venable always declared that he felt no pain during the operation.[1] Dr. Long also operated under ether July 3, 1842; Sept. 9, 1843; and Jan. 6, 1845.

Then follows a statement of Dr. Charles T. Jackson, published in the *Boston Medical and Surgical Journal*, April 11, 1861, recognizing Long's claim to be the first to produce anæsthesia (by etherization) for surgical operations; also a statement of Dr. Marion Sims, corroborating the same opinion, and contributing some interesting details in the history of the discovery and development of anæsthesia by ether. Amongst other things, he shows that, on the 16th and 17th of October, 1846, Morton gave ether in the Massachusetts General Hospital to patients who were operated on by Drs. Warren, Hayward, and Bigelow, and from that time it came rapidly into use by the whole profession.

From a view of all the facts the Committee draw the following conclusions: That for more than fifty years the inhalation of sulphuric ether as an excitant has been common in some parts of Georgia, though not practised in the colleges. 2. That Wilhite was the first man to produce profound anæsthesia, which was done accidentally with sulphuric ether in 1841. 3. That Long was the first man intentionally to produce anæsthesia for surgical operations, and that this was done with sulphuric ether in 1842. 4. That Long did not by accident hit upon it, but that he reasoned it out, in a philosophic and logical manner. 5. That Wells, without any knowledge of Long's labors, demonstrated, in the same philosophic way, anæsthesia by the use of nitrous oxide gas in 1844. 6. That Morton, desiring to use the gas in dentistry, asked Wells to show him how to make it in 1846. 7. That Wells referred Morton to Jackson, as the latter was a scientific man and an able chemist. 8. That Jackson told Morton to use sulphuric ether instead of gas, as it possessed the same properties, and was as safe, and easy to get. 9. That Morton, acting upon Jackson's suggestion, used the ether successfully in the subtraction of teeth in 1846. 10. That Warren, Haywood, and Bigelow performed important surgical operations in the Massachusetts General Hospital, October, 1846, on patients etherized by Morton, and that this introduced the practice throughout the world.

Wilhite, the last and only survivor of those laying claim to the honor of this invaluable discovery, still lives and moves among his professional colleagues, wearing with honor, grace, and dignity the insignia of his profession, which he so highly appreciates and ardently loves; calmly, patiently, silently awaiting the dispensation of that honor, equity, and justice due from a grateful people.

[1] Morton's anæsthesia with sulphuric ether was on Sept. 30, 1846.

DR. A. A. MOORE read a paper on

CHLOROFORM AS A CAUSE OF POST-PARTUM HEMORRHAGE.

While chloroform was generally administered in this country to annul the suffering of the parturient woman, he believed that its agency in producing post-partum hemorrhage was not so generally recognized as it should be. Assuming its causative relation to such hemorrhage, were we justified, he asked, in resorting to it merely to abolish the pangs of ordinary labor? In his own practice he was in the habit of giving it, if requested, but never insisted on it. In its administration he had been long governed by Playfair's rule, to give it only in the propulsive stage and intermittently, never giving it to complete anæsthesia. But even thus he had found its use attended with so much uterine inertia, as to be obliged to withhold it for a time to allow a return of the force and frequency of the pains. It was this very inertia after delivery which predisposed to post-partum hemorrhage, and during the last few years he had met with this unpleasant complication several times, when he could attribute it to no other cause than the inhalation of chloroform. He gave the following analysis of thirty-four cases of labor attended during the years 1881 and 1882, as going to substantiate his views. In twenty cases chloroform was administered; in four of these there was free hemorrhage, in thirteen there was less, but more than natural, and in three there was no report. In fourteen cases there was no chloroform administered. Of these, only two had hemorrhage; with one it was habitual, the other was a woman who had borne children rapidly, was quite fleshy, having the abdominal walls pendulous and flabby, giving no support to an inert uterus.

He then cited various authorities, some in favor of the use of chloroform in labor, but all with a word of caution against its tendency to cause uterine inertia and hemorrhage.

A paper by JULIAN J. CHISOLM, M.D., Professor of Eye and Ear Diseases in the University of Maryland, was read, entitled

SHALL WE PUT SPECTACLES ON CHILDREN?

This question, from want of proper information, is often answered in the negative. According to tradition, the need of spectacles is an indication of old age, but a better knowledge is diffusing itself, and it is coming to be generally known that age is not the only criterion of the necessity for optical aid.

Every-day experience teaches that the human eye varies much from the type of a perfect one, viz., one with which good vision can be enjoyed comfortably, for any distance far or near, to which is given the name emmetropic. In such an eye the crystalline lens in its passive state must focus accurately on the retina, and the muscles of accommodation can make it more convex, and adapt it for condensing the light from approaching bodies, so as to keep the focus always on the retina.

What is called accommodation or ability to change the focus is a muscular act, which, by taking off pressure from the front of the lens, permits its inherent elasticity to give its surfaces greater convexity, and, therefore, greater focussing power. When these muscles are temporarily enfeebled by diseased conditions of the system at large, they do not lift off sufficiently the flattening pressure of the suspensory ligament, or they are too weak to keep up their continued action. Hence it is that sick persons, with weakened muscles, cannot read as long nor with the same comfort as when well and strong. When from feeble muscles, the convexity of the lens cannot be sustained, a magnifying spectacle for temporary use will enable persons to read, while tonics are being administered to restore perma-

nent strength. We often find children recently recovered from an attack of measles, scarlet fever, diphtheria, whooping-cough, or any one of the depressing diseases of childhood, unable to study as they did before the attack. For a little while the eyes seem as strong as ever, but a very few minutes' use will cause letters to run together, and the print becomes blurred. This is not a failure of the retina or optic nerve, but of the muscles acting on the lens. A weak magnifying spectacle, by helping the muscles to do their work, will enable weak children to continue their studies, until their strength is restored.

If children, either by inheritance or acquisition, have myopic or hypermetropic eyes, what can be the propriety of allowing them to go through life as if in a constant fog, when a properly selected glass clears up the mist, and enables them to see as others do?

Dr. T. P. Bailey, Georgetown, S. C., read a paper on

HEMORRHAGIC MALARIAL FEVER.

This disease has been familiar to the profession of Georgetown only in the past fifteen years. It seldom occurs here in the hot months, but generally late in the autumn, the most malignant cases I have observed occurred in November, December, and January.

Symptoms: A patient who has had attacks of chills and fever, but has not been regularly treated, his condition one of marked anæmia, is suddenly taken with a chill, pulse small and frequent, with or without nausea and vomiting, voids urine like black grumous blood, which, when agitated, shows a yellowish tinge on the sides of the vessel. There is great nervous excitement and tendency to collapse. Temperature seldom more than 103°. In about twelve to fourteen hours the whole cutaneous surface turns of a bright yellow hue; conjunctiva also yellowish. As the fever subsides, the skin becomes pale, and the urine resumes its usual tint, while the failure of the vital powers is more marked. This intermittent stage may last twenty-four hours, when another chill comes on with an aggravation of all the symptoms, and if these are not controlled the patient soon dies, like one in an exsanguineous condition.

The most prevalent and fatal cases are of the remittent form. Commencing with a slight chill, they are characterized by an anxious countenance, febrile remissions and exacerbations, gastric irritation, urine more or less hemorrhagic, with the exacerbations and remissions likewise; the yellowness of skin increased or diminished with the same symptoms. The more free the secretion of the kidneys, the more amenable to treatment is the disease. Under treatment, many of the symptoms may disappear; there may be almost complete defervescence; the skin may lose its icterode hue, and the urine become healthy looking, yet the patient dies rapidly of exhaustion, or suddenly in a convulsion. We have much to learn of the true nature of this disease. The system, after having been subjected to several attacks of malarial fever, is left in a cachectic condition, and a breaking down of the blood corpuscles takes place, as manifested in the secretion of the kidneys.

The resemblance of this disease to yellow fever is certainly in some cases very striking, so much so, that it has been called "Swamp Yellow Fever," but the symptoms given above are sufficient to distinguish it.

The treatment must be thoroughly supporting, with a free use of stimulants and nourishment, and the administration of stimulant diaphoretics, quinia and iron. Quinia alone appears to be of little use, and is often disappointing.

Dr. John Forrest, of Charleston, read a paper on

BOROGLYCERIDE,

a new antiseptic, a compound of boracic acid and glycerine, discovered by Prof. Barff, of London. It is prepared by heating sixty-two parts of boracic acid in ninety-two parts of glycerine, to a temperature of about 300° F., until the mass ceases to lose weight. On cooling, it sets like glue, and is soluble in water. A solution in water or glycerine makes a most valuable antiseptic fluid. Cotton tampons, steeped in a strong solution, may be left in the vagina a week, without becoming offensive or causing any annoyance to the patient, except sometimes a little dryness of the tongue. It is thoroughly antiseptic and perfectly harmless, which is more than can be said of either carbolic acid or iodoform. It has been used in some of the London hospitals, in surgical dressings, with most satisfactory results. It has proved beneficial in diphtheritic sore throat, and in ulcers of the mucous membranes. In purulent ophthalmia it has been highly recommended. For preserving anatomical specimens it is far superior to alcohol, as it does not shrivel up the tissues. In every respect, it promises to be a most invaluable addition to our list of antiseptics.

After the reading of a number of more papers, the following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. R. A. Kinloch.

Vice-Presidents.—Drs. A. A. Moore, J. Ford Prioleau, and T. Munro.

Recording Secretary.—Dr. John Forrest.

Corresponding Secretary.—Dr. H. D. Fraser.

Treasurer.—Dr. H. W. De Saussure, Jr.

The Association adjourned to meet at Florence, April 22, 1884.

MEDICAL ASSOCIATION OF GEORGIA.

Third Annual Session, held at Athens, April 18 and 19, 1883.

The meeting was called to order by the *retiring President*, Dr. William F. Holt, of Macon.

A letter was read from the *Secretary*, Dr. A. Sibley Campbell, of Augusta, regretting his unavoidable absence from the meeting, and Dr. James A. Gray, of Atlanta, was requested to act as Secretary *pro tem.*

Dr. John Gerdine, in behalf of the Committee of Arrangements, delivered the *Address of Welcome*, which was responded to by Dr. James B. Baird, of Atlanta, in behalf of the Association.

Dr. William F. Holt, then introduced the *President-elect*, Dr. K. P. Moore, who delivered the annual address taking for his subject "Æstheticism in Medicine."

Letters from various absent members were read, expressing their regrets at not being able to be present.

Twenty-two applications for membership were read, referred to the Board of Censors, and being favorably reported upon, the applicants were duly elected.

The reports from the Standing Committees were then received, and several communications were received.

An amendment to the By-Laws was adopted, requiring the Secretary to publish the volume of *Transactions* within four months after the meeting.

On the second day, *The Nominating Committee* made the following nominations for

OFFICERS FOR THE ENSUING YEAR,

which were duly confirmed by the Association:

President.—Dr. A. W. Calhoun, of Atlanta.

Vice-Presidents.—Dr. R. J. Nunn, of Savannah, and Dr. M. P. Deadwiler, of Elberton.

Secretary.—DR. JAMES A. GRAY, of Atlanta.
Treasurer.—DR. E. C. GOODRICH, of Augusta.
Additions to the Board of Censors.—DR. EUGENE FOSTER, of Augusta, and DR. J. S. TODD, of Atlanta.

Macon was selected as the place of meeting next year.

The Association adjourned to meet in Macon next year, on the third Wednesday (16th) in April.

MISSISSIPPI STATE MEDICAL ASSOCIATION.

Sixteenth Annual Session, held at Meridian, April 4, 5, and 6, 1883.

(Specially reported for THE MEDICAL NEWS.)

(*Concluded from p. 517.*)

APRIL 5TH, SECOND DAY.—MORNING SESSION.

THE form of Charter presented by the committee was adopted without amendment. The Constitution and By-Laws were considered section by section, and were amended in several important particulars.

Drs. Johnston, Kells, and Craft were appointed a committee to devise and to procure a seal for the Association.

DR. R. S. TOOMBS, of Greenville, read a report of a case of

GIN-SAW INJURY OF HAND, FOREARM, AND ELBOW-JOINT,

in which a negro boy had a hand cut to pieces, the bones of the forearm almost entirely denuded, with the skin and muscles hanging in shreds; the elbow-joint was opened, and all the arteries except the radial divided. The boy's mother would not suffer the arm to be amputated. The patient was accordingly anæsthetized, and after all fragments that seemed to be utterly destroyed had been removed, strip after strip of muscle and skin was straightened out, and the parts were coapted in the best manner possible, not less than forty sutures being required. Adhesion strips were applied where they could be used, and the whole arm was enveloped in lint saturated with carbolized oil, which was left undisturbed until suppuration set in. The boy recovered with an arm that will be of considerable service to him.

The paper was discussed by Drs. Gnice, Halbert, Green, Ward, Sale, Hancock, Hill, and Toombs.

DR. B. F. WARD, of Winona, said that owing to the rich arterial and nervous supply of the upper extremities, reparation would take place in the most unpromising cases, and that amputation would rarely be found necessary.

DR. E. P. SALE, of Aberdeen, remarked that a single case could not establish a precedent, and, by way of caution, he narrated the history of a case similar to the one described by Dr. Toombs, in which an attempt had been made to save the arm, but gangrene occurred and death was the result. He thought that where there is severe laceration of the soft tissues, and the nerves and arteries of the arm are divided, the safer course would be to amputate.

There was a difference of opinion between two of the speakers in regard to the nature of a gin-saw wound—one contending that it should be classed as an *incised*, and the other as a *lacerated*, wound.

The Association adjourned till 2.30 o'clock.

AFTERNOON SESSION.

DR. JOHN BROWNRIGG, of Columbus, exhibited a novel and effective

APPARATUS FOR SECURING COUNTER-EXTENSION IN FRACTURE OF THE FEMUR,

which seemed to possess many advantages. He exemplified its application before the Association, using, in connection with it, an apparatus very similar to Buck's, to secure extension. The following is the description of the apparatus: "A jacket closely fitting the chest is substituted for the usual perineal band. The jacket is thus constructed: Two thicknesses of unbleached domestic of good quality, wide enough to reach from the axilla to a point an inch and a half below the lower margin of the ribs, are passed around the body and brought together in front. Tapes six inches long are sewed securely to the edges, at intervals of an inch, from top to bottom, at such a distance from its edges as to make the jacket fit tight when the tapes are tied together. To make the jacket fit the form a plait is sewed on both sides diminishing in width from below upwards, and extending upwards as far as necessary. A strap with a buckle on one end, of the same material as a tourniquet-strap, is sewed by a row of stitching on both edges to the outside of the jacket, just above its lower margin, so as to admit of buckling the strap on the outside of the jacket in front. Four straps, made of strong domestic, two inches wide, are securely sewed to the upper edge of the jacket, two in front, and two behind between the neck and shoulders, long enough to tie to the head of the bedstead at points wide enough apart to allow free turning of the head, and high enough to slightly lift or support the shoulders.

"A band about four inches broad should also be applied around the pelvis and secured to the right side of the bedstead, to keep the body and the fractured limb in a line. This pelvic band should be secured to an upright piece of plank fastened to the side rail of the bedstead, extending about a foot above the side rail, with two holes near the top, one a few inches lower than the other, and the upper end of the band should be passed through the lower hole, and the lower end through the upper hole, so that when the band is secured properly, it will help to support the body, causing it to lie more lightly on the bed. This band, the counter-extending bands secured to the head of the bedstead, and the extending cord, being all somewhat elevated, the whole body lies lightly on the bed, and bedsores are prevented."

DR. J. M. TAYLOR, of Corinth, exhibited three interesting pathological specimens: a large adenoid tumor, which he had successfully removed from the left side of the face and neck of a young boy, its chief site being in the immediate vicinity of the parotid gland; a supposed villous tumor of the rectum, with a broad and well-defined pedicle; and an unbroken dysmenorrhœal membrane, that formed a perfect cast of a *uterus bicornis* which, the Doctor stated, had borne one child. The Doctor, having prepared no written report, merely gave a verbal history of these specimens.

DR. E. L. MCGEHEE, of Woodville, read a paper on

PERTUSSIS,

the subject having been assigned him by the Committee on the Selection of Special Topics, at the previous annual session.

DR. JOHN BROWNRIGG exhibited an apparatus which he had invented for the treatment of

BARTON'S FRACTURE OF THE RADIUS.

Its construction is thus explained: "The elbow should be flexed at a right angle, and the forearm placed in front of the body, with the thumb upward. A piece of strap iron, three-fourths of an inch wide, and thick enough not to spring or bend at the elbow when in use, should extend from near the shoulder along the inside of the arm to near the elbow (where it should have a round curve, so as to avoid pressure on the inside of the elbow); thence it should extend along the upper side of the forearm to the wrist, where

it should be bent slightly upward over the thumb, to avoid pressing the hand downward; thence it should extend to the end of the fingers, and the last three inches be bent downward at a right angle, at the end of the fingers. A tar-board splint should be moulded to fit the arm from near the shoulder to near the elbow, wide enough to envelop more than half the arm. This splint should be secured to the arm-portion of the iron splint by two copper rivets, and secured to the arm by a many-tailed bandage, with the ends tied together over the splint. A tar-board splint should be made to fit the forearm, to reach from near the elbow to the wrist, and wide enough to envelop half of the forearm. This splint should be secured to the iron strap by pieces of sheet iron riveted to the splint with copper rivets, so that the tar-board splint can slide on the iron strap, towards the elbow or wrist, in such a manner that the carpal end of the splint may be made to press at any point near the end of the radius where pressure is most required at the point of fracture. This is secured in the same manner as the arm splint, but another bandage may be required at the point of fracture, and in cases in which the lower end of the ulna is dislocated and displaced, a rubber bandage may be found useful. A band about three-fourths of an inch wide, of some inelastic material, is passed around the wrist where it joins the hand, and sewed so as to fit tightly. To the edge of this band next to the hand should be sewed two metal loops (like those for securing Barwell's artificial muscles for treating varus in new-born infants), one on the dorsal, and one on the palmar side of the hand. A strong cord should be attached to each of these loops and tied over the bent end of the iron splint beyond the end of the fingers, tight enough to cause sufficient extension in the axis of the arm. Strong extension and counter-extension is required to overcome muscular contraction and displacement of the fractured bones. These are obtained by the application of this splint. Lateral pressure may be applied to the fractured bone, or the lower end of the ulna, as may be required, by bandages.

EVENING SESSION.

The Committee on Nomination of Delegates to the American Medical Association presented their report, which was adopted.

DR. W. E. TODD, of Clinton, read a report of a case of

HYSTERICAL CONVULSIONS,

consequent, in his opinion, upon anteflexion of the uterus and cervical endometritis. The woman was reduced to the verge of the grave; and after the usual treatment, comprising a great variety of remedies both constitutional and local, had failed—after change of scene, and residence at health resorts had been tried without benefit—she was entirely restored to health by the systematic application of the galvanic current.

DR. E. P. SALE deprecated the use of chloral hydrate in these cases, because it tended, without compensating remedial power, to induce the terrible habit of chloralism. His remarks on this point were striking and emphatic. He favored the use of potassium bromide.

DR. B. A. VAUGHAN alluded to the views which he had formerly enunciated in a paper, published in the *Transactions* of the Association for 1874, to the effect that ovarian irritation is usually the source of uterine disease, and the consequent functional troubles; and that the motto of the gynecologist should be, *Propter ovarium*, and not *Propter uterum*. He condemned the use of bromide of potassium in these cases, because he thought its powerful sedative and paralyzing influence on the spinal nervous centres—an influence that might be so great as to induce, for instance, complete anæsthesia of the fauces, and to impair, if not to destroy, the erotic sense—would ultimately result in harm.

DR. SALE replied that the very reasons assigned by Dr. Vaughan in condemnation of the potassium bromide, were to him arguments in its favor.

DR. MABRY read a paper on

PUERPERAL CONVULSIONS,

which was discussed by Drs. Guice and McCallum.

DR. GUICE reiterated his views, which had been fully set forth by him in a paper published in the last volume of the *Transactions* of the Association, in regard to the remarkable efficacy of *Veratrum Viride in Puerperal Convulsions*.

DR. A. G. SINCLAIR, of Memphis, Tenn. (who had been elected a member of the Association), read an interesting paper on

GLIOMA OF THE RETINA,

in which, after reviewing fully the pathology and treatment of this formidable affection, he narrated the history of a patient on whom he had operated successfully. Although several months had elapsed, there was no indication of a return of the disease.

In reply to a question, Dr. Sinclair stated that the disease would probably recur. He had, however, known a case in which there was, after operation, a period of exemption for seven years.

DR. JOHN BROWNRIGG read a brief report of a case in which he performed the operation of

EXTERNAL URETHROTOMY.

The patient was a negro man, with a stricture through which the smallest bougie could not be passed. An abscess discharging pus, through which urine trickled, was situated on top of the penis, near its junction with the pubis above the stricture. There were great induration and swelling of the penis around the abscess. On attempting to urinate, only a few drops escaped from the meatus, as well as the fistulous opening. There was constant dribbling from both places, with characteristic odor. The patient was reduced in flesh, with painful facial expression. After several efforts, Dr. B. succeeded in passing the smallest bougie, strengthened by a small wire, through or nearly through the stricture, which was an inch in length. He slipped over this, down to the stricture, a larger bougie with the end cut off. Guided by this larger bougie, he cut down on the urethra, and split it for one and a half inch, when he found an open canal on both sides of the stricture. He closed the wound by sutures and adhesive plaster, which soon gave way, and the urine flowed freely through the cut. This closed by granulation in ten days, and, on introducing a No. 12 bougie, American scale, a good urethra was found to be reëstablished.

APRIL 6. THIRD DAY.—MORNING SESSION.

DR. G. W. TRIMBLE, of Grenada, who had been elected orator at the last session, being unable to appear, had forwarded his *oration* in MS., which was now presented, and referred, unread, to the Committee on Publication.

DR. J. Y. MURRY, of Ripley, offered the usual resolutions of thanks, which were unanimously adopted.

The Association then proceeded to the election of

OFFICERS FOR THE ENSUING YEAR,

which resulted as follows:

President.—Dr. J. M. Greene, of Aberdeen.

Vice-Presidents.—Drs. S. N. Walker, of Baldwyn, and D. McCallum, of Westville.

Recording Secretary.—Dr. W. E. Todd, of Clinton.
Assistant Secretary.—Dr. J. F. Hunter, of Jackson.
Corresponding Secretary.—Dr. M. S. Craft, of Jackson.
Treasurer.—Dr. Robert Kells, of Jackson.
Judicial Council.—Drs. W. D. Carter, J. M. Taylor, N. L. Guice, R. S. Toombs, B. F. Ward, S. V. D. Hill, J. P. Moore, W. Powell, and B. F. Kittrell.

The following gentlemen were nominated for appointment by the Governor to fill existing *vacancies in the State Board of Health:* For Sanitary Commissioner of First District, Dr. J. M. Taylor, of Corinth; Fourth District, Dr. J. P. Moore, of Yazoo City; Fifth District, Dr. Robert Kells, of Jackson, and Dr. J. W. Bennett, of Brookham; Sixth District, Dr. R. S. Toombs, of Greenville.

A telegram was received from Dr. M. S. Craft, of Jackson, which stated that, finding he would be unable to attend the meeting, he had forwarded by mail his *Report on the Surgery of Mississippi.* On motion, the report was referred to the Committee on Publication.

AFTERNOON SESSION.

DR. J. T. HANCOCK, of Shuqualak, read a paper on

TRISMUS NASCENTIUM,

in which he gave a report of a case as follows: "Infant eight days old; jaw immovable; general rigidity of muscles; disposed to nurse, but could not. It made the noise between a cry and a whine, so peculiar to the disease; had been in semi-comatose condition at intervals during last six or eight hours. I immediately ordered a warm bath, and while it was being got ready administered enema, and applied the following liniment to spine:

℞.—Tinct. gelsemii,
Tinct. lobeliæ,
Tinct. camphoræ,
Ol. Olivæ, ... āā f℥ss.
Chloroformi, ... f℥ij.—M.
Sig.—Ft. lin.

Kept it in the bath about thirty-five minutes; then wrapped it in a sheet, and gave by enema five grains of bromide of potassium, and five drops of tinct. gelsemium; caused it to be retained by application of warm napkin. Applied to umbilicus one drachm of sulph. zinc to one ounce of water, using a poultice over this of powdered slippery elm, which was kept up during treatment. Kept cloths, wet in cold water, to head; gave internally two grains of bromide of potassium and two drops of tinct. gelsemium every two hours till symptoms grew better, and then diminished the dose. Kept bowels open by giving syrup of rhubarb. Five cases recovered under above treatment. Several relations, on the paternal side of the case detailed, lost children with the same disease, developing on the eighth day after birth."

DR. D. L. PHARES, of Starkville, Miss., being unable to attend the meeting, had forwarded to the Secretary an interesting report of an

EPIDEMIC ORCHITIS,

which occurred during the winter of 1880, over a considerable portion of the State. Parotitis, or mumps, was also prevalent at the time; and although there was an unusual tendency to metastatic orchitis, yet the orchitis frequently occurred as an independent affection, being apparently excited by the most trivial causes, such as a slight blow or even erotic sensations. The treatment consisted in the constant local application of equal parts of tincture of lobelia and glycerine to the surface of the tumefied parts. Relief in almost every instance was surprisingly prompt, the tumefaction usually disappearing within thirty-six hours.

DR. N. L. GUICE read a paper on the

HYPODERMIC USE OF SULPHATE OF QUININE,

in which he said that abscesses result from improper methods of giving, and unsuitable points selected for introducing the solutions. Although he had been using the acid solution for sixteen years, with a large number of patients ranging from two to sixty years of age, he had never seen anything worse than, in a few cases, a cold abscess containing a few minims of pus, which, being opened, healed readily. This success was due, in his opinion, to his method of giving the injection; which is such as to avoid laceration or even *tension* of the tissues as a result of the injection. He selects a region where the inner surface of the subcutaneous areolar tissue is loosely adherent to the subjacent tissues, as the dorsal surface of the forearm, or the front and lateral regions of the thorax or abdomen. With the thumb and index finger of the left hand, he elevates the skin and entire thickness of areolar tissue, and passes the needle entirely through these structures at a right angle to the direction in which they are held; carrying the point beneath the inner surface of the areolar tissue, and depositing the solution in the loose elastic tissue connecting the areolar with the subjacent tissues. Scrupulous care is required with subjects possessing a free development of the subcutaneous areolar tissue; for it is in these that we are liable to deposit the solution in the parenchyma of the tissue. Bartholow's method is probably the same, but he is not sufficiently explicit in his description, except for subjects possessing a very moderate development of the subcutaneous areolar tissue.

HONORARY MEMBERS.

On the recommendation of the Judicial Council, Dr. D. Sutton, of Lexington, Dr. T. J. Crofford, of Memphis, Tenn., and Hon. T. G Barry, of West Point, were elected to honorary membership.

The President announced the usual Standing Committees. A committee of three was appointed to conduct the President-elect, Dr. J. M. Green, to the Chair, who, in a few well-chosen words, thanked the Association for the honor which had been conferred upon him.

The Association then adjourned.

In the evening an elegant banquet was served in honor of the Association, by the Committee of Arrangements.

The next session of the Association will be held at West Point, beginning on the first Wednesday in April, 1884.

TEXAS STATE MEDICAL ASSOCIATION.

Fifteenth Annual Session, held in Tyler, Texas, April 24, 25, 26, and 27, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE Texas State Medical Association convened in Albertson's Opera House, Tyler, Texas, April 24, 1883. The Society was called to order by the *President*, DR. S. F. STARLEY, of Corsicana.

The session was opened with prayer. The roll of members was then called by Dr. W. J. Burt, of Austin, Secretary. All the officers answered to their names, except the Third Vice-President.

About one hundred and twenty members were present during the sessions.

DR. W. H. PARK, of Tyler, *Chairman of Committee of Arrangements*, delivered a hearty and cordial address of welcome to the Association, and Ex-Governor R. B. Hubbard, of Tyler, on behalf of the citizens, addressed the Association.

Thirty-eight new members were elected.

THE REPORT OF THE SECRETARY AND TREASURER showed amount on hand April 23, 1883, $489.91; amount collected during the session, $851.00; total balance on hand, $1,340.81.

THE COMMITTEE ON PUBLICATION recommended that the *Transactions* be published in a monthly series in the *Galveston Medical and Surgical Record*, as has been done for two years. A minority report recommending that they be published in pamphlet form, elicited quite a debate, and was finally adopted.

DR. A. R. KILPATRICK, *Chairman of Committee on Necrology*, reported the decease of forty-four physicians during the year. An examination showed, however, that but two of the number were members of the Association: Drs. H. H. Beck, of Sulphur Springs, and O. H. Leeds, of Columbus.

DR. JOHN A. WYETH, of New York, was elected an HONORARY MEMBER,

and delivered a lecture to the members on medical education, taking the ground that the course of the medical student should be at least four years. He advised a high standard of medical education, based on a good and thorough literary education.

The question was discussed by Drs. Wallace, of Waco; Clofton, of Jefferson; Nott, of Goliad; Burroughs, of Houston; and Burt and Wooten, of Austin. All were of the opinion that the Board of Regents of the University of Texas should make its medical department in every particular conform to the highest standard.

The sections were all represented by well-prepared articles, amounting to over thirty in number.

DR. T. H. NOTT, of Goliad, read an interesting article entitled the *Embryo Physician*. He also read a well-prepared essay on the *Difficulties of Tracheotomy*, reporting several successful operations in his practice.

DR. A. P. BROWN read a statement from Dr. Matthews in reference to an interesting case of *Worms Passed from the Kidneys* and through the urethra of a man for several years. The case seemed to be fully authenticated. There were two varieties of worms passed; one a reddish-brown worm about three inches long, the other a smaller worm with black *head* and *hooked bills*. The worms were often alive when discharged.

DR. JOHNSON reported the case of a CHILD MENSTRUATING AT ONE WEEK OLD and having regular monthly discharges for six years, the present age of the child.

DR. WILL B. DAVIS read a report of twenty-two cases of INTERNAL HEMORRHOIDS TREATED BY HYPODERMIC USE OF CARBOLIC ACID, thirty per cent. solution, injected into the tumors.

This article elicited quite an animated discussion in reference to the best and safest treatment for internal piles; a number preferring carbolic acid, others persulphate of iron, but quite a majority who spoke insisted on the treatment by ligature as altogether preferable.

DR. A. P. BROWN, *Chairman of the Section of Surgery*, read his report on the progress during the last year, in which he very graphically portrayed the recent advancement and improvements in surgery.

DRS. E. J. BEALL and W. A. ADAMS, of Fort Worth, reported a SUCCESSFUL CASE OF SPONGE-GRAFTING, where a large indolent ulcer of several years' standing was cured. One point of interest in the history is that this is the second successful case reported in America, and the fourth in the world, Dr. Hamilton, of Glasgow, being the first surgeon to perform this operation.

DR. D. M. RAY read a paper on FOREIGN BODIES IN THE STOMACH, based on a case in which he successfully resorted to a new method of removing a pin from the stomach, viz., by giving internally a mixture of mush and cotton, expecting the pin-point to become entangled in the cotton, and by producing emesis, have the foreign body dislodged and rejected.

DR. J. J. BURROUGHS, of Houston, reported a case of CÆSAREAN SECTION POST-MORTEM, in which the mother in labor died of convulsions, and he at once opened the abdomen and removed a living child.

A number of other interesting papers were read by caption or synopsis, and referred to the Publishing Committee.

The President's Address was a very appropriate one, and was well received.

The banquet on Thursday night was a grand one, and reflected the taste and generosity of Tyler and her citizens.

The Nominating Committee made the following report, which was adopted—

OFFICERS FOR THE ENSUING YEAR:

President.—DR. A. P. BROWN, of Jefferson.

Vice-Presidents.—DRS. T. H. NOTT, of Goliad; J. D. OSBORNE, of Cleburne; FRANK ALLEN, of Lexington.

Secretary.—DR. W. J. BURT, of Austin.

Treasurer.—DR. J. LARENDON, of Houston.

Place and time of next meeting, *Belton*, on the last Tuesday in April, 1884.

THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA.

Thirteenth Annual Session, held at San Francisco, April 18 and 19, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE Medical Society of the State of California assembled in thirteenth annual session in Covenant Hall, San Francisco, April 18, 1883.

DR. JAMES SIMPSON delivered the *Address of Welcome*, and after some preliminary business, referring to organization and credentials, DR. LANE delivered the ANNUAL ADDRESS, which consisted of observations recently made during a visit to the Republic of Guatemala.

Guatemala contains a population of one million and a quarter of inhabitants; nearly half of these are Indians, descendants of the aborigines, who are civilized. The remaining population consists of Ladinos, who are a mixture of Spanish and Indians, and besides these a small number of foreigners of various nationalities.

Pulmonary consumption rarely ever occurs among the pure-blooded Indians, but is chiefly found among the Ladinos.

Goitre is of common occurrence, being seen chiefly among the Indian women. As there is a prevalent opinion here that the cure of a goitre tends to develop scrofula, those subject to it seldom apply for treatment. Cretinism, closely associated with goitre elsewhere, does not occur here. The prevalence of goitre renders this a good place to test Chatin's theory in regard to the origin of the disease. According to him, there is an absence of iodine in the water, air, and food in the region where the disease prevails; and that

the general absence of the disease is owing to the fact that the most of the world is daily taking, in some form, a small dose of iodine, at least enough to retain their thyroid glands in decent limits. This subject is treated of exhaustively in Moleschott's *Circle of Life*, and the reader of that section is surprised at the vast array of observations which the last twenty-five years have brought in support of this theory.

In the vicinity of Guatemala there is a small colony of lepers, some fifteen in number, who are kept apart from the remaining population. The cases are found among Spaniards, who are thought to be descendants of the Moors.

DR. A. B. NIXON, Surgeon-in-Chief to the C. P. R. R. Hospital, read the

REPORT ON SURGERY.

He confined his attention chiefly to railroad surgery and insisted that rest, more than any other remedial agent, promotes reparative processes after severe injury.

DR. M. M. CHIPMAN read a synopsis of a *Report on Medicine, Topography, and Endemics.*

The Reports of the Secretary and of the Treasurer of the Examining Board were submitted to the Auditing Committee and found correct, as was also the Report of the Treasurer of the Society.

DR. A. H. PRATT presented a

REPORT ON MEDICAL EDUCATION.

In glancing over the literature of the subject he observes too great a tendency to laud the educational system of the old world, and to disparage our own.

Our system needs improvement in the following directions:

1st. We need endowed medical colleges that shall be independent of graduating classes.

2d. We need to lop the superfluous schools, as we have too many.

3d. The term of study should be prolonged.

4th. The most pressing demand for change is in the regulations for matriculation.

DR. W. P. GIBBONS read the *Report on Indigenous Botany.*

In his

REPORT ON HISTOLOGY AND MICROSCOPY,

DR. J. H. WYTHE said there is danger of the inauguration of a bacillus craze that will result injuriously to the cause of scientific truth. That a special form of bacterium has been found in tuberculous matter differing from most, if not from all others, by its capability of receiving the stain of aniline blue, there can be no doubt. But the real question, whether this bacillus is *the* cause, or only *a* cause, or merely a concomitant of the disease, is still unsettled.

DR. HIRSCHFELDER read the

REPORT ON PRACTICAL MEDICINE,

and gave an exhibition of the gastroscope.

In the year just closed, as in those that preceded it, there has been much groping in the dark, and many an *ignis fatus* has been followed as the true light of science. The use of pilocarpine has been greatly extended. In pleuritic effusion, we have found it of signal service in the City and County Hospital, large effusions disappearing over-night after the exhibition of a single dose of jaborandi. The œdema of nephritis disappears under its use; uræmia, however, may ensue from absorption of products of tissue-metamorphosis stored up in the plasma of the tissues. I have seen one such case, and numerous others have been reported. If the œdema of nephritis is not removed by pilocarpine, we may employ nitro-glycerine with great hope; the latter causes dilatation of the small arteries, and consequent reduction of blood-pressure; hence less fluid is forced out of the capillaries, and the disproportion between exosmosis and endosmosis of plasma is obviated. In arterio-sclerosis, angina pectoris, and other diseases attended by high arterial tension, it is exceedingly useful.

In mania, hyoscyamia acts with great promptitude and certainty; in paralysis agitans, it produces a temporary cessation of the tremor, to the great relief of the patient.

As an hypnotic, the tannate of cannabine is asserted to be preferable to morphia.

Kairine is a synthetic surrogate of quinine. By Filehne we are told that it invariably reduces febrile temperature without producing the slightest unpleasant symptom.

Frictional electricity is again in the field and clamoring for recognition. In cases of paralysis in which nerve degeneration has far advanced, the muscles may respond to franklinization when they are utterly indifferent to galvanism and faradism.

In pursuance of Koch's views, various antiseptic inhalations have been diligently employed, but with negative results. To destroy the bacillus tuberculosis, we must find a germicide that is innocuous to the human organism. Débove, of Paris, announces that consumption may be cured by forced alimentation. Dujardin-Beaumetz finds that nutrition is indeed improved, but the condition of the lung is generally unchanged. Little should be expected, however, from a month's trial.

Stretching of the sciatic nerve has been recommended in locomotor ataxia. I have had the operation performed in six cases: in one, a cure resulted; one died a few days after the operation in an epileptic attack; the others were not specially benefited. Within the last year, a causal relation has been tolerably well established between this disease and syphilis. Accordingly the anti-syphilitic treatment has been adopted, but without very brilliant results in cases of long standing. In a few recent cases, this treatment has been of the utmost service.

Among new inventions, the gastroscope has attracted considerable attention. How much practical benefit will be derived from the use of this wonderful instrument remains to be seen.

DR. C. M. FENN presented a supplementary report, on salicylic acid in certain phases of rheumatism.

DR. J. P. WIDNEY read a paper on the

CLIMATE AND DISEASES OF SOUTHERN CALIFORNIA.

He said, the dissimilarity between the climates of Northern California and Southern California, may be traced to a variety of causes:

1st. Difference in latitude.

2d. The eastward trend of the shore-line south of Pt. Concepcion, carries the coast away from the cold waters of the great Aleutian current; in its stead, a warmer counter-current, setting in from the peninsula of Lower California, bathes the northward shores.

3d. Inland, at a point corresponding to Pt. Concepcion, the Sierra, from its general southerly direction, turns almost due east and west, and walls out the northwest trade winds, which, cooled by their long course over the arctic current just mentioned, sweep through the many passes of the Northern Coast Range and down the great Sacramento, San Joaquin, and parallel coast valleys.

4th. The Coast Range, which, in Northern California, interposes a notable barrier between the coast and interior valleys, and makes a marked difference between their temperatures and rainfalls, in Southern California sinks to a mere geological rudiment. This breaking down of the Coast Range opens to the sea the whole

valley system of this division of the State, and makes it practically a vast system of coast valleys, with the Sierra as a background.

In consequence of its openness to the sea, the southern portion of the State, in contrast to the northern, is far better drained.

Hence, Southern California is comparatively free from malarial diseases, bronchitis, pneumonia, and pleurisy. Dysentery is not frequent; acute inflammatory rheumatism is rare, the subacute less so, while that borderland of pains, half rheumatic, half neuralgic, here, as over the whole Pacific Coast, are marked features among the infirmities of poor humanity. For all nervous affections requiring a soothing rather than a stimulating climate, Southern California is preferable to Northern. In those kidney diseases in which it is desirable to make the skin do double duty, the hot, dry climate of the deserts is very advantageous. In the management of phthisical or merely feeble or delicate patients, the mildness of the Southern climate is of exceeding value. Out-of-door life is possible almost every day in the year.

DR. H. S. DOME read an able

REPORT ON MEDICAL LEGISLATION.

Not only should the public be shielded from the malpractice of charlatans, but the profession also should be protected from the intrusion of unqualified practitioners.

DR. R. BEVERLY COLE read the *Report on Gynecology*, and DR. BARKAN the *Report on Otology*.

The Nominating Committee made their report, in accordance with which the following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—IRA E. OATMAN, M.D., of Sacramento.

Vice-Presidents.—DRS. W. S. THORNE, of San José; R. K. REID, of Stockton; W. F. MCNUTT, of San Francisco; R. H. PLUMMER, of San Francisco.

Treasurer.—DR. F. W. HATCH, of Sacramento.

Permanent Secretary.—DR. WALLACE A. BRIGGS, of Sacramento.

Board of Censors.—DRS. GEO. W. DAVIS, C. A. KIRKPATRICK, C. CUSHING, A. G. ANTHONY, G. G. TYRRELL.

DR. ANABEL STUART read a *Report on Diseases of Women and Children.*

DR. J. BRADFORD COX reported two cases of *Knife Wound of the Chest.*

DR. HENRY WORTHINGTON submitted a

CONTRIBUTION TO THE TREATMENT OF PULMONARY BASIC CAVITIES,

in which he considered only uncomplicated basic cavities, the result of tubercular or inflammatory processes. Of some three hundred and sixty cases of pulmonary disease of which he has record, thirty-one were uncomplicated disease of the base, and of these twenty-eight had cavities.

Treatment in most cases consisted in constant use of respirator, internal use of bichloride of mercury and muriate of ammonia, hydrate of chloral externally as a counter-irritant, and a suitable atmosphere at a proper altitude. The mercury may be given in one-thirty-second grain doses, three times daily, as an antiseptic tonic. Its effect is often magical. In extreme cases many times these doses will be tolerated with the happiest result. In seven-grain doses every four hours, or in two-grain doses half hourly, muriate of ammonia stands preëminent among the expectorants. The continuous use of the respirator is a rational as well as admirable method of pulmonary antiseptics. A few drops of oil of eucalyptus on the respirator effectually disinfect the cavities and destroy the fetor of the expired breath. The ethereal tincture of iodine with creasote is more irritating, but very satisfactory.

DR. HENRY GIBBONS read a *Brief History of Medical Law in California.*

A paper on *Etiology and Non-infection of Sewer-gas* was read by DR. WASHINGTON AYER, and one on *Pneumonia* by DR. ALBERT CHASE.

DR. E. N. FOOTE submitted a paper on *Ovarian Dropsy* cured after thirty-four tappings, with theories of cure.

DR. E. H. WOOLSEY read a valuable and interesting paper entitled *Five Cases of Double Synchronous Amputation of Lower Extremities.* He advises operation during shock.

DR. J. GREY JEWELL read a paper on *Alcoholism.*

The attendance and interest of the meetings were well maintained throughout the various sessions, and culminated in the banquet spread at the Baldwin by the profession of San Francisco.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Thirty-first Annual Session, held at Norristown, May 9, 10, and 11, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE Medical Society of Pennsylvania met in annual session, at Norristown, on Wednesday, May 9, at 10 A.M. *The President*, DR. WILLIAM VARIAN, of Titusville, in the Chair. An unusually large number of delegates and permanent members were present.

After prayer, by the Rev. Joseph McCaskey, the Secretary read the list of delegates, and DR. HIRAM CORSON, Chairman of the Committee of Arrangements, delivered an

ADDRESS OF WELCOME,

in which he referred to some of the interesting features of Montgomery County, and alluded to some of the great events of the Revolution which make the vicinity of Norristown historic ground by the footsteps of Washington and those who afterwards suffered with him at Valley Forge.

MEMBERS BY INVITATION.

DR. MARK L. NARDYZ, of Philadelphia, was made a member by invitation.

REPORT OF DELEGATES TO SOCIETIES.

A report was read by the Secretary, presented by the delegates sent to the *American Medical Association* at its meeting at St. Paul, which referred to the appointment of a Committee upon Journalizing the Proceedings of the National Association; spoke approvingly of a resolution offered by Dr. Gihon, that "it will be conducive to justice and the dignity of the profession, if medical expert testimony can be presented to the Courts without the appearance of bias or influence from either side of the case, and simply as a straightforward statement of scientific facts." The Association honored itself and this Society by electing to the presidency the venerable John L. Atlee, of Lancaster. The hospitality and kindness of the citizens of St. Paul were referred to in the highest terms.

Reports from delegates to other societies were called, but none were presented.

COMMUNICATION FROM CHESTER COUNTY SOCIETY.

The *Corresponding Secretary*, DR. JOHN G. LEE, of Philadelphia, read a communication from the Chester County Medical Society, containing a schedule of examination for students commencing the study of medicine.

CONDITION OF LIBRARY.

DR. BENJAMIN LEE called attention to the unsatisfactory provisions now existing for the Library of the Society, and recommended that a committee be appointed, with power to act, to rent suitable accommodations in Philadelphia for the books. On motion, it was laid on the table until the next day.

STATE BOARD OF HEALTH.

By unanimous consent, DR. BENJAMIN LEE, Chairman of the Committee on State Board of Health, presented his report, as follows: The Committee, warned by previous failures, took pains that the bill to be presented to the present Legislature should be as free as possible from all objectionable features. The bill was introduced into both branches of the Legislature, and the Committee held personal interviews with several members of the Senate and House of Representatives. They demonstrated the advantage it would be to the Commonwealth, and did everything in their power to have it passed. The measure was rapidly making friends in both houses, when an amendment was offered proposing to recognize by name and to make it obligatory on the Governor to appoint upon the Board the adherents of an exclusive dogma of medicine. This was met with opposition by the medical members of the Legislature, and the bill, after being subjected to a number of amendments, was finally lost. No previous bill on this subject had received so much attention, or has been so fully discussed. The Committee feel confident that the seed thus sown will eventually bear fruit. The report closed with an appeal.

PUBLICATION COMMITTEE.

DR. WM. B. ATKINSON read the report of the Publication Committee, stating that 1,700 copies of the *Proceedings* of the last year had been printed and distributed to the members and exchanges. The expense was $1,259.86. Forty-two volumes remain on hand. The report was approved and adopted.

The report of the Committee on

SUBJECTS FOR PRELIMINARY MEDICAL EXAMINATIONS

was read by DR. O. H. ALLIS. It recommends the appointment of three examiners by each county society, without whose certificate no member of the society shall receive a student, and a full three years' course of study. The schedule of subjects recommended includes a written statement of the student's course of study, an essay, writing from dictation, spelling, reading, geography — descriptive and physical, political economy, history—ancient and modern, geology, botany, chemistry, natural philosophy, mathematics, arithmetic, algebra, geometry, English, Latin, and Greek.

DR. EDW. JACKSON offered the following resolution:

Resolved, That a committee consisting of one member from each county society be appointed at the same time and in the same manner as the nominating committee, to confer with the committee which has just reported a schedule, and report a plan for the examination of students, under the head of unfinished business, on Friday morning.

After some discussion, he accepted an amendment offered by DR. W. T. BISHOP, of Harrisburg, referring the matter to the nominating committee, and giving each delegation the privilege of substituting another member. In this shape the resolution was adopted.

NOMINATING COMMITTEE.

The delegations were called upon for members of the Nominating Committee with the following result:

Bradford, E. P. Allen; Bucks, Frank Swartzlander; Cambria, W. B. Lohmon; Crawford, Geo. O. Moody; Dauphin, W. T. Bishop; Delaware, I. N. Kerlin; Indiana, Wm. Anderson; Lancaster, J. A. E. Reed; Lycoming, Thomas Lyon; Montour, S. S. Schultz; Northampton, Chas. McIntire, Jr.; Philadelphia, Wm. G. Porter; Snyder, J. F. Kanawell.

NEW YORK CODE.

Under the head of New Business, the following resolutions were adopted unanimously:

Resolved, That the State Medical Society of Pennsylvania reaffirm its approval of, and adhesion to, the Code of Ethics adopted by the American Medical Association.

Resolved, That organized opposition by local societies or by individual members to the Code approved by the Medical Association of the United States, is rebellion against the constituted authorities, and should be so treated.

Resolved, That the Secretary be instructed to forward a copy of these resolutions to the Committee of Arrangements at Cleveland, for presentation to the Association.

MISCELLANEOUS BUSINESS.

An amendment to rules of order offered at the last session, "*Resolved*, That Rule IX. of the Rules of Order be amended so as to allow a suspension of the rules by a two-thirds vote of the members present," was discussed and adopted.

A bill for $41.46 was presented by the Committee on State Board of Health for incidental expenses, and ordered to be paid.

DR. BENJAMIN LEE exhibited two devices for the relief of writer's cramp, one having a ball enclosed in the palm of the hand, and the other consisting of a sort of bracelet, to each of which the pen is to be attached.

AFTERNOON SESSION.

DR. W. M. WELCH, of Philadelphia, read a paper on

THE WEARING OUT OF VACCINE PROTECTION AND THE EFFICACY OF REVACCINATION.

Jenner not only believed in the identity of smallpox and cowpox, but even entertained the fanciful notion that cowpox in the animal was the original or parent form of smallpox in man. According to this view, vaccinia in man was believed to be smallpox in its primitive and mildest form. Hence the protection which resulted from vaccination was regarded as permanent; or, at least, as permanent as that afforded by once undergoing smallpox.

This pleasing, but illusory doctrine was long entertained; but time and greater experience have developed an accumulation of facts which lead to a very different conclusion. It is the author's purpose to show, *first*, that the susceptibility to smallpox, however thoroughly destroyed by vaccination, may subsequently return; and, *secondly*, that revaccination can be depended upon to destroy again this return of susceptibility to the disease.

Among the most valuable statistical data proving the first proposition—valuable, because there is no room to doubt the reality and efficiency of previous vaccination—are those collected in the British army, from 1834 to 1838 inclusive. The regulations of the army required every individual connected therewith to be thoroughly vaccinated, excepting only those who had had smallpox; but revaccination was not then enjoined. The average strength of the army during this period was (including men, women, and children) about 105,000; of this number, 1,025 were attacked by smallpox, and 122 died, giving a death-rate of 11.9 per cent.

The statistics of smallpox hospitals show that a large proportion of the cases of the disease occur among persons vaccinated in early life. During the great epidemic of 1871–77, 2,377 cases were admitted into the Municipal Hospital of Philadelphia, and of that number, 68 per cent. occurred in persons vaccinated in early life. During the recent epidemic—1880–81–82—there were 1,659 admissions, and 54 per cent. of these were post-vaccinal cases. The proportion of such cases is seen to be 14 per cent. less in the late epidemic; the explanation of which is, that revaccination was more extensively employed then, in Philadelphia, than ever before.

Dr. Welch endeavored to show still further, that the deterioration of vaccine protection is progressive; increasing up to a certain period of life with the distance of time from the primary vaccination. To prove this, he submitted the following table, containing a classification of 2,907 cases of post-vaccinal smallpox which have come under his own observation: showing the relative numbers and ages of persons attacked by the disease after vaccination, also the ratio of deaths to the numbers attacked at the various ages.

Under 5 Years of Age.	Cases.	Deaths.	Percentage of deaths.
Good cicatrix,	1	0	.....
Fair "	4	1[1]	.....
Poor "	5	1	.....
Total,	10	2	.....
From 5 to 10 Years of Age.			
Good cicatrix,	11	0	.....
Fair "	9	0	.....
Poor "	26	8	30.73
Total,	46	8	17.39
From 10 to 15 Years of Age.			
Good cicatrix,	45	2	4.44
Fair "	18	2	11.11
Poor "	36	4	11.11
Total,	99	8	8.02
From 15 to 20 years of age,	388	47	12.11
" 20 to 25 "	745	96	12.88
" 25 to 30 "	580	92	15.86
" 30 to 35 "	356	64	17.97
" 35 to 40 "	249	51	20.48
" 40 to 45 "	154	38	24.67
" 45 to 50 "	105	22	20.95
" 50 years and over,	175	63	36
Grand total,	2907	491	16.89

Note.—Doubtless, very many cases classified in the table under the headings of "poor cicatrix" were never successfully vaccinated.

The table, while it certainly shows a very gradual increase in the number of cases of post-vaccinal smallpox during the earlier periods of life, proves that the maximum number occurs at the periods immediately following puberty, thus indicating that at this eventful epoch some change is brought about in the animal economy that lessens or entirely destroys the protective influence previously exerted by vaccination. This may be the same even when the vaccination had been most thorough and complete. Dr. Welch has seen smallpox occur in persons presenting more than twenty typical vaccine marks; and he has known death to occur when as many as twelve such marks were present. The sooner, therefore, the profession and the public fully recognize the necessity of revaccination in all persons at the age of puberty, if not earlier, regardless of the quality or number of their vaccine scars, the sooner shall we succeed in the noble work of preventing smallpox, or of cutting short epidemics of the disease.

If then vaccination of the highest degree of excellence fails to confer permanent protection against smallpox, how much less must be the protection that comes from vaccination of an inferior character—such, for instance, as results from the use of partially deteriorated virus. The deterioration or diminished efficacy of vaccine virus by long humanization is a question which has been variously regarded by different observers—being accepted by some as an axiom, and rejected by others as a mere fancy. For himself, Dr. Welch said he had no hesitation in saying it was his belief that vaccine virus not only loses much of its vigor through a long series of human transmissions, but that it also suffers in the durability of its prophylactic power.

Typical vaccinia, or that type of the disease which should result from the use of animal lymph or lymph of recent humanization, requires for its fullest development and completion not less than twenty-one days, and sometimes a much longer time; while long-humanized virus not unfrequently induces a form of the disease which runs its course in about two weeks. The former is followed by a permanent, well-defined, and characteristic scar; the latter, by a superficial and ill-defined scar.

It is true that vaccinia of short duration will destroy the susceptibility to smallpox. Dr. Welch has had ample proof of this; furthermore, he would say that for vaccination after exposure to the variola contagium, his preference is for humanized virus somewhat remotely removed from the heifer, on account of the more speedy development of the vesicle and the earlier appearance of the areola. But the point he wished to emphasize is, that the protection which results from vaccinia of short duration is not so durable as that which results from vaccinia of a perfectly typical character; or, in other words, the prophylactic power exerted by long-humanized virus is less durable than that exerted by bovine lymph or lymph of recent humanization. To prove this, after what has been said, it is only necessary to show that smallpox is more fatal among persons showing poor or even fair vaccine scars than among those showing good scars. His statistics show the death-rate to be nine per cent. among patients having good cicatrices, sixteen per cent. among those having fair, and twenty-seven per cent. among those having poor cicatrices.

Having shown the necessity for revaccination, it yet remains to say something about its efficacy. Undoubtedly there is a great deal of confusion in the minds of practitioners as to what constitutes successful revaccination. Many believe that unless the vesicle pursues the course of typical vaccinia the disease is spurious and without value. But, certainly, there is no more reason why the disease induced by revaccination should be true and typical than that smallpox after vaccination should be true and typical. As varioloid differs in various degrees of severity from true smallpox, so does vaccinoid differ from true vaccinia.

Some of the most conclusive proofs of the efficacy of revaccination is furnished as the result of experience in various armies. During the Franco-Prussian war, the Prussian army, in which revaccination was carefully and systematically performed, lost by death from smallpox—under circumstances of great exposure to the disease, only 263 men; while the French army, in which revaccination was not enjoined, lost 23,468 men; and the latter army was at no time much more than one-half the size of the former.

During an experience of more than twelve years in hospital work, Dr. Welch has found that only very few

[1] This case, not at all severe, occurred in a very delicate child—a foundling—one year old.

patients have been admitted to the hospital with varioloid who presented evidence of having been successfully revaccinated, and these few have had the disease in so mild a form that death has not occurred in a single instance. No person entering the hospital in any official capacity—as resident physician, steward, matron, nurse, laundress, or other employé—who had taken the precaution to be revaccinated before entering on duty, has suffered from smallpox in any form whatsoever. But, on the other hand, he has seen a few employés, in whom revaccination was for some cause omitted, become infected by the disease.

With such facts as these before us, the conclusion seems inevitable, that if vaccination be efficiently performed in infancy, and revaccination at puberty, if not earlier, we should then begin to realize the truth of Jenner's assertion, viz., *that vaccination is capable of extirpating smallpox from the earth.* But whether vaccination will ever be so universally and wisely employed as to confer on mankind its greatest possible benefits is doubtful.

DR. JAMES TYSON, of Philadelphia, then read the

ADDRESS IN MEDICINE.

(*See page 519.*)

DR. ESKRIDGE, of Philadelphia, endorsed the paper of Dr. Tyson, and stated that he had lived in a malarial region for many years and believed that hæmaturia is increasing in frequency in this country. He also spoke of the pathology of the disorder, and the destruction of the blood-corpuscles by the malarial poison, combined with the tendency to congestion of the internal organs. He believes that malarial disorders are changing their type, and in localities where they were formerly unknown, they are now frequent and virulent. In the treatment he approved of quinine, mineral astringents, and particularly belladonna.

OBSTETRICAL NOTES.

DR. R. L. SIBBETT, of Carlisle, read a communication based principally upon personal experience with 120 cases of child-birth; of this number there was one per cent. of maternal deaths, and eleven per cent. of still-births or death soon after birth. Forceps were used in about six per cent. of the cases. In two cases of placenta prævia, the mothers were saved, one child was dead, and one was asphyxiated but was revived by a hot bath. In one case of breech presentation, the midwife was unable to deliver the head, which remained in the pelvis several hours. He found the child dead; he decapitated it, but still could not deliver the head. Finally, he went to a neighboring blacksmith, who fashioned a sort of a vectis or hook, with which he succeeded in delivering the woman, who is still living. There was a single case of eversion of the uterus from precipitate delivery, while the patient was out of bed.

DR. HUGH HAMILTON, of Harrisburg, then read a paper on

ARTIFICIAL INFANT ALIMENTATION,

in which he advocated the use of mixed healthy cow's milk rendered alkaline by bicarbonate of soda, with the addition of a tablespoonful or two of good cream to every half pint of milk. The food to be heated to a temperature of 131° F., and afterwards sweetened by a strong, freshly prepared syrup of milk-sugar.

DR. R. N. CHASE read a paper on

INSANE ASYLUMS IN SOME OF THEIR RELATIONS TO THE COMMUNITY,

in which he refuted the popular delusion that persons of sound mind are frequently sent to institutions for the insane through sinister motives.

A number of distinguished alientists were cited, whose experience confirmed this statement. He also briefly alluded to the jury system of commitment, which is advocated as a remedy for this alleged wrong. He then considered the relation which insane hospitals bear to the causes of mental diseases, and remarked upon the melancholy fact that the work of hospitals in restoring the insane tends to spread the disease by the mysterious laws of heredity.

DR. PARRISH, of New Jersey, discussed Dr. Chase's paper, by invitation of the Society. He declared himself in accord with the position taken by the author of that paper. With regard to the last meeting of the Association for the Protection of the Insane, and a sensational paper which was read there, he merely wished to state that this paper did not represent the opinions of the Society, and was so palpably full of false statements that the Publication Committee threw it out of the *Transactions*. He believed if Dr. Chase's paper had been read before that Society, it would have been welcomed just as warmly as it was here. He mentioned this to show that the Society referred to did not sympathize with the popular clamor with regard to the commitments of sane persons to insane asylums, and their detention there against their will.

DR. STEWART, of Erie, spoke of the case of the prominent physician, whose case attracted so much attention a few years ago, because it was supposed that he was sane and unjustly deprived of his liberty. On the contrary, the speaker had known him for years, and knew him to be insane when he was sent to Dixon, Ont., ten years ago; he was taken out from the hospital by injudicious friends, although he had not fully recovered, and he is still insane. The stories he tells of the cruelties he underwent, and the horrors of the asylum are pure fiction. He was visited many times during this time when claimed to be unjustly detained, and yet he had not give any intimation of any grounds for complaint as long as he remained in the hospital.

DR. ULRICH, of Chester, said that he regretted that any misunderstanding had arisen with regard to the Society for the Protection of the Insane. The paper referred to had been at once denounced by the members of the Society, and he did not believe that such a paper would be again read before it.

DR. HIRAM CORSON said that he still thought that some reason must exist for the public clamor against insane asylums. He believed that some changes might be made with advantage. He knew of persons kept in the hospital who would be better off at home. There are sane persons in the hospitals often, because patients are not discharged as soon as they get well. Some appear to have no homes, and may remain for years in the hospital. Others are kept in the asylum, because they are more trouble to take care of at home. He referred to a case where a wife, as harmless as a child, has been kept in a hospital by her husband for years, and will probably die there; she would like to be out, and the speaker had tried to get her out, but without success, although she would have a much better chance for recovery outside. He thought that homes or retreats might be provided for this class, where they could be treated without being under the restraints of the asylum, and being depressed by the thoughts of their existence there.

DR. PARRISH said that another cause of the apparent commitment of sane persons to hospitals was the existence of drunkenness, which too often is looked upon as temporary insanity. Physicians do not sufficiently distinguish between beginning insanity and alcoholism. He regarded the law as defective. So long as drunken persons can be committed to an insane asylum, just so long will there be a popular outcry against imprisoning sane individuals. He knew of a man who had been sent thirteen times to an

asylum, and each time entered as insane, and a short time afterwards he was invariably discharged as cured. In this way, the number of cases of insanity is apparently greatly increased. Such cases should be sent to an inebriate asylum, not to an insane hospital.

DR. SCHULTZ, of Danville, thought that some of the popular ideas on the treatment of patients in institutions for the insane arises from the fact that there is a large number of people who, having been in insane hospitals, and discharged, give statements of imaginary injuries and bad treatment to persons they meet, who do not suspect that these hallucinations are a part of the mental disorder, and do not detect the insanity of the patient. He denied that there is any difficulty in getting out of a hospital, for patients can always apply to the Courts; this being the case, no legislation will succeed in quieting public clamor.

DR. CORSON said that it may be easy enough for a man to get out, but it is not so for a woman, if her husband chooses to keep her inside of the hospital, even if a residence outside would facilitate recovery, and he reported a case in point.

DR. DE FOREST WILLARD, of Philadelphia, then presented a paper on

CLUB-FOOT, A FEW SIMPLE MEASURES FOR ITS EARLY RELIEF,

in which he discussed the subject of congenital talipes in reference only to the necessity for the commencement of treatment as soon as the child was born. No delay was necessary, as a simple adhesive strip of rubber plaster would hold the foot in position, but as this became soiled, and would irritate the skin, more permanent measures should be adopted. The indications were to bring the foot into its normal position and retain it there. The first could be best accomplished by the hand, and as nothing was equal to manual pressure, it should be perseveringly employed by the surgeon, and by the mother or nurse. Every contracted tissue should be stretched to the limit of the child's endurance many times each day, and to prevent a recurrence of the deformity, retentive measures should be constantly employed, as even the weight of the clothing would tend to misshape the bones. To secure the foot in its proper position, various methods were demonstrated, including the use of sole leather, felt, binder's board, tin, plaster of Paris, silicate of soda, and elastic tension.

By any of these means no one need permit a case of talipes to increase for want of retention dressings, while waiting for the child "to be old enough for operation." By the persistent use of the measures designated, it will frequently be found that tenotomy is unnecessary, and in the severer cases where section of the tendon is required, the operation will prove a far greater success on account of the preliminary treatment, since relapses will be less frequent.

Should the success, with the plan advised, warrant a continuance of the efforts, the same principles can be carried out by the simple plan adopted by the author, of attaching an arm to the stirrup used in the steel uprights of an ordinary club-foot shoe, at the end of which arm is an eye through which plays a catgut cord, fastened opposite the anterior heads of the metatarsal bones (either externally or internally, according as the case be one of varus or valgus), and to which cord is attached elastic webbing running up to be fastened to a button at the top of the upright. An inexpansive joint, which permits motion in every direction as readily as a ball-and-socket joint, is formed opposite the medio-tarsal articulation by simply paring down the sole for a half inch in front of the stirrup to the thickness of a piece of writing paper. If the child is not walking, and no dirt or water will enter, the anterior part of the shoe can be made separate from the heel portion, the connection at the sole being only by means of a strip of soft upper leather. Such a shoe fulfils perfectly and simply the indications required, namely, the rectification of the deformity at the astragalo-scaphoid and calcaneo-cuboid articulations, while, at the same time, the plantar fascia and the contracted gastrocnemius and soleus are stretched, if the case be one of equino-varus. Should the contractions fail to yield, tenotomy or other operative measures must be instituted, but the present discussion is purposely limited only to simple, ready, mechanical means of cure.

EVENING SESSION.

The Association met at 8 P. M. to hear the

ANNUAL ADDRESS OF THE PRESIDENT,

delivered by DR. WILLIAM VARIAN, of Titusville, who said—

Gentlemen: Thirty-five years ago there met, in the city of Lancaster, a small and earnest body of medical men, who organized the Medical Society of the State of Pennsylvania, and announced as their object "The advancement of medical knowledge, the elevation of professional character, the protection of the professional interests of its members, the extension of the bounds of medical science, and the promotion of all measures adapted to the relief of suffering, the improvement of the health, and the protection of the lives of the community." More than a generation of human beings has accomplished its earthly pilgrimage since that meeting was held; yet it is still our privilege to see in the audience here assembled more than one of the original founders of this Society, who in the year 1848 were present at its organization. In contrast with that period, and of the few early members, he pointed to the eighteen hundred names now enrolled upon the list of members, and to the increase in importance and influence of this Society, and its great work already performed in unifying the profession, and in influencing efficient legislation in behalf of State hygiene. In referring to the great work yet to be done, he very earnestly called attention to the need of a State board of health, strengthened and supported by local boards in every city, town, and borough; and in spite of discouragements, he urged continuing their efforts upon the Legislature, until the necessary authority is conferred. He then spoke of the hygienic problem of the disposal of the dead, and advocated cremation, as a measure both of public hygiene and æsthetic fitness. Calling attention to the need of more enlightened and humane treatment of the inebriate, whose organs and tissues are in a state of disease due to chronic alcoholism, he invited attention to the great improvements that have recently been made in the treatment of the insane and feeble-minded from other causes than alcohol, and declared his conviction that some such steps should be taken on behalf of the equally unfortunate and irresponsible victims of alcohol, who now are too often treated as felons, and thrust into the workhouse or jail, then discharged with enfeebled mind and body to encounter temptation, without having obtained any physical or mental strength to resist their depraved instincts. The frequent repetition of this course soon produces a real criminal, or else ends in a pauper's grave or an insane hospital. The elegant asylum where the rich inebriate may go after his debauch has the same fault, the patient is too often allowed to go out before he has physical strength to reform.

The topic of vaccination was then taken up, and the relative merits of humanized and bovine lymph compared; having tried the bovine virus for ten years, he had gone back to the humanized, as being more cer-

tain, reliable, and efficient than the bovine, which often produced phagedenic ulceration. He said, "an experience of nearly thirty years' use of humanized virus has shown me that it possessed great power against variola, together with certainity of action and freedom from any such effects as above described. Less than ten years' use of animal virus has led me to believe that it is uncertain in its action, that its protective power is not so lasting, and that, at times, it was not free from a liability to produce disastrous effects." Its protective power seems to be in many cases much less than the former, and in the inflammatory cases there is a grave doubt if it confers any protection at all. There is great need of State supervision over the sources of vaccinia.

In connection with medical education, he asked that the establishment of a chair of State medicine and hygiene be urged upon our medical schools, attendance being made obligatory, and that the students be required to pass an examination upon the lectures previous to graduation.

The dilatory appearance of the *Transactions* of the Society was mentioned, and as a means of remedying this fault which had given rise to just grounds of complaint, he suggested reducing the Publication Committee to one member, who should be made responsible for the early appearance of the work; or the offering of the *Transactions* to some weekly medical journal for early publication, in place of issuing the annual volume.

The action of the New York State Medical Society in rejecting the Code of Ethics, and renouncing the authority of the American Medical Association, was condemned in no measured terms, and denounced as unnecessary, unjustifiable, and revolutionary.

The orator closed his address by an appeal to the non-medical portion of his audience to encourage higher medical education, to sustain efforts to obtain legislation for sanitary purposes, and to advance State medicine, and recommended the endowment of chairs in established medical schools in preference to starting new enterprises, thus enlarging the usefulness and lessening the expense of a generous medical education.

RECEPTION AND BANQUET.

The State Medical Society was honored by a reception and banquet this evening, given by the Montgomery County Medical Society. The entertainment was largely attended by the members and their ladies.

THURSDAY, MAY 10TH. SECOND DAY.

MORNING SESSION.

After prayer by the Kev. H. M. Kieffer, the Nominating Committee was announced.

DR. A. CRAIG, of Columbia, then read the

ADDRESS IN SURGERY.

DR. E. O. BARDWELL, of Emporium, read a practical paper on

SCARLET FEVER AND ITS TREATMENT,

based upon a series of 176 cases under his care. He found that, as a rule, coincidently with desquamation albumen, red blood-corpuscles, tube casts, and epithelial cells appeared in the urine. He regards the renal trouble as being not a sequela, but one of the essential phenomena of the disease. For this condition of the kidneys, hydragogue cathartics (compound jalap powder particularly), and infusion of digitalis with potassium acetate, are considered the most useful remedies. Tincture of the chloride of iron, is highly recommended for the throat, and for its effect upon the kidneys; for headache, potassium bromide is recommended in preference to morphia, which should be avoided on account of its influence in decreasing the urinary secretion. Quinine as an antipyretic is worse than useless, in comparison with the tepid bath or pack, the effects of which are much more lasting.

In cases of uræmic convulsions, the hot bath frequently repeated, stimulating enemata, and compound jalap powder, have proved successful in restoring the patient.

Of the 176 cases, only five died; three of these were moribund when first seen, the other two died from the effects of diphtheritic complication.

DR. E. A. WOOD, of Pittsburg, then presented a paper on

A DEFORMITY WHICH SOMETIMES FOLLOWS DISLOCATION OF THE FOOT OUTWARDS AT THE ANKLE-JOINT.

After a severe injury, as a blow or a fall, by which the foot is dislocated outward, and by which the distal end of the tibia is contused, split, or impacted, but in which the luxation is the only condition manifest, it sometimes happens that the ankle is deformed by enlargement of the distal end of the tibia, by increased malleolar space, by turning of the foot outward, as in *talipes valgus*, and by the foot presenting outside the axial line of the leg.

Injury of the end of the tibia is likely to be followed by inflammation and enlargement, and the degree of each will be proportionate to the severity of the force which caused the same. Enlargement must widen the malleolar space—space which the astragalus cannot fill. In this case, the deformity is obvious. But there are other elements which add to the deformity. In the case before us the internal lateral ligaments are completely severed, while the external lateral are not. When the intermalleolar space is widened, the intact ligaments which bind the foot to the fractured lower end of the fibula will keep the foot in contact with the latter bone, while the internal malleolus will project inwards. This distance between the internal surface of the astragalus and the internal malleolus will retard or make impossible the repair of the internal lateral ligaments.

It will be seen that the deformity may not be apparent when the dressings are removed, say at the end of two months, but when the patient attempts to walk on the injured member he finds it weak and tender. When he persists in bearing his weight thereon, he will soon begin to notice that the foot is not right, and the surgeon will then see that that member is turned outward, is outside the leg axis, and that the internal malleolus forms a very prominent tumor, almost touching the floor when weight is borne on the unsound foot.

If the surgeon is observant, he will now see why the deformity exists; the intermalleolar space is abnormally widened, making repair of the internal lateral ligaments impossible or insufficient.

The only way to arrest the trouble and make the deformity minimum, is to keep the foot in suitable dressings for a long time, and that time may be a year or years. At the shortest and best, it will be a long time.

DR. WILLIAM PEPPER, of Philadelphia, then read a paper entitled a

CONTRIBUTION TO THE CLINICAL STUDY OF TYPHLITIS AND PERITYPHLITIS.

After alluding briefly to the usual favorable course of ordinary cases of this affection, he dwelt upon the extreme importance of pursuing treatment embracing absolute rest and a carefully restricted diet, until a complete cure was effected, so as to avoid the very strong tendency to relapse. Allusion was made to the ulcerative and perforating forms, and he dwelt upon the importance of the early recognition of the tendency

to abscess. Exploratory puncture should be made, followed by operation for evacuation if abscess be detected.

Cases were quoted illustrating some of the difficulties of diagnosis and the advantage of operation. Especial stress was laid upon the strong tendency of such cases of typhlitis to recur, and finally, unless treated with great care, to pass into a chronic form. Several illustrative cases were given bearing on this point, which further showed that even where very frequent relapses had occurred, a complete and permanent cure might be obtainable.

Dr. S. W. Gross, of Philadelphia, read a paper on

THE THOROUGH REMOVAL OF CARCINOMA OF THE BREAST,

in which he advocated the amputation of the entire breast with its superjacent skin and fat, no matter how small the growth may be or how sound the skin may appear, along with the removal of the fascia of the pectoral muscle, and opening the axilla, with a view to cleaning it out if the glands are found to be invaded by the disease. This mode of operating is indicated because the remains of the breast, the fat, skin, pectoral fascia, and axillary glands are the seats of recurrence, or rather of the continuous growth of portions of diseased structures which are left behind in the operations as usually performed. For these reasons, the operation which he suggests is alone adequate to effect riddance of the tissues in which reproduction takes place.

Dr. Gross has operated in the manner indicated in 20 cases, of which only one died. Excluding one case, in which all diseased structures could not be removed, and 3 in which the history ceased with the recovery of the patient, he gave a synopsis of the remaining 16. Of these 9, or 56.25 per cent., were failures, one having died, one having been incomplete, and 7 having recurred within a year; and 7, or 43.75 per cent., were successes, the patients having remained free from recurrence for periods varying from eleven to fifty-six months, or twenty-seven months and a half on an average. Three of these living cases were presented to the Society, of which one was free from reproduction for sixteen months and a half after operation, one for three years and eight months, and one for four years and eight months. In the first and third cases the axilla was cleaned out, while in the second it was explored with the finger, but as it was free from disease, its contents were not disturbed. In all of these patients the cicatrices were soft, pliable, and freely movable on the pectoral muscle.

THE TREATMENT OF PURULENT PLEURAL EFFUSIONS

was considered in a paper by James C. Wilson, M.D., of Philadelphia. He said that, with few exceptions, pleural effusions are not primarily purulent, but serous; they become purulent by degrees, resorption not taking place, and the inflammatory process continuing. From a clinical point of view, the distinction between fibrinoserous and purulent exudations is of the highest importance, as the former are capable of resorption; the latter, as a rule, are not. Physical signs alone will not determine the character of the effusion; but the coexistence of great pallor, emaciation, irritative fever and sweating, or diarrhœa, makes the presumption of the existence of pus very strong. In case of doubt, a hypodermic syringe will enable us to make a diagnosis by an exploratory puncture and aspiration. The treatment of purulent collections in the pleura is affected by the age of the patient. In a child, repeated aspiration is often followed by complete cure. This result will not follow in adults; it is in vain to look for cure in such cases by this means. In order to cure, it becomes necessary to establish a thoracic fistula with as little delay as possible, the pyogenic surface of the pleura being frequently washed with antiseptic injections. The fistula is to be kept open for free drainage until the patient is cured. The question of whether the empyema be primary or secondary, does not affect the treatment of the pleural pus collection. The point of election is in the sixth or seventh interspace in the posterior axillary line. The preliminary aspiration of part of the fluid is recommended a few days before the operation for permanent drainage. Threatening collapse may be relieved by cardiac stimulants, and a hypodermic injection of morphia. The administration of salts of ammonia after operation, and the exercise of due care in washing out the pleural cavity, are advised, in order to prevent heart-clot.

The main steps of the operation and after-treatment are outlined as follows:

The Preliminary Aspiration.—The puncture by means of short trocar (not exceeding two inches in length), the canula being retained only until the pus ceases to flow, when a soft rubber (Nélaton or Jacques) catheter is slipped through the canula, and the latter withdrawn. Catheters are preferable to sections of drainage-tubes, by reason of the ease with which they can be reintroduced into the sinus by means of a probe. It is occasionally necessary to change the catheter or to remove it to clean it.

Washing out the Cavity.—This is done by a ball-syringe and rubber tubing, and is to be repeated once or twice a day. The temperature of the solution should be 102.5°, and very slight force used; about one-fourth the quantity of pus removed is the right quantity for each injection, which is to be repeated until the fluid comes away clear, or slightly turbid. The solution preferred is mercuric bichloride ($\frac{1}{5000}$) as an antiseptic and disinfectant. This treatment is to be continued until the discharge is serous and reduced to two fluid-drachms daily; the tube may then be withdrawn and the sinus allowed to close. The existence of a spontaneous opening in the chest-wall, does not prove a contra-indication to this precedure; it is generally badly located, tortuous, and inefficient; bronchial fistulæ also do not modify the treatment. The administration of ether is not advisable in performing the operation on account of existing dyspnœa; the adoption of local anæsthesia by the application of ice, will generally prove sufficient.

Dr. Chas. K. Mills read a paper entitled

THE MEDICAL SERVICE OF INSANE HOSPITALS,

in which he discussed the necessity of the individual investigation of patients in such hospitals, the importance of a larger resident staff, the advisability of having a competent consulting board, and a pathologist and microscopist, and similar matters. Some of the suggestions and provisions reported by Governor Hoyt's commission to examine into the present system for the care of the insane in the State, were commented upon, some being advocated, others criticised.

(To be concluded.)

NEW YORK SURGICAL SOCIETY.

Stated Meeting, April 10, 1883.

The President, T. M. Markoe, M.D., in the Chair.

HYGROMA OF THE TONGUE.

(Concluded from page 502.)

Dr. Gerster presented a specimen of congenital hygroma of the base of the tongue, removed from a girl thirteen or fourteen years of age. This cystic swelling was noticed quite early in life. The child

was presented to him by Dr. F. Serr. He found a tumor, of the size of a rather large English walnut, occupying the most posterior portion on the left side of the tongue, extending about two-thirds the length of the tongue forward, and reaching posteriorly to the anterior pillar of the fauces. By a puncture and examination of the contents, he diagnosed hygroma. Finding that the empty sac had rather thick walls, and recollecting that he had had an unsatisfactory experience in treating these tumors by any of the methods commonly employed, he decided to lose no time, but to attack the growth and remove it entirely. He first ligated the lingual artery; he then held the mouth open by the use of Whitehead's speculum; a fillet was thrown through the base of the tongue, and with this the organ was pulled well forward. The tumor was then exposed by an incision carried along the edge of the tongue, and the sac excised by means of the forceps and a pair of scissors. The hemorrhage was so very slight that the excision could be performed rapidly. The cavity was mopped out with a five per cent. solution of carbolic acid, and the edges of the wound were stitched together with very fine silk. He carried the incision along the edge of the tongue purposely, in order to bring it into the portion of the oral cavity where the dressing could be retained without difficulty. A piece of gauze, powdered with iodoform, was placed between the tongue and gums opposite the line of incision, and it was retained in that situation for thirty-six hours. When it was cast out, the wound was found without irritation, and united. Likewise did the deligation wound heal by first intention. The subsequent progress of the case was very favorable, and the child was dismissed from the hospital cured on the fifth day. He thought that complete extirpation of these growths was the most advisable method of treatment, especially for dermoid cysts which occasionally grow in this locality.

URETHRAL CALCULUS.

The PRESIDENT presented a specimen of urethral calculus together with a fragment of a flexible catheter taken from a man sixty-nine years of age, who had suffered for thirty years with vesical symptoms, which during the past ten or fifteen years had been supposed to be due to the presence of a calculus somewhere in the urinary passages. Shortly before the patient came under Dr. Markoe's observation he presented himself to a physician residing outside of the city, complaining of symptoms of stone of the bladder, such as irritation, passage of blood, and stoppage of the stream, and the doctor had detected a stone in the course of the urethra. He then passed his instrument into the bladder, and, as he thought, detected stone there. The case was interesting because it illustrated the uncertainty of the vesical exploration, as would be subsequently seen, when a stone exists in the urethra. The physician stated that he could feel distinctly a stone on either side as he turned the point of the instrument within the bladder. Further manipulations were resorted to for the purpose of removing the stone in the urethra, which was situated just at the peno-scrotal junction. The doctor tried in various ways to get rid of it, but did not succeed; he then hit upon the expedient of taking an elastic bougie, cutting a piece out of one side, and then passing it beyond the stone, hoping that the opening in the side would allow the edge of the stone to so engage in it so that he could pull it out. The idea was correct mechanically, and it caught the stone, but in trying to extract the extremity of the catheter was pulled off and left posterior to the calculus. In that condition the patient presented himself at the New York Hospital. Dr. Markoe found the stone in the urethra, but was not able to form a definite opinion with regard to the existence of a stone in the bladder; nor could he ascertain the position of the fragment of catheter. He therefore proceeded as if it might be possible that a stone existed in the bladder, also thinking that it was quite probable that the end of the catheter had entered the bladder. He made an incision as for the median section in lithotomy, and introduced the finger into the bladder for the purpose of exploration. At this point, it occurred to him to avail himself of the opportunity to test the suggestion made by Sir Henry Thompson, that the inner surface of the bladder could be explored with the greatest facility by the finger for the detection of calculi, tumors, etc., and he therefore instructed himself with reference to this point, and found that he was able with the greatest ease to ascertain exactly any irregularity or any roughness upon the inner surface of that viscus. He found nothing in the bladder; neither stone nor piece of catheter. The inference, therefore, was that the catheter was anterior to the opening in the urethra, which was made in the membranous portion. He therefore extended the incision forward slightly, passed the forceps forward, and first seized the little piece of catheter, and then passing the instrument a little further on, came upon the stone, seized it and removed it. No bad symptoms followed the operation, and the patient was discharged from the hospital at the end of two weeks.

WOUND OF THE INTERNAL JUGULAR VEIN; LIGATION; EXCISION; RECOVERY.

The PRESIDENT also presented a glandular tumor which merely served as a text for the recital of the history of the case in which an operation was performed for its removal. The case was one of lymphoma of moderate size, occurring at about the middle of the left side of the neck, in the chain of lymphatic glands behind the sterno-mastoid muscle. He made his incision so as to reach the tumor behind the sterno-mastoid, and, partly cutting and partly enucleating, without much difficulty reached the deeper portion of the tumor; but when this point was reached, it was found that the growth projected forward and beneath the sterno-mastoid muscle, and he was obliged to draw the entire mass backwards and outwards in order to effect its removal. In so doing, it became very difficult to be certain as to exactly what he saw and what was divided in separating the attachments of the base of the growth. When the tumor was nearly separated, he was suddenly shocked by the occurrence of a hemorrhage which was something terriffic. It was evidently venous blood, and was pouring out in a stream as large as his little finger from the bottom of the wound. Instantly, he plugged the wound with sponges, and then the difficulty was to get at the bleeding point, which was evidently either the jugular vein, or some other vein of large size. For one moment he heard a hissing sound, but he was not certain whether it was actually due to the entrance of air into the vein or not. After a little time, constant and careful pressure upon the bleeding point being continued, he carefully and slowly withdrew the sponge, constant pressure also being maintained both above and below, and was able, after several trials, during which much blood was lost, with the forceps to catch first the anterior source of the hemorrhage, and passed a ligature about it. Bleeding from this point was arrested permanently and perfectly. Then the posterior and deepest portion of the wound was dealt with in the same way; and he finally caught a large portion of tissue, including the bleeding point, threw a ligature about it, and the hemorrhage ceased. When this had been done, he found that the point from which the hemorrhage came was just above the bifurcation of the common carotid artery, and the bleeding

point was evidently from where the lingual and superior thyroid veins unite and empty into the jugular veins, and he tied these vessels. The other ligature was found to be on the side of the internal jugular vein; it was tied firmly; but he felt unwilling, and so he had always felt, to leave a lateral ligature on the jugular vein. He therefore dissected the parts carefully, exposed perfectly and clearly the vessel, put a ligature around it above and below, and cut off a piece between, partly to release the tension, and partly because he wished to see the lumen of the vessel, in order to be sure of what had been done. The points of the severed vein were now at least two inches distant from each other. The wound was left open to heal by granulation. The progress of the case was most favorable, and the patient is now perfectly well, no unfavorable symptom having developed, nor local hemorrhage having occurred.

Dr. S. W. Gross, who has collected the largest number of cases of ligation of veins, has recorded fatal results in twenty-two out of one hundred cases, the fatal results being largely due to phlebitis and septicæmia. Of these twenty-two cases, in five the patient died of secondary hemorrhage, and it was a singular fact that in every one of these five cases the ligature has been applied to the side of the vessel. No death had occurred from secondary hemorrhage in any case included in his tables, from ligature of the vein in continuity or at its cut extremity. Dr. Markoe believed that the proper plan to pursue was to throw a ligature completely around the vessel, and to leave the wound open to heal by granulation.

FRACTURE OF THE BRIDGE OF THE NOSE.

DR. POST was consulted two weeks ago by a young lady from Michigan, who had a deformity of the nose caused by fracture of the bridge. The nose was extremely flattened. He made an incision on each side, opposite the sutures between the nasal bones and the superior maxilla, with the chisel separated the bridge, and then introducing a firm director, brought them up into place as nearly as possible. The wound was progressing favorably, and there was a marked improvement in the deformity, although it had not been entirely corrected.

DR. WEIR remarked that he had found it desirable in a number of cases to fracture the central portion first from within, and then to separate the nasal bones from the maxilla by the chisel, when the fragments could be readily put in proper position, and easily retained there.

NEWS ITEMS.

CINCINNATI.

(From our Special Correspondent.)

A CASE OF NEPHRECTOMY.—DR. C. D. PALMER, of Cincinnati, reported at the last meeting of the Academy of Medicine, a case of nephrectomy in a young lady, æt. 19, of German descent, who had been in poor health for two years and more, suffering, it was supposed, with some ill-defined uterine disease, chronic cystitis and albuminuria. When his attention was asked to the case, she was emaciating rapidly, had a red, glazed tongue, complete loss of appetite, occasional vomiting, and diarrhœa, and complained of frequent and very painful urination. His attention was especially directed to the urine, which was seemingly natural in quantity, but very thick and milky. An examination of it showed mucus, much pus, and albumen (one and half per cent.). The bladder was very tender to touch per vaginam, its walls thickened, and its capacity diminished to ℥ij. Even the introduction of the smallest and softest gum catheter gave pain.

A careful regulation of the diet, and medication, together with the washing out of the bladder with warm water, medicated with salt, boracic acid, morphia, and atropia, only temporarily relieved the patient. A few weeks from his first visit, the patient was seized with chills, followed with high fever and profuse sweating. These chills were repeated twice subsequently, at irregular intervals. Soon following the first, a previously ill-defined pain in the back became very severe, and there was gradually an increasing tenderness and fulness, manifest just anterior to the right lumbar region, so that in some ten days, it presented a defined outline, and a certain degree of doughiness; on several occasions during these ten day, the urine, which for months had been very turbid and evidently purulent, became nearly clear, probably owing to an obstruction within the right ureter.

It was evident that the patient was rapidly loosing ground, and that medical treatment could be of no avail. With a diagnosis of pyo-nephrosis, and with a proposal to institute surgical relief, Dr. Ransohoff saw the patient with Dr. Palmer. An aspirator needle confirmed the existence of pus, and the day following, the patient being under the influence of the a. c. e. mixture, Dr. Palmer, assisted by Dr. Ransohoff, commenced the operation by an incision over the most dependent portion of the enlarged kidney, which was a point about midway between the linea alba and the lumbar region proper, to the right of the rectus muscle. The distended kidney having been reached through the peritoneum, was first tapped with a small trocar, and only a small quantity (1–2 oz.) of pus withdrawn. The incision and point of opening of the kidney were made in this locality, because it seemed highly probable, from the conduct of the enlargement and the nature of the symptoms, that nephrotomy or opening into the kidney, and draining it by a tube, and stitching the wall of the organ to the abdominal walls, might answer every purpose, and be attended with less danger than extirpation of the organ.

But this course proving unavailing, the peritoneum from the line of incision, was stripped off the lateral abdominal walls, exposing the surface of the kidney, which was then enucleated from its bed, ligated at the hilus of the organ with a stout ligature, and cut off. A free opening was then made through the posterior lateral abdominal wall into the cavity remaining for the purpose of drainage, the ligature drawn through, the sac thoroughly cleansed out with hot water, and the abdominal walls closed and dressed much after the manner for ovariotomy.

The patient lived three and half days, and died of peritonitis.

No post-mortem was allowed.

The operation was undertaken with the patient in a most critical condition, and was almost a forlorn hope. It was done because it was the only remaining thing to do.

The kidney removed was greatly enlarged, weighing some 14 oz. Its walls, especially the anterior, much thinned, its pelvis dilated. Numerous sacs, the seat of pus accumulations, were distributed throughout.

The left kidney, in all probability, was healthy. At least, there was no evidence prior or subsequent to the operation, which indicated any disease on that side. It is much to be regretted that a post-mortem could not have been obtained to settle this point, as well as the amount of disease having existed in the bladder.

This is the first case of nephrectomy in Cincinnati, or the State.

NEW ORLEANS.

(From our Special Correspondent.)

THE mortality from smallpox has again become very large. For the week ending April 28th, there were 45 deaths; 17 white, and 28 colored.

MONTREAL.

(From our Special Correspondent.)

CHANGES IN MCGILL MEDICAL FACULTY.—Professor Wright, in whose class there were disturbances during the past session, has resigned. His successor will probably be Dr. James Stewart, of Brucefield, Ont. Dr. McCallum, the Professor of Midwifery and Diseases of Women, has also resigned. He will be succeeded by Dr. A. A. Browne, his assistant, as Professor of Midwifery, and by Dr. Wm. Gardner as Professor of Gynecology.

Dr. Wilkins, of Bishops College, succeeds Dr. Gardner in the chair of jurisprudence, and Dr. R. L. MacDonnell takes the lectureship on hygiene.

BERLIN.

(From our Special Correspondent.)

VEREIN FÜR INNERE MEDICIN.—Medicine has been recently aroused from a long slumber, Professor Leyden acting the prince in the fairy tale. Finding internal medicine more and more overpowered and nearly suffocated by the all-absorbing interest for operative procedures, surgery becoming rather triumphant after the wonderful successes gained by the Listerian treatment, he ventured to separate himself, with Frerichs, Fraentzel, and their followers, from the great general Berlin Medical Society, existing since 1860. This secession took place in 1881, when the medical society was still under the presidency of Langenbeck,[1] who always strongly upheld the principles of the unity of all medical disciples as represented by a great general association. But notwithstanding that this influential leader of the profession published an energetic Philippic against what seemed to him an act of apostasy, the unexpected success of the new "Verein für innere Medicin" has clearly proved its right to existence. To-day the number of its members amounts to upwards of fifty, most of them being also in the mother association. Persevering in his task, Prof. Leyden organized among the teachers of clinical medicine and medical practitioners of Germany a congress which is periodically to be held in the splendid watering-place of Wiesbaden. The first spring meeting held last year was very well attended. Frerichs delivered the opening address. The discussions on Bright's disease, on antipyretic treatment, on styptic medicaments, etc., are already published in the *Transactions*. The second session will be held in the beginning of May.

THE ANNUAL MEETING OF THE GERMAN SURGICAL SOCIETY.—Meanwhile, we have had the pleasure of seeing at Berlin the twelfth annual meeting of the German Society for Surgery last week—B. v. Langenbeck in the chair. Although for the first time leaning on a walking-stick, the Nestor of German surgery presided in his old manner, and seemed as fresh, courteous, and benevolent as ever. It is nearly impossible to give a short abstract of the rich contents of the transactions. There were long debates on operation for goitre, on gastro-enterotomy, on bismuth as an antiseptic. Dr. Hagedorn (Magdeburg) recommended the common bog-moss as a powerful absorbent, excelling by its cheapness, and adapted to displace the more expensive antiseptics, at least in the outer layers of permanent antiseptic dressings. Dr. Fehleisen went so far as to recommend his above-mentioned cultures of the erysipelas micrococci for inoculation in cases of inoperable tumors, or lupus, or chronic inflammatory deposits, arguing that the micrococci, kept pure through a long series of generations, would always produce simple erysipelas, free from septicæmia, or even phlegmonous suppuration, the danger of life thus being reduced to a minimum.

Of single cases brought before the Congress, there is to be mentioned a successful ligature of the common iliac artery, performed by Dr. Kümmel, the assistant of Schede, in Hamburg. Professor Bergmann introduced a patient suffering from aneurism of the innominate, which had been very much diminished in size by the contemporaneous ligature of the right carotid and subclavian, according to the method of Brasdor and Wardrop. Professor Schönborn, of Königsberg, brought forth a very interesting specimen of a kidney-shaped, brownish tumor, wholly consisting of a compact mass of hair. By laparotomy, it was taken out of the stomach of a hysterical young lady, who, for some years, had indulged in biting off the ends of her long tufts, which procedure, according to her opinion, would give her a fine, clear voice. A diagnosis in the somewhat scoliotic patient proved impossible before the operation, the tumor being so movable that all observers inclined to take it for a dislocated kidney. There are seven similar cases mentioned in literature, all with the same etiology—six of them in females. All the patients died, since no diagnosis and no operation were made. Many other papers were read before the Congress. Most of them will be published as usual in Langenbeck's *Archiv*.

[1] Now followed by Virchow.

PREPARATIONS FOR THE YELLOW FEVER SEASON.—At the meeting of the Executive Committee of the National Board of Health, held on the 30th inst., the refuge stations at Norfolk, Va., Sapelo Sound, Ga., and Ship Island, Miss., were ordered to be opened as soon as the necessary details could be arranged. The Inspection Service in New Orleans and on the Mississippi River was also directed to be organized for immediate work. It is expected that by May 15th the preparations will be completed and the stations in condition to provide for the detention and disinfection of suspected vessels, and for the reception and treatment of such vessels as have yellow fever on board. At most of the Southern ports the quarantine laws became in force May 1st.

THE AMERICAN MEDICAL ASSOCIATION.—The next annual meeting of the American Medical Association will be held in Cleveland, June 5–8, inclusive. All railroads west of Pittsburg, Salamanca, and Buffalo, east of Chicago, and south of Cleveland, will carry delegates, and members of their families, to Cleveland at one full fare, and return them on certificate signed by the Chairman of the Committee of Arrangements (certifying that they have been in attendance at the meeting of the Association), at one cent per mile. The trunk lines east of Buffalo, Salamanca, and Pittsburg, and lines west of Chicago, have refused to make any reduction. The rates at the hotels range from $3 to $2 per diem.

THE IOWA STATE MEDICAL SOCIETY will meet at Council Bluffs, and the West Virginia Medical Society at Trapton, on Wednesday, the 16th inst.

THE BOARD OF EXAMINERS OF NORTH CAROLINA will meet in Tarborough on May 14th.

The Missouri State Medical Association will hold its annual meeting in Jefferson City, Mo., on May 15th, 16th, and 17th.

The North Carolina State Medical Society will hold its thirtieth annual meeting in Tarborough on May 15, 1883.

The North Carolina Board of Health will meet in a joint session with the State Medical Society on May 16th.

Women's Medical College of Philadelphia.—Dr. William W. Keen has been elected Professor of Surgery in this institution.

The New York State Board of Health has elected Dr. E. M. Moore, of Rochester, President, and Dr. Elisha Harris, Secretary. The President reappointed all the committees of last year.

Philadelphia Polyclinic.—It is announced that the Philadelphia Polyclinic and College for Graduates in Medicine receives neither *free* pupils nor medical *students* in its classes, which are designed for graduates only. The various departments have now a membership of twenty-six. In some branches, the classes will accept no more members, except by special arrangement for extra hours.

The Code Controversy.—Dr. Jacobi, of New York, in behalf of the advocates of the New Code, has just issued an address in German to the German physicians.

"A No-Code Man" writes to the *N. Y. Tribune* that "the 'New-Coders' would do well to be a little consistent at this particular time, and as the New Code prohibits interviews and other newspaper communications on medical matters, it would not be improper for them to follow its precepts and keep out of the newspapers."

The *N. Y. Tribune*, which apparently enjoys the confidence of the advocates of the New Code, gives the following *résumé* of the present condition of the controversy in New York:

"In the matter of securing signatures to the pledges for and against the re-enactment of the old Code of Ethics of the American Medical Association, the conservative party among the physicians in the city are still considerably in advance of the liberals. The advantage which they secured by early organization and an aggressive campaign at the outset, they continue to maintain. Even their opponents are compelled to admit the excellence of their leadership, and the perfection of their discipline, while they condemn some of the methods employed by them in their effort to regain the territory lost in the County and State societies last year. The criticism of methods, however, is mutual, the conservatives retorting to the charges of secrecy which the liberals make so frequently, that they are not only acting in harmony with the traditional customs of the profession, but that the New Code itself is the achievement of an organization that took them by surprise last year. They say that the delegation which went to the State Society from the County Society was a pledged body, and that they were forced into an organization by the fact that they were helpless in the hands of the greater number and superior parliamentary skill brought to bear against them by their opponents. The latter were active, first, because they were the aggressors, and now they were at the disadvantage of being obliged to defend territory which the conservatives say was won unfairly.

"The Academy of Medicine fight does not seem so much of a mistake to the conservatives as it seems to the liberals. They contend that the resolutions introduced were strictly within the letter and spirit of the organic law of the Academy, the National Code of Ethics being part of its by-laws, and that it was entirely proper to instruct the Committee on Admissions to ask every applicant for fellowship whether he could sign the by-laws, and reject him if he was opposed to them. To this the liberals answer that a New-Code man has a perfect right to become a fellow of the Academy, and that he can conscientiously sign the by-laws without losing his right to disagree with them and work for their repeal within the Academy. The case, they say, is analogous to that of law-abiding abolitionists during the existence of the slave laws. They were bound not to violate them, yet they had the right to go to Congress and labor for their repeal."

A Statement from Dr. Austin Flint, Jr.—In a communication to the *New York Medical Journal* (May 5, 1883), Dr. Austin Flint, Jr., makes the following statements of the causes which led to the presentation of the resolutions which were passed at the late meeting of the New York Academy of Medicine:

"The fact that the president and first vice-president of the Academy, as well as other officers, actively and publicly advocate the State code, which is opposed to the by-laws of the Academy, excites alarm on the part of many Fellows of the Academy, and a fear that the standing of the Academy may, by the attitude of its prominent officers, be gravely compromised.

"Animated by this feeling, a number of Fellows of the Academy, who are in favor of its by-laws as they now exist, and who include four of the five living ex-presidents, prepared a set of resolutions, reaffirming the ethical portion of the by-laws, and I was selected to present these resolutions to the Academy at a regular stated meeting. We also notified those who were known to be in favor of the existing code of ethics to the Academy that resolutions would be introduced at the last stated meeting relative to the election of resident Fellows. Those acting in this matter conceived that it was not only their right, but their duty, in the existing condition of the Academy, to introduce these resolutions, and to ask those who were known to agree with them to be present.

"The resolutions, which you have already published, were accordingly introduced by myself, and were carried by a vote of two to one. By recognized parliamentary procedure, which involved no abridgment of discussion, they were made as binding upon the Academy as possible."

A Card from the Ex-presidents of the Academy of Medicine.—Four of the five living ex-presidents of the Academy have published the following card in reference to the action of the Academy upon the resolutions introduced by Dr. Austin Flint, Jr.:

"We, the undersigned, ex-presidents of the New York Academy of Medicine, desire to record our approval of the action taken by the Academy at the stated meeting of April 19, 1883, reaffirming the ethical clause of its by-laws, and our endorsement of the course pursued, by request of the council of the central organization of the New York State Medical Association, as presented at this meeting by Austin Flint, Jr.

Willard Parker, M.D.,
President N. Y. Acad. Med., 1856.
James Anderson, M.D.,
President N. Y. Acad. Med., 1861 to 1867.
Austin Flint, M.D.,
President N. Y. Acad. Med., 1373 to 1875.
Samuel S. Purple, M.D.,
President N. Y. Acad. Med., 1875 to 1879.

New York, April 30, 1883.

SIR SPENCER WELLS.—Queen Victoria has signified her intention of conferring on Mr. Thomas Spencer Wells the honor of a baronetcy, in acknowledgment of "the distinguished services which he has rendered to the medical profession and to humanity." He was born in the year 1818, at St. Alban's, and was educated at Trinity College, Dublin. He gained his first medical experience in the Infirmary and School of Medicine, at Leeds, and subsequently studied in the Anatomical School, at Dublin, and at St. Thomas' Hospital. Having become an assistant surgeon in the Navy, he saw some active service, both afloat and ashore, before and during the Crimean war; and he was sent out in 1854-55, under the auspices of Mr. Sidney Herbert, as Chief Surgeon at Smyrna, and at Rankei on the Dardanelles. Returning to England at the close of the Russian War, he devoted himself to the study of that branch of professional science with which his name is associated, namely, ovariotomy, and connected himself with the Samaritan Hospital for Women. He is not only President of the College of Surgeons (in which capacity he delivered the Hunterian Oration last year), but a Fellow of the Royal Medical and Chirurgical Society, and Surgeon to Her Majesty's Household, and at the third centenary of the University of Leyden, he had conferred upon him the almost unique degree of an honorary M.D. He is the author of several important surgical works, especially on those improvements in operative surgery to which he has specially devoted himself.

SIR JAMES PAGET.—At a recent meeting of the Convocation of the University of London, SIR JAMES PAGET, was elected Vice-Chancellor of the University, to succeed the late Sir George Jessel.

HEALTH IN MICHIGAN.—Reports to the State Board of Health, for the week ending April 28, 1883, indicate that cholera morbus, erysipelas, typho-malarial fever, and rheumatism have increased, and that diphtheria, intermittent fever, and pneumonia, have decreased in area of prevalence.

Including reports by regular observers and by others, diphtheria was reported present during the week ending April 28, and since, at ten places, scarlet fever at eighteen places, and measles at twenty-two places.

THE SANITARY CONVENTION AT REED CITY, MICHIGAN, under the auspices of the Michigan State Board of Health, was held April 26 and 27, 1883, and was a very successful one, being fairly attended by the citizens of the place, by health officers of townships, cities, and villages in the surrounding countries, and by sanitarians from other parts of the State.

CEREBRO-SPINAL MENINGITIS IN CANADA.—The *Provincial Health Bulletin* for the week which ended April 28th, notes, with some dismay, the appearance of this disease in a sparsely settled district which forms the eastern shore of Georgian Bay, where it prevails to such an extent as to place it amongst the six prominent diseases. "It is to be fervently hoped that cerebro-spinal meningitis, widely epidemic in 1873, is not reappearing after a decade of quiescence. Further reports concerning it will be anxiously awaited."

ONTARIO BOARD OF HEALTH.—The first annual report of this board has just been issued by the Ontario Legislature, and contains many interesting details concerning the work of the past year; considerable progress has been made in the collection of statistics of prevalent diseases, and the weekly health bulletin, in the form of a map, has done much to interest the profession, and the public in these important questions of sanitation. Means have been taken to disseminate sanitary information partly by circulars and pamphlets, by public lectures, and by a health convention, which met at St. Thomas. Several important outbreaks of malaria, and typhoid fever, have been satisfactorily investigated. There are several interesting reports in the appendix, particularly those of Dr. Covernton, as commissioner to obtain sanitary information in Great Britian, and as delegate to the International Sanitary Congress at Geneva. Two admirable lectures, by the Secretary, Dr. Bryce, conclude a volume which gives ample evidence of the value to a community of a well-organized health board..

OBITUARY RECORD.—DR. ARCHIBALD S. TODD, of Wheeling, W. Va., recently died at an advanced age. He was a member of the American Medical Association, and had been engaged in the practice of medicine for almost sixty years.

NOTES AND QUERIES.

CORRIGENDA.

IN our issue of April 21, 1883, under the department of "Medical Progress," Jansen's article on "Anthropometrical Study of Fitness for Military Service," p. 385, 5, for "weight by half measure of height," read, "weight for each centimetre of height."

On page 515 in our last issue (May 5, 1883), it is stated that DR. H. P. C. WILLIAMS read a paper before the *Medical and Chirurgical Faculty of Maryland* on "Malarial Fever in Puerperal Women." It should have read, DR. P. C. WILLIAMS.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 30 TO MAY 7, 1883.

BAILY, JOSEPH C., *Major and Surgeon.*—To be relieved from duty in the Department of California, and assigned to duty in the Department of Texas.—*Par. 12, S O. 102, A. G. O., May* 3, 1883.

BIRST, VICTOR, *First Lieutenant and Assistant Surgeon.*—To be relieved from duty in the Department of the Missouri, and assigned to duty in the Department of Dakota.—*Par. 13, S. O. 102, A. G. O., May* 3, 1883.

BYRNE, CHAS. B., *Captain and Assistant Surgeon.*—To be relieved from duty in the Department of the South, and assigned to duty in the Department of the Missouri.—*Par. 12, S. O. 102, A. G. O., May* 3, 1883.

CRAMPTON, LOUIS W., *Captain and Assistant Surgeon.*—Now awaiting orders, to proceed without delay to Fort Wayne, Mich., and report to the Commanding Officer for duty at that post.—*Par. 2, S. O. 73, Department of the East, April* 30, 1883.

PAULDING, HOLMES O., *Captain and Assistant Surgeon.*—To be relieved from duty at Fort Sidney, Nebraska, and assigned to duty at Fort Douglas, Utah.—*Par. 1, S. O. 42, Department of the Platte, April* 25, 1883.

PERLEY, HARRY O., *Captain and Assistant Surgeon.*—To be relieved from duty in the Department of the East, and assigned to duty in the Department of Dakota.—*Par. 14, S. O. 102, A. G. O., May* 3, 1883.

SPENCER, WM. G., *Captain and Assistant Surgeon.*—Now awaiting orders, assigned to duty in the Department of the East.—*Par. 12, S. O. 102, A. G. O., May* 3, 1883.

TILTON, HENRY R., *Major and Surgeon.*—To be relieved from duty in the Department of the Missouri, and assigned to duty in the Department of the East.—*Par. 13, S. O. 102, A. G. O., May* 3, 1883.

WORTHINGTON, JAS. C., *Captain and Assistant Surgeon.*—To be relieved from duty in the Department of the East, and assigned to duty in the Department of the Missouri.—*Par. 14, S. O. 102, A. G. O., May* 3, 1883.

MACAULEY, CARTER N. B., *First Lieutenant and Assistant Surgeon.*—To be relieved from duty in the Department of the East, and assigned to duty in the Department of Dakota.—*Par. 12, S. O. 102, A. G. O., May* 3, 1883.

STRONG, NORTON, *First Lieutenant and Assistant Surgeon.*—Upon expiration of leave of absence, to be assigned to duty at Fort Thornburgh, Utah.—*Par. 2, S. O. 42, Department of the Platte, April* 25, 1883.

ORIGINAL LECTURES.

ON THE TREATMENT OF NÆVUS MATERNUS.

Abstract of a Clinical Lecture, delivered at the New York Post-Graduate Medical School.

BY JAMES L. LITTLE, M.D.,

PROFESSOR IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL, ETC.

GENTLEMEN: The patient I now present to you is about six months old, and has a small vascular tumor on the left side of the forehead. It is, as you see, of about the size of a hickory-nut. Its summit is of a bright-red color, while the outer margins of the tumor seem to be covered with healthy skin. On making pressure upon it with my finger, the swelling almost entirely disappears; and upon removing the pressure, it slowly assumes its former size. This tumor is what is known as a nævus. It is also known under the names of aneurism by anastomosis, or erectile tumor, or angioma. It is a disease of the capillaries. The mass of the tumor is made up of capillary vessels freely connecting with one another. The form here presented is of the cutaneous variety. Upon an examination of the abdomen of the child, we find another one of nearly the same character. It does not seem to be as deeply situated, however, for the integument does not form any portion of its covering. It is flatter than the one upon the face and somewhat larger. The surface presents a whitish appearance in several places, as if cicatrization was taking place. These tumors may occur upon any part of the body. They are congenital, and are frequently called mother's marks. When first noticed they are generally very small, but gradually become larger. In a certain number of cases they seem to disappear spontaneously. The one on the abdomen of the child seems to be undergoing this process of cure, the whitish spots on its surface being indicative of a change. The one on the forehead, however, the mother tells us, is rapidly becoming larger.

I have met with a large number of examples of this disease, and I have never failed to cure the cutaneous variety by the introduction of heated needles into the base of the tumor. If the tumor be small, one operation is generally sufficient; in larger tumors several operations may be required before the cure is complete.

I will now proceed to operate upon this case. But first, as to the needles used. It has always been my practice to employ a shoemaker's awl, which is slightly curved at the point and flattened. Such an instrument is much larger than the needles that are generally used for this purpose by surgeons. My assistant holding the child, I place the head between my knees, face upwards; in this way I have perfect control of its head, and am now ready to proceed. Another of my assistants holds the alcohol lamp at my right side, in which I heat the end of the awl to redness, and then plunge it into the tumor. The manner of introducing the awl is of importance. It should be thrust into the base of the tumor and towards the centre, not into the top. Holding it here a moment, I withdraw it and reheat it preparatory to a second introduction. There is scarcely any bleeding. This procedure is repeated until the entire circuit of the base of the tumor is completed. Please observe that I plunge the awl in at the juncture of the skin with the tumor and push it downwards and inwards. If punctures are made only in the top of the tumor, very little is gained by the operation. You should strive to destroy the vessels at its base. Having completed the circuit, I now make a few punctures in the most prominent part, over the surface of the nævus. The swelling has now become very much reduced in size. One of the punctures which I have just now made into the surface of the tumor is followed by a free flow of blood almost equal to an arterial jet. A second introduction of the needle fails to arrest the hemorrhage. Under such circumstances, you will find that the best method of arresting the bleeding, will be to make firm pressure over the bleeding point with a sponge for a few minutes. This I have never known to fail in stopping it.

The needle is introduced at a black heat; that is to say, although it is heated to redness in the flame of the lamp, before you reach the tumor the redness has disappeared. Although the child cried during the operation, it did not seem to be suffering very much, and now, that I have completed the operation, the patient has ceased crying. No special dressing is required. I generally advise, however, that the part be covered with a light compress, wet with cold water during the first night.

Two weeks later the patient was again brought to the clinic, when it was observed that a decided change for the better had taken place, the tumor having shrunk to less than one-third its former size. It was much flatter, and the redness over its surface had almost entirely disappeared, except at one or two points. Two or three additional punctures with the hot awl were made, it being introduced as before into the base of the vascular prominences rather than into their summits. It was predicted that the second operation would be all that was necessary to effect a cure, and that only a very slight cicatrix would remain.

There are two other ways of heating needles, namely, by means of galvano-cautery and Paquelin's thermo-cautery. The points coming with these apparatuses, however, are larger than the awl I have used, and the apparatuses themselves are clumsier and much more expensive than the simple alcohol lamp and shoemaker's awl.

ORIGINAL ARTICLES.

PLEURITIS, CIRCUMSCRIBED EMPYEMA, PLEURO-PULMONARY FISTULA; RECOVERY.

BY RICHARD McSHERRY, M.D.,

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE, UNIVERSITY OF MARYLAND.

ON the first day of May last, I was called to see a gentleman, a retired physician, verging on three-score years, whose prostration and general appearance indicated alarming illness. He informed me that he had been ill for some weeks; had taken advice from several physicians; and that he was then but just returned from the country, where he had gone with some indefinite hope of recuperation. His disease, he said, was all in his stomach; he was

perishing for want of food. Nothing was acceptable; nothing could be retained.

He had some fever; pulse and temperature ranging at the time at about 100 in frequency, and 100° F., respectively. He had a foul tongue; a fetid breath; a somewhat teasing cough, which added not a little to his gastric distress, and inclination to vomit. He said he had suffered greatly with pleurodynia throughout his illness, but that that pain was now giving him but little trouble.

As he lay helpless and reclining, I examined the front and sides of the chest; found the respiratory act very feeble, with some mucous râles; but percussion sounds clear, as far as I could then carry my examination, over front and sides of the chest. I took his word for the pleurodynia; but when, after a day or two, he told me a respectable physician had proposed paracentesis by aspiration, I inferred, of course, that there had been something more than pleurodynia. So far as my examination went, if there had been any considerable amount of pleuritic exudation, it must have been entirely, or at least largely, absorbed.

As the sequel will show, pleurodynia was quite a misnomer.

My first attention was necessarily given to the state of the stomach, that organ which the Knight of La Mancha, before Broussais, declared to be the laboratory in which the health of the whole body is tempered.

Whenever fetor of the breath is observed, the chlorates as a rule seem to be appropriate. I therefore gave moderate doses of chlorate of potash, combined with biborate of soda, and tincture of eucalyptus. I also directed cantharidal collodion to be applied over the stomach. Nourishment was only allowed to be offered in the blandest forms and in the smallest quantities, as in William Hunter's famous case.

As the stomach became somewhat tolerant, but the fetor continuing, a combination was given of eucalyptus, listerine, glycerine, and creasote. To these antiseptic agents, quinine and hyoscyamus were soon added for tonic and tranquillizing influences. For some aggravation of pain in the left side, a small blister was applied, and, for night-sweats, oxide of zinc and extract of belladonna were duly administered.

In the mean time, after some days of attention, the patient was enabled to sit up, by being supported, and I had an opportunity of examining the chest upon its posterior aspect.

The revelation gave something very different from pleurodynia. There was dulness, or rather flatness, under spine of the left scapula, radiating from two to three inches around the centre. Then some suspicious clicks were heard; and while the patient was sitting nearly erect, the percussion and respiration sounds were clear to base of lungs anteriorly. There was clearly no flow of fluid, seeking a level over the floor of the chest cavity.

The cough was then bringing up offensive sputa in limited quantities, when there came one morning a large gush of very fetid, dark, muco-purulent matter, the odor of which diffused itself beyond the rooms occupied by the patient.

Thereafter, the physical signs of a large cavity were complete. These were pectoriloquy, amphoric respiration, gurgling, and *inter alia*, as first noticed by my son, Dr. H. Clinton McSherry, occasional but unmistakable metallic tinkling.

The flatness, or effusion, never passed certain definite limits, so that it was clear we had a great abscess, or limited empyema to deal with. The disgorging went on freely after this, and alteratives, astringents, and tonics, always with antiseptic agents, were sedulously continued. Among the remedies, may be enumerated a combination of iodide of potash, muriate of ammonia, and sarsaparilla; sometimes at night, aromatic sulphuric acid, oil of tar, and glycerine, and occasionally terebinthinates and copaiba in capsules, tincture of iron and gentian, and for a time a combination of sulphate of quinine and hydrobromic acid.

Acid. hydrobrom. . . . . ʒj.
Elix. simpl. . . . . ʒvij.
Aq. menthæ, ... ʒj.—M.
Dose—Two drachms in tar water *ter in die*.

As convalescence advanced, cod-liver oil and lime water were directed for persistent use.

The patient was under my care from the first of May until the twenty-second of June, when he went, rather prematurely, I feared, to *Atlantic City*.

On the fourth of July I had the pleasure of receiving a note from him, announcing continued convalescence—gaining in strength, and in flesh, he said, nearly a pound a day. He had a good appetite. "I have no more cough, and the soreness in the left lung is scarcely perceptible, my sleep is undisturbed and natural, and I anticipate returning in a few weeks fully able to attend to business."

His anticipations were realized. I called to see him about a month ago, and had only an opportunity of making a hasty examination into his condition. Respiration and pulse were about natural; and I could detect only a little evidence of a mucous click occasionally over the original seat of disease. He was attending to his usual occupation (being now in the drug business), and expressed himself as in the enjoyment of perfectly good health. [I may here interpose that at a more recent visit the most marked physical sign was a pronounced *vocal fremitus* over the site of the original lesion.]

Let us take a view of the probable morbid anatomy of the case.

"Sometimes (in pleurisy) fluid occurs in the form of a circumscribed collection of pus between the pulmonary and costal, or diaphragmatic pleura, entirely shut in by adhesions. Such a purulent pleurisy, or empyema, is either fatal or may be absorbed; or may perforate the chest-wall, and escape externally; or may perforate the lung, and escape through a bronchus; or may perforate the diaphragm and find its way downward." (Delafield, *Hand-book of Post-mortem Examinations.*)

Orth gives more detail in regard to such cases.

"The pulmonary pleura," he says, "is at times the seat of *circumscribed necrosis*, as indicated by a yellowish-gray discoloration, friability, and softness; the lung-tissue beneath such spots is generally ulcerated or gangrenous. It is an interesting fact that these necrotic portions of the pleura always retain their smooth and reflecting surface, *i. e.*, show no signs of inflammation, although the whole surrounding membrane may be covered with a fibrinous deposit. Perforation may result from this process, the hole being usually from three to five millimetres in diameter, and a communication is thus established with the pulmonary lesion, which is usually a cavity. Certain peculiar changes in the appearance of the surface of the lungs are to be explained by the arrangement of the superficial lymphatic vessels, which, as is well known, lie between the vessels and form a supplemental network. These lymphatic vessels are subject to inflammatory changes of an acute as well as of a chronic nature; the latter give rise to a thickening of the walls, especially at the points of anastomosis (pseudo-tubercle), and to a dilatation of the vessels; the presence of puriform material within the vessels (purulent pleural lymphangitis) is due to an acute process." (Orth's *Diagnosis in Pathological Anatomy*. Translated by Drs. Shattuck, Sabine, and Fitz, of Boston.)

There may have been, perchance, as this author recognizes, embolic infarction (embolic pneumonia), producing an abscess at the periphery of the lung, the emboli being, or becoming, septic.

In septic suppuration, the cells are readily destroyed, and the fluid when examined under the microscope is found to contain little more than broken-down cells, detritus, and often large masses of micrococci. Or we may have a localized fibrinous pneumonia, associated with a fibrinous pleurisy, indicated, as Orth says, by the old term "pleuro-pneumonia," which term he thinks objectionable, as both catarrhal and cheesy pneumonia are very often associated with pleurisy, and might hence be included under the term. Cases, he says, also sometimes occur in which this order of things is reversed, and a primary pleurisy gives rise to fibrinous pneumonia in the adjoining tissue.

It would be difficult, if not impossible, to determine from the condition of my patient at the time of his coming into my hands, with a very vague history of the primary disease, whether the lesion passed from the lung to the pleura, or *vice versâ;* or whether there was embolic infarction; but all the indications pointed to circumscribed necrosis, while a circle of fibrinous deposit enclosed the broken-down vesicles and septic detritus, within limits not difficult of definition.

The Question of Operation.—A physician had proposed paracentesis some time before the patient came under my care; but the indications, at least when I took charge, were not clearly in favor of operation. There was no pointing, no evidence of approach to the surface; and, in fact, the obvious centre of disease was under the scapula.

That the pleuritic exudation was circumscribed, was clear from the fact that over the entire front of the chest, from apex to base, the percussion sounds were clear, whether the patient was lying on his back, or was in the erect position. There was no general empyema.

Dr. Bull, of Christiana, in commenting on artificial puncture of a pulmonary fistula, goes on to say, that the pathological changes in the lung which may indicate such an operation, are cavities of all kinds, such as limited gangrenous foci, pulmonary abscesses, phthisical and bronchiectacic cavities. The first two may be completely healed if the loss of substance be not too great; and if the remaining parts of the lung be sound, or capable of healing. With large cavities, a permanent fistula cannot perhaps always be avoided. Life may be preserved for a long time in cases of considerable gangrene and large pulmonary abscesses in many cases, when a permanent cavity is periodically emptied by coughing. It must, however, be distinctly better for these patients that the cavity should have an opening of discharge through the chest-wall, and that the passage should remain free; the constantly threatening decomposition of the contents of the cavity can thus best be obviated. Both gangrene and abscess of the lung may indeed heal without operation, but an operation should be performed when possible. Delay reduces the patient's strength, and favors the extension of the disease.

While conceding the propriety of operative procedures generally in all forms of empyema, I doubt if it would have been advisable in the case I am reporting. At all events, I was willing to await *empyema necessitatis*, and in the mean time relief came by disgorgement by way of the bronchial tubes.

In such a case as the following, recorded by Radek, a Pole, and quoted by Dr. Bull, the operation appeared to be eminently proper, and yet we cannot be sure that it did not hasten the fatal result.

A patient, æt. 44, entered hospital, suffering severely from dyspnœa. Two large communicating abscesses were found in the neighborhood of the right nipple. When pressure was made on them, the dyspnœa was increased, and pus was expectorated. The case was, however, believed to be one of empyema, communicating with a bronchus. An incision was made, and a large quantity of pus escaped; the cavity was washed out with carbolic acid. Relief followed for twelve hours; but after this acute pleuritis of the left side set in, and the patient soon died. The necropsy showed that there was no empyema, but a large abscess of the lung. (*Med. Gazette*, from *London Med. Record.*)

The whole question of tapping or making incisions into the chest for pleuritic, serous, or purulent exudation is one of very serious import. All physicians have not been rewarded with Dr. Bowditch's great success. The reader who would like to see the treatment of empyema, with the *dangers of thoracentesis and of injecting the pleural cavity*, fairly presented, may be referred to a capital article on the subject from the pen of Dr. Wm. C. Dabney, of Charlottesville, Virginia, in the *American Journ. of the Med. Sciences*, for October, 1882.

The dangers, indeed, are not great comparatively, and probably would be much less if carbolic

acid were entirely substituted by safer agents, used by way of injection.

As there are some dangers, the propriety of temporizing must always be considered. A gentleman from a neighboring county came under my treatment on the ninth of October last, with malarial fever. There was no history of pleurisy, but upon examining the chest, I found a large pleuritic effusion on the left side of the chest. He then remembered that acute pain in the same side had existed with chills and fevers, and anorexia and other preponderating evidences of malaria, which had caused the pleurisy to be overlooked. He had fever of the remittent form when he came into my hands. He had taken quinine freely up to that time. I continued this agent with effervescent draughts and saline aperients. Insomnia was troublesome, and was much relieved by the use of chloral and bromide of potash at night. The remittent soon became a tertian intermittent. Meantime, a fly-blister was applied to the affected side of the chest, but with general improvement there was no reduction of the pleuritic effusion. The urine was scant and high colored, but was free from albumen. Cream of tartar and cubebs were ordered as diuretics, and a succession of blisters, but no immediate impression was made. Two days after application of last blister, I took the aspirator to the bedside, but upon examining the chest preparatory to operation, I found so decided a diminution that I determined to postpone operation and continue medical treatment. Under this the patient continued to improve.

A very accurate investigator says that large blisters, like great surface burns, which are competent to produce ulceration of the duodenum, or even acute pneumonia or pleuritis, may have the effect of burns when allowed to draw thoroughly. The end organs of the sensory nerves in the skin are injured, he says, and the trophic centre is depressed. "Blisters, large, and long in action, are therefore proper only when the functions of the trophic centre are to be lowered. To this might be added, also, when the vaso-motor system is to be depressed. Conversely, transient irritation causes reflex contraction of the vaso-motor fibres, and excites the trophic system to acts that involve function only." (Prof. Bartholow, on "The Trophic System in Pathological Processes," THE MEDICAL NEWS, June 24, 1882.)

This passage is very suggestive. By my process of blistering, in the efficacy of which I have great confidence, the epispastic is removed when the skin is reddened, and the drawing is completed under warm fomentations or poultices. In this mode of use there is little danger of damage to the trophic centre, while stimulation and derivation are satisfactorily accomplished.

My patient passed from under my hands on the 10th of November, fairly convalescent, and with little remains of exudation. When this first occurred, paracentesis would certainly have been a justifiable practice to save the lung from prolonged compression; nevertheless, he improved, if not *cito*, at least, *tuto ac jucunde*.

I may here make a passing reference to another case of pleurisy, with a less satisfactory result. I was called in consultation by a physician in large practice to see an elderly man, with a large pleuritic effusion; and by and with consent of the practitioner, I aspirated, and drew off a large quantity of serum, of good appearance, which gave great relief to the sufferer. Some time thereafter, I was called again, and again aspirated. Upon this occasion the serum was clouded with pus. Again and again the aspiration was repeated, and upon each occasion there was an increase of pus. I suggested incision and drainage, but my friend did not approve. The patient removed to the country, and I did not see him for some weeks, when I was called to pay him another visit, and drew off a large quantity of almost pure pus, which was in no wise offensive. I again urged upon the doctor the propriety of incision, but he disagreed with me, and I saw the case no more. The patient was then running down rapidly. A large portion of the pleura had become converted into a great pyogenetic membrane.

Is the increase of pus-cells after paracentesis due to the aspiration? This is doubtful. It is usually supposed to be so; but, as Dr. Loomis remarks, "This is not a legitimate inference, for the increase in the cell development is the natural result of the morbid processes which were in operation at the first tapping." (*Lectures on Diseases of the Respiratory Organs, etc.*)

Not a great while after my last visit, I saw the death of the patient announced in the papers. I thought a free evacuation would have given him a better chance for life; or at least for improvement. Drawing off purulent matter from the pleura, and drainage and injection, are not yet among the certainties of therapeutic resources; but by all the laws of rational probabilities, such agencies, in such cases, must now be considered imperatively demanded.

Thus, it appears in the last two cases, that one recovered without operation, and the other died—probably—for want of a sufficient one.

BALTIMORE, March 8, 1883.

SARCOMA OF THE SPERMATIC CORD, WITH HERNIA OF THE VERMIFORM APPENDIX.

BY GEORGE W. MASON, M.D.,
OF BLOOMINGTON, ILLINOIS.

THE following case is reported because of the rarity of hernia of the vermiform appendix, and the still greater rarity of the complication of that condition with a sarcoma arising from the spermatic cord and surrounding the hernia.

P. B., colored; laborer; æt. about forty years, and unmarried. Says his health has always been good, except the present trouble. His family history, so far as is known, is good; there being no evidence of the existence of cancer, tumor, or any hereditary disease in the family.

While in the army he had a direct inguinal hernia, which was reduced, and for which he subsequently wore a truss. At times, since then, he has

had a hernial protrusion which he has always reduced himself.

The first symptoms of the present trouble appeared about two years ago, when he felt a soreness in the right groin. Later there occurred an aching pain in the right testicle. He ascribed these symptoms to partial descent of the hernia at times, and to the pressure of a poorly fitting truss of his own manufacture. In December, 1881, he first observed a tumor growing at the place where the spermatic cord emerges from the inguinal canal at the external abdominal ring. This was hard and at times quite tender.

A short time previous to his coming under my observation, he had consulted several physicians, under the belief that his hernia had "come down" so that he could not reduce it. He said that every means, except the knife, was used to effect its reduction. Forcible taxis was practised several hours, causing him great suffering. All efforts for its reduction proving ineffectual, he received no further attendance for five or six days.

On June 1, 1882, I was called, and found a tumor of considerable size occupying the lower part of the right inguinal region, and extending along the spermatic cord to the testicle. The testicle was movable upon the lower end of the tumor, which was hard, heated, and tense, showing signs of inflammation. There was no impulse communicated to it by coughing, nor any change in its size on muscular exertion or change of position. It could not be forced into the external ring to any perceptible extent. There was no gurgling, tympanitis, or fluctuation. The bowels had not moved for four days, but there was no vomiting. There was anorexia, and the tongue was furred and somewhat dry. The pulse was 100, and the temperature a little above normal.

If the tumor contained intestine, I concluded that a constriction must exist at the neck of the sac. For diagnosis, I administered a cathartic. The next day the patient was feeling much better; his bowels had been moved freely without any unpleasant symptoms in the tumor or elsewhere. The tumor was a little softer and showed signs of fluctuation. The treatment was an anodyne and flaxseed poultice to the tumor.

June 5.—A free incision was made, from which about four ounces of pus were discharged, leaving a cup-shaped tumor. The treatment was quinine and the tincture of the chloride of iron, with an anodyne when necessary. The poultice was continued. A discharge was kept up for about two weeks, at the end of which time there still remained an indurated tumor the size of a hen's egg. All further treatment failed to reduce it in size. Otherwise, the patient felt quite well. A suitable truss was adjusted in place of the one previously worn.

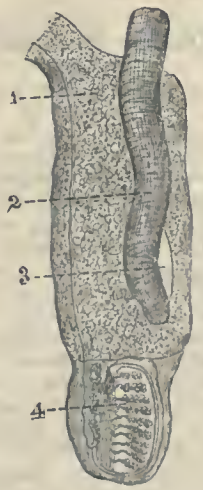
September 9.—The tumor was hard, firm, and much enlarged; the skin over it was quite tense. The patient was suffering intensely and wanted it "cut out." An opiate and a poultice were prescribed.

17th.—The tumor was very painful. The pulse and temperature were nearly normal. There was no evidence of inflammation. Upon consultation, and at the urgent request of the patient, it was decided that it should be removed at once.

On the same day, assisted by my colleague Dr. Lee Smith, I operated as follows:

The patient being etherized, an incision about three inches in length was made, commencing at about the point of exit of the spermatic cord from the external abdominal ring, and extending parallel to the cord down to the scrotum. The integument and fascia were carefully dissected from the tumor and testicle. At the hernial ring the convexity of a knuckle of intestine was seen presenting itself. This was readily pushed into the abdominal cavity. A round prolongation of the tumor extended through the hernial ring, which appeared like a pedicle, with some resemblance to intestine. It being firmly adherent to the mass, and there being no return portion to it, it was decided not to be intestine proper, but possibly the vermiform appendix. It was accordingly secured with a carbolized-silk ligature and divided, and the ligated end dropped into the abdominal cavity. A stout ligature was placed around the spermatic vessels and cord, and the growth severed high up, so as to include as much of the diseased structure as possible. A portion of the redundant scrotum was excised.

The tumor, as removed, including the testicle, was four and one-half inches long by one and three-



1. Body of tumor. 2. Vermiform appendix. 3. Sac containing pus. 4. Testicle.

fourths inch thick. It was somewhat kidney-shaped. Along its posterior and external portion extended the spermatic vessels and cord. Anterior to the middle was the vermiform appendix, about four inches of which were removed, and which extended to within an inch of the testicle. A small sac of pus was found anterior to and near the end of the vermiform appendix. Elsewhere it was adherent to the body of the tumor. Numerous bloodvessels existed throughout the growth.

Microscopic examination showed it to be a fibro-sarcoma, the outer portions being fibrous. The inner portion of body of the tumor was made up of

large spindle and stellate nucleated cells, contained in a homogeneous intercellular substance. Near the fibrous portion, this intercellular substance was in the form of fibrillæ, separating the individual elongated spindle-cells. The accompanying diagram shows the relation of the parts of the tumor.

The edges of the wound were united with carbolized-silk sutures and dressed with absorbent cotton, saturated with carbolized oil. The patient rallied without great shock, but considering his squalid abode and unhygienic surroundings, the prognosis was not good. Quinine was given freely, and the bowels were kept constipated for eight days with tincture of opium. At the end of that time they were moved by an enema. At no time after the operation was the pulse above 108, or the temperature above 101°. There was considerable suppuration around the ligature to the cord, which did not separate until the fourteenth day.

October 6.—The patient was walking around the house and yard. Pulse and temperature were normal. The wound was suppurating a little, but nearly healed.

At the present time the patient is free from pain, which was almost constant before the operation. The hernial opening has been completely closed by the cicatrization. There is some induration and enlargement in the groin, indicating that the growth will probably recur at that point. Otherwise he is in good health.

MEDICAL PROGRESS.

Treatment of Phthisis by Iodoform.—In the *Brit. Med. Journ.*, 1882, vol. ii. p. 169, Dr. Dreschfeld reported his first observations in the treatment of phthisis by iodoform. The favorable opinion then formed has been still further strengthened. Of sixty-four cases of confirmed phthisis, thirty-four had been under treatment sufficiently long to be available for the purposes of this communication. Of these thirty-four cases, four were in so far advanced a condition that the iodoform was only borne in the form of inhalation, but gave no results; two cases were complicated with amyloid disease, and here also the iodoform was useless. Of the remaining twenty-eight cases, ten showed either no improvement or only a temporary improvement (increase of weight, improvement of appetite, decrease of cough and expectoration); while the physical symptoms showed no alteration at first, but afterwards the phthisical process gradually advanced, and associated again with loss of flesh, night-sweats, etc. Of the remaining eighteen cases, some showed slight but steady improvement, broken only temporarily by a fresh cold or some complication, such as gastric catarrh, pleurisy, etc.; whilst in six cases the improvement was most marked and beyond all expectation, the increase in weight amounting in one case to fourteen pounds, in another to ten pounds, and in a third to eight pounds, in one month. The physical symptoms also improved; the sputa, however, continued to contain tubercle-bacilli. The iodoform treatment was also tried in six cases of incipient phthisis. Of these, two had only been under treatment a very short time. Of the four remaining cases, two showed no improvement, one was at once benefited; cough and expectoration entirely ceased, the apex-catarrh disappeared, and the patient felt now perfectly well. In the second case the treatment was equally successful—only, however, after having been continued for a longer time. There being an almost entire cessation of cough, it was difficult to obtain any sputa; one specimen, however, was obtained, and this was found free from bacilli, whilst before they were found abundantly. Two cases of laryngeal phthisis, treated both by inhalation, and also locally by the application of iodoform powder to the ulcers, gave satisfactory results; the ulcers cleared and became smaller, and the general condition improved. The iodoform was given in the form of pills (one grain of iodoform, two grains of croton-chloral, one minim of creasote) and in the form of inhalation (twenty grains of iodoform, twenty minims of oil of eucalyptus or ten minims of creasote, and half an ounce each of rectified spirit and of ether). The inhaler used was one devised by Dr. Roberts, consisting simply of horsehair matting, to the inner side of which was attached some flannel or cotton-wool, and on this the inhalation-mixture was dropped. The cost of the inhaler was about threepence. Where the pills were badly borne (especially in women), the iodoform was added to cod-liver oil. In very young children, iodoform inunction, made with olive oil or vaseline, was to be recommended, while older children seemed to take iodoform, either as powders or in small pills, very well. The good effects of iodoform seemed to consist in the following: 1. Increase of weight; 2. Increase of appetite; 3. Diminution of cough and expectoration; 4. Diminution or even total cessation of night-sweats; 5. The temperature was often a little lowered. No symptoms of iodoform intoxication had ever been seen. Several medical men, who had tried the iodoform treatment, had also obtained very satisfactory results.—*Brit. Med. Journ.*, April 28, 1883.

Idiopathic Spasm of the Tongue.—Dochmann reports (*St. Petersburger Med. Wochensch.*) a case of this affection in addition to the single case reported by Erb, and the two by Berger. A young girl, of nine years, had rhythmical spasms of the tongue at intervals of eight or ten minutes. During the spasm the tongue was not painful, but so much fatigued that when it was voluntarily stretched out it remained fixed between the teeth for a long time. It felt hard, was not convulsed, but sometimes, towards the end of the attack, would be bent over, as though the patient wished to lick her upper lip; then the tongue would be drawn back into the cavity of the mouth, with or without the will of the patient. The whole attack lasted eight to fifteen seconds; the longer, the greater the intervals between the paroxysms. During the paroxysms the tongue was continually struck against the teeth, causing much pain.—*Centralb. für Chirurg.*, April 21, 1883.

Pilocarpin and Homatropin.—Dr. Fronmuller states (*St. Peters. Med. Wochensch.*) that after injecting gr. ⅓ of hydrochlorate of pilocarpin under the skin of a syphilitic patient, severe symptoms of poisoning appeared within ten minutes. Perspiration and salivation were profuse, and the pulse rose to 120. All these symptoms disappeared within two minutes after the injection of gr. ⅛ of hydrobromate of homatropin, the pulse falling to 80. In two more cases the same antidotal effects were noticed. Dr. Fronmüller observes that it is very fortunate that we now know a ready and rapid remedy for the very alarming results that not rarely follow the employment of pilocarpin.—*London Medical Record*, April, 1883.

Nephrectomy. Rupture of the Vena Cava without Hemorrhage.—Lucke reports a case (*Deutsche Zeit. f. Chir.*, tome xv. fasc. 5 and 6, p. 518) of a man, æt. 60, in whom sarcoma of the kidney was diagnosticated. Laparotomy was performed; the capsule of

the tumor opened, and it was enucleated. While the tumor was being detached, it suddenly disappeared from the hands of the operator, and at the same time a gush of black blood escaped into the abdominal cavity. Compression with sponges and gauze arrested the hemorrhage, and the wound was closed. On the second day, symptoms of uræmia appeared; small pulse, vomiting, and diarrhœa; absolute anuria. Death, from coma, took place on the fourth day. At the autopsy, made by von Recklinghausen, there were found primitive carcinoma of the kidney, carcinomatous thrombosis of the renal veins, rupture of principal renal vein, and of the vena cava, closed by a large thrombus. The low pressure of the blood in the vena cava made the formation of a thrombus by simple compression possible. The other kidney had undergone sclero-cystic degeneration, which accounted for the sudden appearance of uræmia.—*Revue de Chirurgie*, April, 1883.

Trephining in Spinal Caries.—Dr. Banham and Mr. Arthur Jackson report this case: A healthy-looking boy, æt. 12, suffering from paraplegia, came under their care at the Sheffield General Infirmary, April 28, 1882. There appeared to be no strumous history. Was healthy up to January, 1882, when he found that his left leg dragged in walking; this was soon followed by dragging of the right. He had been struck in the back, about three years previously, with half a brick. At the time of admission, he could not use his legs at all; they were wasted and flaccid; sensation normal; exalted faradic contractility and sensibility and increased tendon reflex. There was no swelling or tenderness in the back; hot and cold sponges did not cause pain. His motions were passed normally at first, except that micturition was difficult. For the next two months, the symptoms grew worse, until he lost control over his sphincters, and was unable to turn himself in bed. The legs became drawn up in a state of tonic contraction. Faradism was painful, but galvanism was not felt. Sensibility was much diminished. There was exaggerated tendon reflex on both sides, and ankle clonus, both tests giving pain. There was no spasm, and no defined line of anæsthesia. The special senses were unaffected.

About two or three months after admission, a prominence was discovered in his back, corresponding to the lower dorsal spines. As his state became progressively worse, drugs and galvanism having no effect, Mr. Jackson, to whom the case had been for some time transferred, determined to explore the spinal canal at the seat of curvature, and see if he could remove the pressure on the cord; this was thought to be due to some inflammatory deposit on the back of the bodies of the vertebræ, which, having caused erosion of the vertebral ligament, had collected outside the theca in the form of pus.

The operation was performed on December 14, 1882, with full antiseptic precautions. An incision three inches and a half long was made over the lower dorsal spines. The laminæ and spinous process of a vertebra (the ninth) were removed; and the dura mater was laid bare, but not opened. No pus was found, but the spinal cord rose to the opening made in the bone.

The day after the operation, the temperature reached 102° Fahr., but fell during the next two days to 100° Fahr., where it remained for three weeks, with slight nocturnal elevations; after that it was normal.

The wound was dressed for the first time on December 26th, twelve days after the operation, and the sutures were removed.

On January 10th, fifteen days after the last dressing, the wound was again examined, and was found healed.

A week after the operation, the boy was able, for the first time since his admission, to micturate properly, and when he desired; he had control over his sphincters, for which result alone the operation had been of great value. The painful tonic contractions of his leg and thigh-muscles had quite disappeared, and he was able to draw his knees up against his abdomen, and slightly move his toes. Faradic contractility was, however, much dimished, though sensibility remained. He could distinguish with accuracy the point pricked with a pin at any part over each leg. His sensations also to touch, pressure, and temperature were normal.—*Brit. Med. Journ.*, April 28, 1883.

Muscular Atrophy after Typhoid Fever.—M. Deprès reports a case of this affection, occurring during convalescence from typhoid fever, in a young man, æt. 20. The right shoulder was prominent, the whole trunk was bent forward, and the vertebral column described a curve with a convexity toward the left in the dorsal region. Almost all the muscles were more or less atrophied. The treatment consisted in—faradization every day, every two days at least; gymnastics and physiological support by a special corset. The electricity was applied principally to the muscles corresponding to the vertebral curvature, but was not limited to these. The gymnastic exercises consisted principally in trapeze swinging, so as to elevate the body by the arms. The patient had markedly improved after eight days of treatment.—*L' Union Médicale*, April 19, 1883.

Copper as an Antidote to Epidemic Diseases.—M. Burq, after statistical research, thinks that there is almost absolute immunity to copper-workers in epidemics of cholera and typhoid fever. The statistics which he has collected seem to show that the storing-up of copper, in small amounts, in the animal economy constitutes an almost infallible protection.—*Gaz. Hebdom.*, April 27, 1883.

Physiological Action of Iodoform.—M. Rummo presented to the Academie des Sciences, a note showing the results of his experimental studies on this subject. 1. *Circulation and Respiration.*—In the frog, iodoform produces a considerable slowing of the pulse, and the heart is arrested in diastole. The crochet which is normally produced at the summit of the vertical systolic line is absent; there is also noticed slight ascension of the scale, and a slightly longer duration of the ventricular diastole; also the slowness with which the diastolic relaxation takes place. Large doses cause accelerated respiration at first, then slowing, and finally cessation. Certain irregularities of respiration were also noted. 2. *Temperature.*—Medium doses cause an elevation of 1° or 2°. Very large doses produce a transitory elevation, then a fall of 4° or 5°, notwithstanding the tetanus. 3. *Nervous System.*—In frogs, local anæsthesia, general feebleness, diminution of nervous, muscular, and reflex excitability, finally, general rigidity continuing after section of the cord. Death takes place in a state of complete rigidity. In mammifers the general nervous troubles take place when iodoform is injected into the stomach or peritoneal cavity. Being very insoluble, when injected under the skin it only produces local anæsthesia and very slight general phenomena. 5. *Digestive Tract.*—Large doses produce nausea, vomiting, and dysenteric stools. If not fatal there is hebetude, marasmus, and all the more advanced phenomena of iodism. Iodoform is eliminated by the urine in the form of an iodide, iodate, and hydriodic acid. It is found in all the organs and fluids of the body, especially the vitreous humor. 5. *Antiseptic Action.*—Iodoform does not arrest

the development of bacteria in the course of multiplication in putrid liquids, but a solution of it in spirits of turpentine kills bacteria in full proliferation.—*Gazette Hebdom.*, April 27, 1883.

TREATMENT OF FLOATING KIDNEY BY FIXATION.—DR. DAVID NEWMAN, of Glasgow, has performed, for the first time in Great Britain, the operation of nephrorraphy. The operation was performed in the following manner. The kidney was exposed by a vertical incision in the right loin, immediately external to the outer edge of the quadratus lumborum, and extending from the lowermost rib to the crest of the ilium; the capsule of the kidney was opened and stitched to the edges of the wound, and two catgut sutures were passed through the cortex of the kidney, the muscles, fascia, and skin, and secured externally by buttons. The patient suffered from severe symptoms, and was treated for several years without success; but, since the operation, the symptoms have entirely disappeared, and she has now almost recovered from the effects of the operation, which was performed three weeks ago.—*British Medical Journal*, April 28, 1883.

NEPHRECTOMY FOR SARCOMA OF THE LEFT KIDNEY.—HIGGUET reports (*Bull. de l'Acad. roy. de Belg.*, 1882, 3me série, t. xvi. p. 41) the case of a child of six years having an ovoid tumor, in the left hypochondriac region, as large as a small head, which had been growing for three and a half months. The tumor was but slightly painful on pressure, rather soft, dull, and without fluctuation; lateral displacement was very limited. No trouble in micturition, and no hæmaturia. Two months after the patient came under observation there was no change in the condition, except that the tumor had increased. Sarcoma of the left kidney was diagnosticated, and laparotomy was performed under antiseptics. The patient was well in thirty-six days. Microscopic examination showed that the tumor was an epitheliomatous adeno-sarcoma of the kidney.—*Revue de Chirurgie*, April, 1883.

EXTIRPATION OF THE THYROID GLAND.—PROF. KOCHER read a paper before the Twelfth Congress of the German Surgical Association on this subject. He has operated on 102 cases. He thinks it especially desirable to leave in place one of the connective-tissue envelopes of the tumor; by doing this, the removal of the tumor will be rendered more easy, and should suppuration occur, the product will be retained in the sac, and be more easily removed. All hemorrhage should be thoroughly checked, and the recurrent nerve must be especially guarded against accident. He does not think tracheotomy advisable: it increases the mortality, and with the exception of a small minority of cases in which there is danger of suffocation, it is of no particular advantage.

The degeneration of the tracheal rings, reported by many observers, he has never seen. Removal of the whole gland is, in his opinion, very unfavorable as to the ultimate results to the patient; for although retaining a healthy appearance, they are often attacked by a pernicious anæmia. The thyroid gland is, he thinks, a blood-forming organ, whose functions the spleen cannot perform.

In the discussion which followed, PROF. BARDELEBEN did not agree with Kocher as to the functions and necessity of the gland; he thought it more probable that the anæmia resulted from the goitre, and would have come on if it had not been removed. He had removed the thyroid gland and spleen from the same dog, and no such accident had resulted; the animal lived a number of years afterward (seven), and was accidentally killed.

PROF. MASS thought that the operation of extirpation of the thyroid for goitre was done too extensively; he thought that the majority of goitres would yield to an iodine treatment.

DR. WOLFLER, of Vienna, also read a paper upon the same subject. He called especial attention to the inconstant relations of the recurrent nerve to the inferior thyroid artery. In some cases, it was fastened between the artery and the tumor; he referred to the fact that the artery divides before entering the gland, and in many cases the nerve is embraced by two of the branches; and if the artery is ligated and divided before dividing into its terminal branches, the nerve will be torn when the tumor is removed. He showed that there had been five deaths out of sixty-eight cases operated on by Billroth during the past six years. Of the sixty-eight cases, twenty were between thirty and sixty-five years of age, and forty-eight between twelve and thirty. One death, occurring during the operation, was due to the entrance of air into the inferior thyroid vein.—*Berliner klin. Wochensch.* and *Deutsche med. Wochensch.*, April, 1883.

A NEW SIGN OF PREGNANCY.—JORISENNE finds that change of posture from standing to sitting or lying down, produces a variation of from ten to twenty beats in the radial pulse in non-pregnant women. In pregnant women there is no change in the frequency of the pulse whatever position the patient may be in. The importance of this sign, in the opinion of M. Jorisenne, is that it enables a diagnosis of pregnancy to be made as early as the first month, when there may be no other sign or symptom present.—*London Medical Record*, April, 1883.

TINCTURE OF ACONITE IN NEURALGIC METRORRHAGIA.—CHÉRON, noting the fact that metrorrhagia not infrequently bears a close relationship to lumbo-abdominal neuralgia, thinks that aconite is indicated, and prescribes it in the following manner; one drop of the tincture in a teaspoonful of coffee to be taken every fifteen minutes for six consecutive hours without eating anything in the mean while. On the next day, if the hemorrhage is modified, the same dose is taken in the same manner; if not abated, two drops must be taken every fifteen minutes. The maximum daily dose should never exceed forty-five or fifty drops. [Of course, Fleming's tincture is not here referred to.]—*Journal de Médicine de Paris*, April 28, 1883.

ADDISON'S DISEASE.—The latest contribution to the above subject consists in a concise essay by DR. BURGER, of Bonn (*Die Nebennieren und der Morbus Addisonii*). The writer sums up as follows: That structurally the supra-renal capsules should be classed with the blood-vascular glands, and they are not necessary for life. They have no connection with the cutaneous bronzing of morbus Addisonii; a pigmentation which is not peculiar to that affection, since it may be present in very different forms of cachexia. Diseases of the supra-renal capsules are not uncommon, and they very often run their course without producing the phenomena of Addison's disease. In Addison's disease the most varied forms of supra-renal capsular affection may occur; but when supra-renal disease is present, it does not contribute to the symptoms of Addison's disease, which depends upon an affection of the semilunar ganglia and solar plexus. This nerve change is generally brought about by disease of the supra-renals, the most frequent form of which is tuberculous inflammation. But the affection of the semilunar ganglia and solar plexus may be equally induced by disease of other organs, and may further arise spontaneously, so that the symptoms of Addison's disease may be produced apart from any change in the supra-renal capsules.—*Gaillard's Med. Journ.*, May 12, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MAY 19, 1883.

THE REACTIONS OF DEGENERATION.

BELOW we make some comments on a case of spinal lesion secondary to an injury of the sciatic nerve, reported from Charcot's clinic. In the course of that distinguished neurologist's remarks, he signifies his acceptance, in their entirety, of the observations of Erb on "the reactions of degeneration," and adopts the German symbols by which these reactions are given a mathematical mode of expression. Buzzard, the author of a recent work on a certain group of nervous affections, Ross, Bristowe, and other well-known English neurological authorities, have also expressed their concurrence in Erb's views, and in the formulated symbols by which he gives them concrete expression. Admitted thus by the best representatives of German, French, and English opinion, it may be safely conceded that the condition of nerves and muscles now known under the term—the reactions of degeneration—has a real existence. When the simplicity of these reactions, as regards their form and interpretation, is considered, the surprise is that they should have continued so long unknown. We owe to Erb, after the "polar method," the discovery—if so imposing a word can be applied to the recognition of the facts and their right explanation.

The first thing our readers not familiar with the phrase will demand of us is an explanation of the term—"reactions of degeneration." This will be readily comprehended if it is understood at the outset that nerves and muscles "respond" or "react" in a certain definite manner, when in a normal condition, to the stimulation of the galvanic and of the faradic current. In conditions of disease, the response or reaction is altered. The behavior of healthy nerves and muscles, when expressed in certain symbols, is entitled the "normal formula," and in disease there may be a complete reversal or a total abolition of the normal formula. It is quite impossible, in the limits of an editorial article, to give the details: we must content us with general statements.

Muscles stimulated directly, or indirectly through the motor nerve, by a galvanic current contract, on the making or closing, or on the breaking or opening, of the circuit. If the tension of the current be equal throughout, the muscles are quiet or relaxed during its passage. There are differences in the muscular action, according as the current is made or broken by the positive (anode) or negative (cathode) pole. The symbols now in universal use to express these normal reactions, are derived from the German words. The negative pole—the Cathode—is represented by Ka (Kathode), and the positive—Anode—by An (Anode). The opening or breaking of the circuit is O, from *Oeffnung*, opening; and closing or making the circuit is S, from *Schliessung*, closing. It follows that the symbols for opening and closing the circuit with the anode or cathode will be AnO, anodal opening, and AnS, anodal closing; and KaO, cathodal opening, and KaS, cathodal closing. As muscular action takes place on opening and closing the galvanic current, it follows that there must be a symbol to express it. The word *Zuckung* signifies contraction, and hence the symbol Z. When the contraction is normal, the symbol Z is used; when strong, the symbol is an accentuated Z'; when weak, a small letter is used, as, for example, z; and when tetanic, Te. There are three several grades of action in which the results of stimulation of motor nerves by the poles are expressed in the formulæ. There is, first, the weakest current, which will cause a muscular contraction — a cathodal closing contraction = KaSZ; but no contraction from the anode. Next, the current which causes stronger contraction on cathodal closing, KaSZ', but no contraction on opening; whilst the anode induces slight contractions both on opening and closing = AnSz, and AnOz. Third, which is the highest, the current causes a tetanic contraction on cathodal closing, and a feeble cathodal opening contraction, KaSTe, KaOz; also, on anodal opening and closing, there are decided contractions, AnOZ, AnSZ.

Such are the normal formulæ; in other words, such are the symbols by which we express the normal reactions of the motor nerves and the muscles on stimulation by the galvanic current. We have now to consider the modifications made in

these by disease. It is the merit of the distinguished Professor at Heidelberg, to have clearly set forth these modifications—to have rightly interpreted their significance, and to have indicated the treatment necessary. Injury to the motor nerves, or to that segment of the spinal cord from which the nerves take their origin will set up the reactions of degeneration. Erb, strongly and justly, insists on studying the nerves apart from the muscles. In the case of injury or disease of the motor nerves, at first there is, as a rule, an increase of electric excitability, but then a quantitative decline ensues, and if the injury is complete and not remediable, by the twelfth day the electric excitability disappears. When the disease is in the spinal cord or motor nerves, changes occur in the excitability of the muscles to the faradic current. In about a week after the paralysis appears in the muscles they begin to decline in their faradic excitability, which is soon after extinguished, and is permanent in incurable cases, but when regeneration of the nervous elements can be effected the muscles regain, but never wholly, their power of response to faradic excitation.

Very different is the behavior of the paralyzed muscles to the *galvanic* current. At first the excitability of the muscles declines to the galvanic current as it does to the faradic, but after the first week the galvanic excitability increases, so that in a few weeks a feeble current which would not in health move the muscles, now causes lively contractions. Besides the increase in galvanic excitability, qualitative changes ensue in the law of muscular contraction, and at length the normal formula is reversed. To these quantitative and qualitative changes in the muscular contractions chiefly belongs the term—the reactions of degeneration. Their diagnostic significance is great. Indeed, it may be affirmed that, without the application of these principles, a correct diagnosis of spinal and nerve lesions becomes impossible. That Charcot admits the importance of these principles by applying them closely in the investigation and treatment of disease, is the fact which we desired to impress on our readers by the editorial comments below.

In a recent clinical lecture on a case of spinal lesion secondary to a contusion of the sciatic, Charcot confirms the views of Erb regarding the electric reactions of the affected nerves and muscles. Not only so, but he adopts Erb's phraseology, and the German words on which the symbols are based. Charcot, also, emphasizes the value of these electric reactions in diagnosis and in prognosis.

The points of interest in this case are two: the results of the contusion; the admirable skill with which the spinal lesion is demonstrated. Given a contusion of the greater and less sciatic nerves on one side, there followed an extension upward of the neuritis, and a secondary implication of the spinal cord. The spinal affection is demonstrated by the paralysis of the sphincters, the loss of genital power, and the weakness of the muscles on the injured, and on the side opposite the injury. The condition of the parts—especially of the nerves and muscles—is most clearly shown by the electrical reactions, Erb's reactions of degeneration. The precise seat of the spinal lesion is also thus mapped out. By a methodical exploration, with both faradic and galvanic currents, not only is the whole affected area ascertained with exactness, but the prognosis and therapy are clearly indicated.

FAT EMBOLISM.

While it is vaguely known to physicians and surgeons that emboli composed of fat are occasionally found in the bloodvessels of the lungs, especially in diabetes mellitus, and certain crushing injuries to bone, it has perhaps not occurred to many that they may be a cause of death after injuries to the soft parts. Such would seem to be the fact according to some recent observations by Pinner, published in *Berliner klin. Woch.*, of March 26.

A man, aged 61, was run over by a heavy wagon, fracturing the head of the left fibula, and tearing it from its tibial attachment. The soft parts were much lacerated and the skin undermined; the peroneal nerve was torn from its position, and lay exposed for from three to four centimetres. Out of the enlarged wound flowed a considerable quantity of blood mixed with a conspicuous amount of fluid fat, which, upon cooling formed upon the surface of the leg a thick, stiff layer. On the fourth day, he became restless, and although quieted by morphia did not sleep. At the morning visit, his face was pale, death-like, he spoke in a whisper, though consciousness remained; and he complained of the dressings being tight, although this was found not to be the case, and the wound was still healthy. The pulse was accelerated, 108, small, easily compressible; respirations 24, loud and deep. Later, the latter became deeper, the pulse more frequent and irregular, the extremities cold and moist. Still later the radial pulse was imperceptible, the heart sounds scarcely audible, respirations frequent and shallow, and he died at the end of four days.

At the *autopsy*, in addition to the lesions described, the subcutaneous tissue of the lower third of the thigh, as well as the upper third of the leg, was distended with blood, partly fluid and partly coagulated, but the joint was unopened, and the great vessels were intact. The brain was free from

important changes, except the sinus at the base contained, in addition to partly fluid and partly coagulated blood, fat drops, not numerous but clearly recognized. At the apex of the right ventricle, otherwise almost empty of blood, was a loose clot, on the surface of which a small quantity of fat was clearly discernible. The left auricle was filled with a loose clot in which there was a large amount of fat, while the left ventricle contained little blood, but a large quantity of fat, so that the inner surface of the blood-stained ventricular wall appeared as if covered with dew-drops.

On microscopic investigation there was found to be extensive plugging by fat of the bloodvessels of the lung, those of large calibre as well as the finest capillaries, resulting in some places in the most exquisite capillary injections about the alveoli. In a few glomeruli, also, of the kidney, individual loops were similarly injected, but nowhere else was fat found.

The source of this fat, Pinner believes to have been the subcutaneous connective tissue which was rich in fat, and which in his view has received too little attention in the study of fat embolism. It could certainly not have originated in the broken bone, which was a small one, and contained a scanty and thin medullary substance. According to the experiments of Scriba upon animals, extended to human pathology, it would be necessary that two hundred and ten grammes of fat should enter the circulation to cause the death of an adult. Now it is calculated that the femur of an adult man contains but seventy grammes of fat, so that some other source than the bone must be looked for. This must be contributed by the soft parts, which are always more or less injured in fractures.

That the death in this case was due to fat embolism there seems to be no reasonable doubt. There were no symptoms of death from the injury itself, as those of collapse; nor were there any of septicæmia. Nor did the autopsy furnish any facts pointing to either of these causes. On the other hand, there was evident embarrassed respiration, such as would be expected from obstruction of the bloodvessels of the lungs.

We would suggest to our pathologists, who may have the opportunity of making autopsies in cases of death after injuries, that they seek for evidences of the presence of this, as yet imperfectly studied, cause of death.

DIABETIC PHTHISIS.

Many cases of diabetic phthisis have recently been reported in the German journals, in which tubercle-bacilli have been invariably found in the cavities in the lungs. The natural inference from these facts is that the diabetic constitution is favorable soil for the fixation and development of tubercle-bacilli; as well as that the phthisis of diabetes is identical with ordinary phthisis—in other words, is a true tuberculosis.

Franz Riegel, of Giessen, communicates an observation (*Centralbl. f. klin. Med.*, March 31, 1883) which inclines him to believe that the diabetic is subject to another form of phthisical process, which is non-tuberculous in its nature, and that this may be diagnosticated during life, although he admits that his position has not, as yet, been confirmed by an autopsy.

Four cases of diabetes have recently been treated in his medical clinic. Of these, two presented no lung symptoms, while two did. In the sputum of one of these last, numerous tubercle-bacilli were found. In that of the other, although there were the most distinctive signs of infiltration of the lung apex, and although more than fifty preparations were investigated with the greatest care, no bacilli were ever found. Ever since the discovery of the bacillus by Koch, it has been the practice in this clinic to examine in all cases for the bacillus, so that the charge of inexperience cannot be brought. The sputum presented unusual characters, rather those described by Leyden as characteristic of abscess formation.

From the above observations, Riegel concludes that there does occur in diabetics another form of phthisis, which has nothing to do with tuberculosis, and which may be clinically distinguished from it by the absence of bacilli from the sputum. Morbid anatomy, in fact, confirms this position; for it has been found that in addition to the ordinary form of phthisis, there also occurs in diabetics a chronic fibroid pneumonia with ulceration. Such a pneumonia Marchand described in the right apex of the lung of a diabetic twenty-one years old, in which there were in addition to the fibroid changes, several smooth-walled cavities, as large as a cherry, but no tuberculous or cheesy change. In such a case, tubercle-bacilli would be constantly absent from the sputum, which would also contain the morphological constituents characteristic of abscess of the lung.

THE INCONTINENCE OF RETENTION.

The veteran Prof. Gross never used a happier phrase than this to designate a pathological state of frequent occurrence, and yet often wholly misunderstood. Some time since we saw a gentleman from a neighboring State who had "incontinence of urine," and the urinary odor about him was both diagnostic and disgusting. For six years he had never gone to bed without a bowl between his thighs to catch the dribbling urine—this, too, in spite of the fact that he was compelled to rise a dozen times during the night to void his urine—and the

numerous accidents that had occurred can be readily imagined. He had been under medical care during all this time, yet no one had ever tried the simple experiment of catheterization! After emptying his bladder of all he could pass (four ounces), the catheter drew off thirty-two ounces more! The diagnosis and the treatment were equally plain, and the result in every way gratifying.

But the consequences of such neglect may be far more serious than mere discomfort and disgust. The cause of the incontinence is, of course, an overfull bladder from atony of the bladder, or more frequently from some form of obstruction. This may be followed by all its usual consequences, such as vesical hypertrophy, decomposition of the urine, cystitis, dilatation of the ureters, and renal disease. A very striking case of double hydronephrosis, due to an enlarged prostate and its resulting retention, has been lately published by Dr. D. W. Prentiss, of Washington. The catheter, had it been used both for diagnosis and treatment, as pointed out by Dr. Prentiss, would have prolonged his life in comparative comfort, but its neglect allowed great dilatation both of the bladder and ureters, with fatal mischief to the kidneys.

Indeed, it may be laid down as a rule that, in every case of incontinence, the prostate should be examined and the catheter should be used. Especially should this be done in old men, and in cases in which any supra-pubic dulness exists. The operation is so trivial as to pain and danger, that no excuse ought to be allowed. Of course, if prostatic enlargement or stricture exist, the catheterization may not be a trivial operation, but the diagnosis will be established, and a rational treatment will then be instituted.

The above will be to many of our readers trite and common-place. But it has seemed to us worth while to call attention anew to the subject in consequence of the frequency with which we have lately seen cases of retention, followed by urinary overflow, in which incorrect diagnoses were made, chiefly, from neglect to use the catheter.

THE BACILLUS OF GLANDERS, AND ITS DIAGNOSTIC VALUE.

LOFFLER and SHÜTZ first showed that glanders in animals was accompanied by a special form of bacillus, and that these bacilli were found in specially prepared sections of the nodules of glanders, found in the liver, spleen, lungs, etc. In size, they resemble very closely the bacilli of tuberculosis. These bacilli, after culture in blood-serum, reproduced glanders in animals inoculated by them. Recently WASSILIEFF (*Deut. med. Woch.*, March 14) had an opportunity to study the blood and pus from pustules and nasal secretion from a postillion who had acquired glanders. In all of these (with powers of 900 to 1,300 diams.) he found the bacilli above named. He found them most abundant in the contents of the unripe pustules. Almost all the bacilli contained spores, for the most part four, but sometimes five and six, in which latter case they were somewhat larger. These rod-shaped organisms appeared for the most part singly, more seldom in groups of two and three.

Now, the primary symptoms of glanders are so slightly characteristic, even if infection be suspected, that the diagnosis is often extremely difficult, especially where the lungs or skin are primarily affected; and weeks often elapse before it can be definitely made. The presence of this vegetable parasite, in the different secretions, if shown to be essential and constant, will of course be of signal service in detecting a disease whose early recognition is of great importance in consequence of its highly contagious character.

IN our editorial upon Koch and his American critics, published some weeks since, we say, "Of Sternberg, Koch disposes summarily by saying that because he could not find the bacilli he denied their existence." We were, of course, quoting Koch, without expressing any opinion of our own. In point of fact, Dr. Sternberg was among the first to discover the bacillus in the sputum of phthisis treated by Ehrlich's method, although he failed, as many others did, with the method first published by Koch. Sternberg announced this fact in THE MEDICAL NEWS of September 16, 1882. Our object was simply to show how Koch treated those whom he called his critics. In point of fact, Dr. S. can hardly be called a critic of Koch, since he not only found the bacilli in sputum, but also, repeating Koch's inoculation experiments upon guinea-pigs and rabbits, succeeded in a certain number of cases. These results he likewise published in THE MEDICAL NEWS for Dec. 20, 1882.

We take pleasure in recalling these observations of Dr. Sternberg, because we fear that some of our readers may have construed Koch's criticism of him as our own, and any such erroneous impression we desire to correct.

THE Fifth Annual Congress of the American Laryngological Association will be held in the Hall of the Academy of Medicine in New York on Monday next and the succeeding days, under the presidency of Dr. George M. Lefferts, of New York. The programme of the meeting, which has just been issued, contains the titles of twenty-two papers, which give promise of proving of more than usual interest to this year's proceedings.

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Thirty-first Annual Session, held at Norristown, May 9, 10, and 11, 1883.

(Specially reported for THE MEDICAL NEWS.)

(*Concluded from p. 545.*)

THURSDAY, MAY 10TH.—SECOND DAY.

MORNING SESSION.

THE PRESIDENT announced that discussion of the previously read papers was in order.

TREATMENT OF CARCINOMA OF THE BREAST.

DR. CHAS. B. NANCREDE, of Philadelphia, said that he wished to endorse the remarks which had been made upon the treatment of carcinoma. He was induced to speak from the great importance of the subject of Dr. S. W. Gross' paper. It would be a matter of surprise that the manifest advantages of the method of operating advocated by Dr. S. W. Gross were not universally recognized, were it not that our *a priori* theories controlled our practice. Those who believe in the constitutional origin of cancer, of course, do not approve of such apparently severe operations. When the disease recurs after partial removals, they adduce the cases as proofs of the truth of their views. Mr. Moore, of London, many years since, pointed out the effect of these inadequate operations upon our theories of cancer, and advocated more radical measures. He then reported a case of a young married woman, whose right breast he had removed for carcinoma within three months after the first appearance of the disease. It started during pregnancy, and the axillary glandular growth was larger than the primary mammary tumor. He had freely removed everything, and had bared the axillary vessels for some distance. The patient, at the end of nearly two years and nine months, is still perfectly free from local or general recurrence. Three well-known microscopists had confirmed the diagnosis after careful examination of the specimen. Experience has shown that partial removals of the breast are, in reality, more dangerous than complete excisions. Dr. Nancrede believed that by discarding the use of the knife, and substituting the fingers, or dull-pointed curved scissors, after the axilla is opened, any ordinary operator could proceed with safety. He had thus bared the axillary, carotid, and femoral arteries with impunity. He thought that even with all its dangers of blood-poisoning, etc., the free drainage, by obviating intra-traumatic pressure, more than counterbalanced the severity of the operation.

Under the head of

NEW BUSINESS,

the CORRESPONDING SECRETARY read the report of the case of Dr. D. S. Hays, of Hollidaysburg, Pa., *vs.* Blair County Medical Society. The Board of Censors of the Sixth District of Pennsylvania, after carefully considering the case, dismissed the appeal.

A communication was read, by Dr. Hiram Corson, from the American Anti-Vivisection Society, asking that the State Medical Society give attention to the matter of vivisection.

On motion of Dr. J. T. Eskridge, a committee of five persons was appointed to consider this subject, and to report at the next meeting of the Society. The President subsequently appointed the following members to serve on the Committee: Drs. Hiram Corson, E. A. Wood, Wm. S. Little, S. Weir Mitchell, and H. C. Wood.

The announcement of the members of the Nominating Committee from the different counties was made as follows: Adams, A. Noel; Allegheny, T. J. Gallaher; Armstrong, R. L. McCurdy; Blair, W. R. Findley; Bradford, E. P. Allen; Bucks, Joseph Foulke; Cambria, M. J. Donnelly; Centre, Philip S. Fisher; Chester, Edward Jackson; Clearfield, S. C. Stewart; Columbia, L. B. Kline; Crawford, G. O. Moody; Cumberland, R. L. Sibbet; Dauphin, Hugh Hamilton; Delaware, I. N. Kerlin; Erie, J. L. Stewart; Fayette, Ellis Philip; Franklin, John Montgomery; Huntingdon, A. B. Brubaugh; Indiana, T. B. Ansley; Jefferson, W. M. B. Gibson; Lancaster, J. A. E. Reed; Lackawanna, J. W. Gebbs; Luzerne, Louis Taylor; Lycoming, John W. Young; Mifflin, A. Rothrock; Montour, S. S. Schultz; Northampton, C. McIntire, Jr.; Philadelphia, W. G. Porter; Schuylkill, J. S. Callan; Snyder, J. H. Kanawell; Venango, S. Gustine Snowden; Warren, F. A. Shugart; Westmoreland, J. A. Fulton; York, W. S. Rowland.

PROF. S. D. GROSS offered the following resolutions, which were adopted, concerning the

APPROPRIATION FOR THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE AND MEDICAL MUSEUM.

Whereas, This Society has observed with regret that the bill reported in the last session of Congress by the Committee of Public Buildings, recommending the erection of a fire-proof building to contain the library and museum of the Surgeon-General's Office, was passed over in the pressure of business, and

Whereas, The medical profession of the whole country is interested in the preservation of the same, therefore be it

Resolved, That in the opinion of this Society it is the urgent duty of the incoming Congress to provide for the erection of a suitable fire-proof building to receive the Library and Museum above named, so that the books and specimens may be safely kept and made easy of access.

Resolved, That this Society strongly deprecates any change from the present management of the Library and Museum, and, above all, the severing of these collections by the merging of the power into the National Library as destructive of its utility.

Resolved, That it is highly to be desired that Congress should make a sufficient annual appropriation to admit of the purchase of all new medical books and journals wherever published, in order that this, the library of the medical profession of the United States, may manifest its usefulness. It is further recommended that authority be given to complete the *Index Catalogue*. And it is further

Resolved, That the members of the Society will regard it as a duty to impress these views, either personally or by letter, on such senators and members of Congress as they may be acquainted with, and that a copy of these resolutions duly authenticated, shall be sent by the Secretary to each representative and senator from this State.

DR. W. W. KEEN offered the following:

Resolved, That the Medical Society of the State of Pennsylvania, in view of the very urgent need of enlarging the facilities for dissection, both in the medical schools of Pennsylvania, and also by physicians throughout the entire State—a privilege now denied—most earnestly urge upon the Legislature of Pennsylvania, of the passage of the pending Anatomy Bill, as now before the House in its amended form.

This was carried unanimously, and on motion of Dr. Roberts, it was directed to be sent to the Legislature, with the signature of each member of the Nominating

Committee, as well as the President and Secretary of this Society. The following report of the Nominating Committee was then presented, and adopted, which is equivalent to election.

The following were chosen

OFFICERS FOR 1884.

President.—Henry H. Smith, of Philadelphia.

Vice-Presidents.—Ellis Philip, of Fayette; H. B. Van Valzah, of Clearfield; J. W. Kerr, of Allegheny; S. S. Schultz, of Danville.

Permanent Secretary.—William B. Atkinson, of Philadelphia.

Recording Secretary.—Morris S. French, of Philadelphia.

Treasurer.—Benjamin Lee, of Philadelphia.

Corresponding Secretary.—John G. Lee, of Philadelphia.

Philadelphia was fixed as the place of meeting next year, and Dr. John B. Roberts was appointed Chairman of the Committee of Arrangements.

AFTERNOON SESSION.

The Treasurer's annual report was read. The balance on May 11, 1882, was $1965.68, and the receipts during the year were $2269.91. The expenditures were $1871.75, leaving a balance in the treasury at this time of $2363.84.

The Treasurer announced that the County Societies of Lehigh and Bradford, had forfeited their membership by non-payment of dues.

The report contained the following resolution containing the

PUBLICATION OF THE TRANSACTIONS,

which was also adopted.

"*Resolved*, That this committee recommends that the publication committee be instructed to have the *Transactions* of the Society printed, and ready for distribution within three months from the date of final adjournment of the Society."

By request of the committee on publication, the following was subsequently adopted:

"*Resolved*, That all manuscript for publication in the volume of *Transactions* for this session, be required to be in the hands of the committee by June 1, 1883, or be omitted."

DR. GEO. O. MOODY, of Titusville, in the

ADDRESS IN OBSTETRICS,

reviewed the principal events which marked the progress of this department during the last five years. He insisted, at the outset, upon the participation of every organ and fibre of the pregnant woman in the parturient process, and declared that the responsibility of the accoucheur did not cease with the safe delivery of the child, but that it continued until the reëstablishment of the health of the mother.

Referring to abortions, the large mortality he declared to be due principally to retained secundines and consequent hemorrhage. Expectant treatment here is to be condemned, the immediate and complete evacuation of the uterus by dilatation, forceps and the curette is the only protection against bleeding, septicæmia, and other accidents. Authorities advise that the tampon should, as a rule, be discarded in favor of the sponge tent, where threatened collapse prevents immediate attempts at removal of retained placenta; in cases where the hemorrhage is treated *early* by the tampon, the secundines may be discharged from the uterus and removed with the tampon, which in such cases becomes a safe and valuable aid in dilating the os and exciting contraction. If this result is not obtained within thirty-six hours, the lecturer advised to delay no longer, but to proceed at once to dilatation and complete evacuation of the uterine cavity, the finger being the safest instrument, but the curette, and placenta-forceps are sometimes indispensable.

In discussing the obstetric forceps, Tarnier's instrument was described, and spoken of with praise, but it was not considered essential to the armamentarium of the practising physician, as it is only safe in experienced and familiar hands. From his own experience, he regarded the simpler forceps all sufficient. Out of nineteen hundred cases of childbirth, taken from the practice of Dr. Geo. W. Barr, a former colleague, and himself, there were forty-one cases of forceps delivery, without any discovered lesion of the parturient canal, except an occasional ruptured perineum.

With regard to puerperal convulsions, he made a distinction between the nervous form and an apoplectic form; the former generally recover, the latter generally do not, in the latter venesection and cathartics are often serviceable. In the uræmic form the treatment to be pursued is that usually directed to acute nephritis—hot bottles, wet pack, etc., externally, and chloral hydrate internally, with other remedies that may appear indicated. Early delivery was recommended.

Support of the perineum during delivery was considered as an efficient means of preventing rupture of the perineum. The treatment of cases of extra-uterine pregnancy by electricity was referred to in terms of commendation, as affording hope of recovery to cases otherwise hopeless.

Speaking of oxytocics, he said the newly discovered ergot alkaloid (chalbazian of Paris), given hypodermically in doses of one-fiftieth of a grain, promises to be of great value on account of its very prompt action. Quinine, though valuable in uterine inertia, is not sufficiently active to make its use dangerous for malarial attacks during pregnancy.

Lacerations of the cervix uteri are not only a frequent cause of sterility, but may give rise to epithelioma. The caution is given to the accoucheur in the use of forceps within the os, not to proceed too rapidly, but to exercise the same precaution against laceration as he does with the perineum. Anæsthetics in precipitate labors and opium in the tedious first stage of labor, are also valuable adjuncts.

Post-partum hemorrhage caused the death of four hundred and ninety-one women, in Great Britain during 1881, and many who survived suffered with ill-health for a long time afterwards. Electricity is preferred to styptics, but in cases of threatened death, iron injections may be resorted to with proper precautions. The introduction of the hand as recommended by Thomas, or vinegar injections, are often efficient, and are safer than the iron.

In placenta prævia, he recommended the tampon, formed of a conical linen bag stuffed with carbolized cotton.

The address closed with a consideration of antiseptic midwifery and its relations to puerperal fever. The various conditions of the patient which predispose to fevers, particularly post-partum hemorrhage, were referred to; and the need of systematic use of disinfectant injections, and antiseptic cleanliness around the lying-in chamber were strongly insisted upon. The hands and every instrument which comes in contact with the parturient canal, both before and after labor, should be thoroughly and carefully disinfected.

In the treatment of puerpural septicæmia and pyæmia, daily vaginal washes of carbolized water or other disinfectant, and hypodermic injections of phenic acid or oil of eucalyptus had been followed by recovery.

DR. HENRY LEFFMANN, of Philadelphia, then delivered

THE ADDRESS IN HYGIENE.

Hygiene, he said, although a science recognized by the earlier physicians, has found extensive develop-

ment as a specialty only of late years. The superstitions of past times have usually obstructed all attempts at preventive medicine, but at the present the mass of the community recognize disease not as a visitation, but as a natural result of violations of natural laws. The practical study of the causation of disease is a feature of modern research, and although sanitarians are divided in opinion as to the correctness of the so-called germ theory, these differences do not offer any obstacle to true sanitary reforms, since all are agreed that cleanliness and pure air are the essentials to public health. The most serious hygienic errors of the day, are the dread of exposure to the vicissitudes of the weather, and a disposition to attach too much importance to the danger of taking cold. Quotations from writers on hygiene were given to show that severe exposure can be borne with advantage, also details of special cases illustrating the same fact. While many cases of disease arise from various excesses, many others undoubtedly owe their origin to exaggerated fear of "drafts" and "night air," this fear finding special expression in the close and badly ventilated condition of our bed-rooms.

Voluntary papers were now in order.

DR. SAMUEL W. AYRES, of Pittsburg, read a very able paper on

OUR ASYLUMS AND OUR INSANE,

in which some details of management and administration of the internal affairs of these institutions in their direct bearing upon their inmates was discussed, and criticisms and suggestions of improvement made.

With regard to the superintendent, it was said that "there is no disguising the fact that a superintendent cannot be at the same time purveyor, farmer, florist, horticulturist, paymaster, clerk, steward, financier, board of managers, lobbyist, etc., and practising physician. It is simply preposterous, and yet it is daily attempted, to the detriment of all concerned. The remedy is, "let the superintendent be a physician of high medical attainments, skilled in the practice of medicine, and then specially qualified in nervous and mental diseases." Let him devote his whole time to the cure and treatment of his patients, just as the general practitioner does to his. Let him have absolutely nothing to do with the ordinary business and administrative affairs of the institution, but let these be entrusted to the proper officers, who shall report to the executive board. The minor details of management and organization would follow in their proper order.

Assistant physicians should be selected from those who have paid especial attention to nervous diseases, and have taken a special course on insanity. As medical colleges, as a rule, have not established chairs of didactic and clinical psychiatry, the assistant physicians should receive sufficient instruction and assistance from the superintendent upon diagnosis, clinical history and treatment, so that they be not left unaided in the treatment of a disease most obscure to them; unless they receive such instructions, their entire course will be but one of guesswork and empiricism. In some institutions, each assistant has charge of from 200 to 300 patients, and sometimes has their exclusive medical care. "There should be at least one such officer to 100 patients in the State hospitals, where, it must not be forgotten, the great majority of inmates are incurable and need no special medical care. In other, or private asylums, where many recent and curable cases are received, this ratio should be much increased.

Consulting medical staffs are of great assistance to the medical officers, and to the patients, if properly appointed and conducted. Two alienists, a surgeon, a gynecologist, and a general practitioner would constitute a proper board, which should be an active, and not a mere dress-parade one.

As many asylums are now conducted, the strictly medical therapeutics of insanity is much neglected, and a routine both in prescribing and dispensing prevails. More attention and study of this subject are required by asylum physicians. Pathological work should also be carried on; the failure to do so in most hospitals is a natural consequence of the imperfections of the system and the inexperience of superintendents in pathological investigation.

Gynecological treatment is too much neglected in asylums. The wards are often greatly overcrowded and poorly ventilated.

The employment of patients is one of the problems of hospital management, and when intelligently and humanely carried on, it is a valuable adjunct to the treatment.

In order to prevent charges of unjust commitments, which are generally groundless, it should be required of the medical officers of hospitals that they render to some lunacy or other board their opinion as to the sanity or insanity of all patients, within one week after admission, this opinion to be based upon a careful examination in each case. With regard to prolonged detentions, they would be less liable to occur if patients were seen every day, and their cases carefully studied. "Owing to the failure of superintendents to give their personal and frequent attention to the inmates, I am satisfied that many restored persons are detained unnecessarily long, and others, through the importuning of relatives, are discharged before they ought to be."

Restraint is too frequently employed in our asylums; and on account of the facility with which it is abused it should be abolished altogether from hospitals in this country, as it has been in England and Scotland. Cruelties by attendants are more frequent than acknowledged by medical officers, or visiting managers; such offenses should meet with exemplary punishment.

With regard to the prevention of insanity, more knowledge is needed by the public, and especially the family physician, for under his care such incipient cases generally fall. Insanity in its forming stage may be easily cured; home treatment is to be preferred, if this is impracticable, then the case should be sent to a small private hospital or retreat, leaving the asylum as a last resort.

DR. R. J. LEVIS, of Philadelphia, then gave an account of some

SURGICAL EXPEDIENTS IN EMERGENCIES,

in which the skill and readiness of the surgeon are often severely tested. Some of these suggestions were quite ingenious.

In case of an *overdistended bladder*, where prompt relief is necessary and no catheter is at hand, he had taken a piece of bell-wire doubled upon itself so as to form a loop, which was readily passed along the urethral canal into the bladder. In a female a rye-straw might be used, its end being rounded with a little sealing-wax, or the stem of a clay-pipe, as crude substitutes for a catheter. In *phlebotomy*, when a proper lancet is not at hand, an ordinary pocket-knife will answer, provided the vein be held in position by transfixing it with a needle after applying the ordinary bandage.

For *obstinate epistaxis* requiring plugging of the nostril, a piece of sponge to which a string is fastened, is forced through the meatus to the posterior naris, small pieces of sponge are then to be threaded on this cord and pushed in succession into the passage until it is filled; when the danger of hemorrhage is over, they can be removed by reversing this process. Another good method in an emergency is to take a portion of the intestine of a chicken or other small animal, close

one end and pass it through the meatus; water or air may now be forced into the portion in the nostril so as to make equable compression. If it is necessary to plug the posterior nares, a slender gum bougie, or a piece of thick catgut ligature may be passed along the floor of the nostril and brought out under the soft palate; a string can then be attached and brought out of the nose in front by withdrawing the bougie, the sponge can then be employed in the usual manner.

In case of *bleeding from an intercostal artery* from a homicidal wound, he had succeeded in arresting the hemorrhage by introducing the upper part of an ordinary key into the pleural cavity, then turning it at a right angle, and making pressure upon the vessel. After this had been continued for some hours, the bleeding ceased.

A very efficient substitute for the *Esmarch elastic bandage*, is a flannel roller cut bias. For dislodging and forcing downward a *foreign body in the œsophagus*, an ordinary carriage or riding whip knotted sufficiently far from the end to ensure flexibility, may be used.

Good temporary *dressings for fractures* may be extemporized by tearing palm-leaf fans into strips; a more permanent fixed dressing can be made by dipping ordinary sand-paper in hot water, and applying it while soft, it adapts itself to the shape of the limb, but becomes sufficiently strong and rigid afterwards; hard dressings can also be made with starch, or eggs and flour.

In moving a patient with *fractured thigh*, the sound limb may be made into a splint, by fastening the legs together. In treating fractures of the femur, complicated apparatus is not necessary; simple extension by weights is all sufficient, the limb being kept in position by lateral supports or sand-bags. The postural method without splints is to be preferred in all fractures near to joints; fracture of clavicle is best treated by the supine position, with the head slightly elevated.

An ordinary gimlet is an efficient instrument with which to *open the mastoid cells* in case of abscess and threatening cerebral complication. The carpenter's rasp may sometimes replace the trephine in replacing fragments of bone after fracture of the skull.

A rubber tube may be used instead of a syringe in cases of *obstruction of the bowels*, the fluid being injected by hydrostatic pressure.

The substitution for belladonna of stramonium where a mydriatic is needed, and replacing carbolic acid by sulphurous acid, as a disinfectant; and the employment of hot water in place of all other styptics, were also mentioned. Dr. Levis prefers the straight glover's needle in place of the ordinary curved surgical needle for sutures.

DR. P. D. KEYSER, of Philadelphia, read a paper entitled

SOME OPHTHALMOLOGICAL OBSERVATIONS DURING TEN YEARS' SERVICE [1872–82] IN WILLS' EYE HOSPITAL.

In the affections of the lids, all the general forms of disease were more or less met with, and in the treatment of tarsal inflammation, many cases were much benefited by the use of De Wecker's pomade antiblepharitique, slightly modified as follows: Oleopalmitate of lead, 20 parts; almond oil, 10 parts; simple cerate, 5 parts; balsam of Peru, 1 part; liquid tar, ½ part. In most if not all cases of this affection met with, anomalies of refraction were found, the correction of which was necessary to succeed in a permanent cure.

In the treatment of conjunctivitis, weak solutions of astringents, instilled frequently into the eye, were found more efficient than strong solutions used once or twice daily. In purulent and gonorrhœal forms, reliance was placed upon frequent cleansing of the eye, and alternate instillation of saturated solution of boric acid and a weak solution of nitrate of silver.

Membranous conjunctivitis was treated successfully by a collyrium of chlorate of potash and hot applications, with quinine and iron internally.

Detachment of the retina was treated by several methods of operation, including that of De Wecker's drainage, and also by the use of pilocarpine internally and hypodermically, but without any great permanent success from either.

DR. JOSEPH HEARN, of Philadelphia, made some remarks on the

TREATMENT OF RODENT ULCER,

and exhibited three cases which he had had under treatment; one cured, the others greatly improved. In another case, which was not present, the disease had involved the eyeball and tissues around the orbit. The diseased eye was removed and the orbit cleaned out, the wound cicatrized; the patient is now well. One of the cases was a man in whom the disease had existed for six years, spreading over the right side of his head and destroying the auricle. He was operated upon two months ago by free scarification and caustics, and he is now getting well; the surface had almost healed. This case, it is believed, can be entirely cured. In the next case the disease likewise attacked the side of the head, and had existed for twenty years, for eighteen years he had had almost no treatment, but about two years ago he commenced to have pain, and the side of the face became paralyzed. The pain afterward became intense, and compelled him to apply for relief at the Jefferson College Clinic. The left auricle was then greatly deformed and almost destroyed. He was treated like the preceding one, and is now getting better. The third case is a woman, who had a patch of rodent ulcer upon her face; caustic was applied and she is now entirely cured.

Dr. Hearn claimed that if cases are properly treated they are readily cured, and even those where the disease had advanced so much as to be apparently hopeless, may get entirely well; but if a do-nothing treatment be pursued, the disease will steadily progress to a fatal issue. With regard to the character, it may be said to be non-malignant if properly treated, malignant if neglected.

Rodent ulcer usually begins as a nodule or papule in the skin, this is followed by a crust, which afterwards falls off leaving a raw surface surmounted by a swollen or papular border; it spreads by slow extension of this border. Unless proper treatment be instituted, it destroys everything down to the bones.

It is distinguished from simple ulcer by its mode of origin and slow course; and the rapid growth of syphilitic ulcers, and their multiple character, will easily enable them to be excluded. Syphilis occasions more destruction in a few months than rodent ulcer will in several years. From lupus, the diagnosis can be made positively only with the microscope; the border of rodent ulcer is composed of epithelial structure, that of lupus is infiltrated; the course of the two affections is also different.

The treatment of rodent ulcer is entire removal of the diseased tissue, by the knife or caustic.

The characteristics of rodent ulcer are, its slow growth, its occurrence in persons of advanced age—rarely earlier; though when it follows traumatism it may occur early; the patient from whom the eye was removed was only twenty-seven years of age, and it appeared first two years after the injury. In its growth it obliterates the capillaries and lymphatic vessels, and therefore does not infiltrate. The pain is slight, except when a nerve becomes involved. The lesion is usually solitary. In lupus, the growth is multiple. The man-

ner of extension is characteristic; one portion partially heals, while it spreads in another direction; one part cicatrizing, another progressing.

As to the treatment: when the disease is of large size, the knife must be used in connection with the caustic; the floor of the ulcer may be destroyed by caustic potassa, or hydrofluoric acid, or the Esmarch caustic. If the disease is near the bone, we must use the caustic. If the disease attack the eye, the orbit must be cleaned out and packed with the chloride of lime paste. In ordinary surface disease, he had seen the best results from caustic potassa. Usually, after the slough separates healing takes place, but occasionally one or two points will require additional application. Where patients refuse the knife, the caustic will sometimes answer equally as well as excision, if thoroughly applied. The potash is best used in a stick, and is to be especially used on the border.

In cases of so-called cicatrizing epithelioma, which are very similar to rodent ulcer, the ethylate of sodium has been highly recommended, applied with a brush or pledget of absorbent cotton; a thin slough separates, and cicatrization generally follows.

THE CARE OF THE HAIR.

DR. JOHN V. SHOEMAKER, of Philadelphia, read a paper on the use and care of the hair, in which the physiology of the hairy scalp was particularly considered, and the principles of hygiene in their application to treatment of the various capillary disorders especially insisted upon. The head-covering is considered responsible for early loss of hair, the stiff hats being especially condemned. After bathing, the hair should be thoroughly dried, and some unguent used; sea-water is injurious, if there is already a tendency to thinning of the hair; frequent cutting makes the hair coarse, and should not be permitted in young children, it also retards the growth of the hair; curling and crimping the hair are also condemned; hair tonics, dyes, and bleaching solutions of protoxide of hydrogen, are all injurious to the hair; depilatory applications should never be used.

Under the head of

UNFINISHED BUSINESS,

the Committee of Conference on the Schedule for

PRELIMINARY EXAMINATION OF STUDENTS

before engaging with a preceptor or commencing the study of medicine, recommended the following for adoption by the Society, in order that there may be uniformity in the Examining Boards of the several county medical societies:

SCHEDULE FOR EXAMINATION OF STUDENTS.

(1) Candidate's previous course of study; (2) An essay; (3) An essay written from dictation; (4) Spelling, oral and written; (5) Reading; (6) Geography; Political economy; (8) History, ancient and modern; (9) Geology; (10) Botany; (11) Chemistry; (12) Natural philosophy; (13) Mathematics, arithmetic complete, algebra through quadratic equations; geometry through plane geometry; (14) Languages—English, Latin, and Greek, the quantity of the latter to be at the discretion of the Examining Board.

This report lead to considerable discussion.

DR. JAMES TYSON, of Philadelphia, said that he was in favor of making an examination necessary prior to commencing the study of medicine, in order to ascertain if the candidate possesses sufficient preliminary education to enable him to engage in medical studies. It is necessary to adopt some practical method, but he thought the standard would be found to be not practicable. The colleges are anxious to adopt measures that will meet the views of the profession, but the requirements should not be too high at first. Three years ago the University of Pennsylvania adopted a qualification prior to matriculation, writing a simple essay in order to determine the spelling and writing process of the applicant; and, also, an oral examination in physics, such questions as how to change the degrees of Fahrenheit into Centigrade, etc. The result of this was, that the first year's class at once fell from 135 to 115, and the next year it was down to 98; the following year the reaction set in, and the Freshman Class went up to 115 again. The mere idea of a preliminary examination, kept incompetent men away, for only a few were rejected as utterly unfit, but many were conditioned. If we had sent away all who could not pass the examinations in physics the first year, we would have rejected half the class. The ultimate result has been beneficial; the members of the class are now of a much higher grade than before. For instance, of the 115, 35 had degrees in arts and sciences, about 30 more presented certificates from high schools and academies, the remaining 50 were examined, and of these not more than one-half were admitted after being conditioned on physics; each year we notice that a smaller number are conditioned, that is, a smaller proportion present themselves who are not educated. Now, this is a result of small beginnings. He was in favor of going to the full extent prescribed by the Committee, and to go to any extent recommended by this Society, but he believed that the carrying out of this schedule is impossible at present, and, therefore, if it is adopted, we would be obliged to go against the authority to which we look for advice and assistance. He said the University of Pennsylvania was desirous of raising the standard of requirements of preliminary education, and will gladly adopt any feasible method recommended by this Society.

DR. WHITCOMB asked how the Society would influence the colleges and county societies which refuse to carry out these rules?

DR. ULRICH defended the resolutions, as a step in advance, and recommended that students be sent only to colleges having advanced courses.

DR. S. D. GROSS asked how many students in the State of Pennsylvania could come up to those requirements? He said he was glad the schedule offered was not in existence when he commenced his medical studies as it might have effectually prevented them. He spoke in favor of the early study of practical anatomy by the student in preference to cramming him with books. He believed that a great injustice was often done to students by their preceptors in keeping them learning lessons by rote, when they should be acquiring knowledge in the post-mortem and dissecting rooms. The list of subjects presented is doubtless a good one, and men of the mental calibre of the committee could easily pass it, but many of the best practitioners of medicine and surgery never could. He thought the scheme impracticable and impolitic and hoped that the Society would not commit itself by its adoption.

DR. JACKSON called attention to the text of the schedule and said that there is not a high school in Pennsylvania which does not require this much from boys sixteen to eighteen years of age.

DR. BISHOP thought that the result of establishing a schedule of examinations like that proposed and making it obligatory, would be simply driving medical students out of Pennsylvania into other States that did not have such requirements. He thought it advisable to recommend the members not to take students at all, but send them directly to the colleges, where they could put in their time to better advantage. He hoped that the resolutions would be modified, so that instead of the examinations being compulsory they shall be advisory.

DR. DONNELLY recommended the adoption of the schedule, and thought that it should not be objected to by the colleges of Philadelphia. He could not see anything in the list that should meet with objection.

DR. UHLER thought that the remarks of Prof. Gross do not apply to students of the present day as they would to those of half a century ago. He believed that the colleges are not doing justice to any young man to allow him to begin the study of medicine, and after spending his money and time for two or three years, to turn around and say to him, you are not qualified to pursue the practice of the profession. This preliminary examination is only intended to prove to the young man that he is unfit before he spends his time and money.

DR. DE LONG said that if he had been told when he began the study of medicine what preliminary education was necessary, it would have saved him great trouble in acquiring it afterward, when he discovered the need. He thought that the greatest injustice was that he was not informed by his preceptor of his deficiencies when he commenced his studies.

DR. ALLIS reminded the members that this report is based upon resolutions adopted by the Society in 1878, by which such examinations are made compulsory. The action has stood before this Society for five years, and it is based upon recommendations of the American Medical Association. These examinations cannot be optional as long as those resolutions remain; they can be changed by action of the Society at any time.

DR. FINLEY, of Altoona, regretted that there was any discussion whatever upon the schedule; and was ashamed to learn that the colleges were in any way dependent upon the fees of young men who are not perfectly qualified for entering their studies. Over the medical colleges we have no control whatever. Ever since the establishment of the American Medical Association, and this Society, in 1848, not a single year has passed without pleas to the medical colleges for assistance in establishing a preliminary examination for students, but without the first spark of encouragement thus far. In answer to the objections which had been urged against this scheme, he referred to the Presidential Address before this Society, in 1850, of the late Dr. Samuel Jackson, a distinguished professor in the University of Pennsylvania, and to that of the illustrious Emeritus Professor of Surgery of Jefferson College, in 1883, before the American Medical Association, in both of which similar preliminary examination is most ably and earnestly advocated.

DR. S. D. GROSS said that he hoped that he would not be misunderstood. The ground he took many years ago he occupied to-day; he had never deviated a moment from the opinions he had then expressed. Where do our students come from? As a rule, from the offices of private preceptors, who send them unprepared to the colleges. He had spoken feelingly upon this subject a few moments ago, for he had himself spent eighteen months in the office of a high-toned, honorable gentleman, to whom he had paid two hundred dollars, and his time was misspent; he had great difficulty afterwards in making up, by great efforts, the time and money lost. All that he objected to is that the standard is placed at too high a point; and the only effect will be to drive students out of the State of Pennsylvania. It is of the first importance that the examiners inquire into a young man's moral character; he should be a gentleman by breeding and education; then a fair knowledge of his mother-tongue; some knowledge of Latin and Greek, but not too much. Let the standard be low. Of what use to the medical student is higher mathematics, geology, mineralogy, and botany? Who makes his own medicines at the present day? The time was when a knowledge of botany was essential; it is so no longer. If a man desires to study botany, let him do so; but, my word for it, he will not make much of a student of medicine.

A vote was then taken, and the resolutions and schedule were adopted.

On motion, two thousand copies of the report were ordered to be printed and sent one to each member of every county medical society in the State.

DR. R. L. SIBBETT, of Carlisle, read a lengthy report of the

COMMITTEE ON MEDICAL LEGISLATION,

giving a history of the Registration Act, and referring to its operation, and describing the difficulties in obtaining medical legislation. It recommended that efforts be now made to create a higher standard of public opinion upon medical topics, and, with this in view, urged the appointment of special committees to present papers before the annual meeting upon topics affecting the public health.

DR. E. A. WOOD, of Pittsburgh, said that registration is a failure. It simply lifts up the quack to the standing of the regular physician. He moved that the thanks of the Society be tendered the Committee for its labors, that the report be accepted, and the Committee discharged. Adopted.

TRAINED NURSES.

PROF. GROSS offered the following, which was also adopted:

Whereas, Good and well-trained nurses are of the utmost importance in every sick room, as a means of promoting the comfort of the patient and restoration to health; therefore

Resolved, That the physicians of every county represented in this Society, be requested to institute at suitable points, courses of instructions in the art and science of nursing, for such persons, male and female, who may be desirous of availing themselves of its benefits.

A resolution was offered by Dr. Curwen, that the President of the Society be requested to appoint a committee of three members on each of the following subjects: Medicine, surgery, diseases of women and children, insanity, idiocy, and ophthalmology. The duty of the committees shall be to prepare a series of questions calculated to obtain the history and treatment of the different forms of disease. It was adopted.

FRIDAY, MAY 11TH.—THIRD DAY.

MORNING SESSION.

After prayer by the REV. A. J. WEDDELL,

THE ADDRESS ON MENTAL DISORDERS

was delivered by DR. JOHN CURWEN, of Warren, and he choose for his special subject *Some Hints Toward the Prevention of Mental and Nervous Disorders*. He said no fact is more firmly fixed by physiological laws than that special physical conformations, peculiarities of manner, and modes of thought, which may inhere in any person, may be transmitted in full force and intensity to one or all of the children begotten by that person, and from the fact urged the necessity of a careful study of the life histories of individuals, in order to arrive at more exact knowledge in relation to the causes and conditions attending such cases, that thus more systematic efforts may be made for the prevention of mental and nervous disorders.

Reference was made to the impaired health of the mother during gestation as a frequent cause of mental and nervous disorders, and urged that special attention be given to the condition of the mother, to avoid, as far as may be, all sources of disease and various annoyances, to avoid these effects on the child. An

attentive study of individual cases would show wherein the connection might be traced, and thus by a careful collation of a large number of cases, some definite data could be obtained on which to found, or from which to formulate, some general directions for the conduct of such cases. Two opposite classes would require special care and management—the wives of farmers, mechanics, and laborers, who are compelled to do a large amount of household work, very often under trying circumstances giving rise to much anxiety and worry—and that class in the cities who spend their time in a round of gaiety and fashionable dissipation.

The profession should be more decided in their statements to those under their care in relation to many things which have an injurious influence on the health of the parents and their offspring, so as to prevent, as far as in their power, all such influences.

Special attention is called to the prime importance of the inculcation of habits of obedience in children, at the earliest age. The practice of sending children to school at an early age is deprecated, as tending to interfere with the proper physical development, and thus interfering with the proper training of the mental powers. Too much study in early childhood is deprecated, as tending to retard the development of the powers of the mind, and too many subjects of study at one time are objected to as likely to overtask the powers.

The necessity of ample and regular nutrition in childhood, youth, and mature years was strongly insisted on.

Regularity must be strictly observed in all the affairs of life; regularity in eating, regularity in exercise, in sleep, and in everything the individual is called upon to do, so as to maintain the due regularity which accompanies all the actions of the economy.

The importance of an ample amount of sleep at all periods of life was most especially insisted on, as no one thing was more likely to disorder the system than irregular and insufficient sleep. The amount of mental labor which can be borne with safety was dwelt on, and the fallacy exposed of requiring so much from growing children, whose brains were immature and in process of growth, and the danger pointed out of the ill-effects of such a course.

The character of the literature of the day was also spoken of as calculated to develop the passions and emotions to a much greater degree than the other powers, and thus with feeble intellectual training and a weak will, many were apt to become victims to morbid trains of thought and feeling, which led to mental disorders or some sudden termination of life in consonance with the books read. Such reading also leads to the indulgence of various secret habits, which have an effect in weakening the nervous system and placing the individual in such a condition as to be on the borderland between sanity and insanity, and thus in that morbid state which makes him the annoyance of the physician and the support of the irregular practitioner, who promises everything and does nothing to benefit the patient. The evil influence of tobacco on the young was also dwelt on, and the effect on the development of the mind pointed out.

MITRAL STENOSIS.

DR. J. T. ESKRIDGE, of Philadelphia, read a paper on the diagnosis, prognosis, and treatment of mitral stenosis. Of the two varieties of pre-systolic murmur, the vibratory or rough, and the bellows-like or soft, he agreed with Flint in the statement that the first is of much greater frequency than the second; indeed, he stated that he had never met with an instance of soft pre-systolic murmur. He had observed that mitral stenosis and mitral insufficiency were associated in about two-thirds of all the cases presenting the pre-systolic murmur, while Hayden (*Disease of Heart and Aorta*) believed that about one-half the mitral obstructive lesions are unattended by mitral regurgitation. With regard to the diagnosis of mitral stenosis, the pre-systolic murmur and purring thrill are the physical signs of most importance; the abruptness of the ending of the murmur in uncomplicated cases is especially noticeable, the bruit being best heard over the left ventricle, near the fourth cartilage, and is very rarely conveyed to the axilla or the back of the chest. In a feebly acting heart with this condition of mitral stenosis, the murmur may be temporarily, or even permanently, absent; on the other hand, according to Flint, a well-marked pre-systolic mitral murmur may exist without the presence of stenosis, but associated with aortic insufficiency. This, however, has been denied by Fagge and Balfour, and Dr. Eskridge could not confirm it from his own observations, but declared that he had never met with a case presenting this murmur in which mitral obstruction did not exist.

With reference to prognosis, the result will depend upon the extent of the lesion and the condition of associated organs, the coexistence of mitral regurgitation makes the prognosis more unfavorable.

In the treatment: 1. Rest in the recumbent posture. 2. Avoiding stimulants. 3. Protecting the surface from changes in temperature. 4. Local treatment by dry cupping, venesection, counter-irritants, and poultices may be used at discretion. For internal specific medication digitalis, when it agrees with the stomach, and is not contra-indicated otherwise; *Convallaria maialis* may also prove valuable, but he could not speak very favorably of it from personal experience.

DR. BOWEN, of Philadelphia, referred to two symptons, which are always present in mitral obstruction, even when murmur is absent. 1. Irregular rhythm, due to the difficulty in forcing the blood through the narrowed orifice into the ventricle, producing sometimes a double systolic impulse. 2. A valvular character of the first sound. This is very important in diagnosis, in the absence of murmur.

DR. ESKRIDGE attributed the absence of murmur in some cases to weakness of the cardiac muscle. In every case which he had seen early, there had been a murmur.

With regard to the first short sound, it sometimes occurs and sometimes does not. It is impossible in cases of atheroma and calcareous degeneration, where there are obstruction and regurgitation, the valves being too much ossified to be set in vibration by the blood.

Great irregularity of pulse also occurs late in the disease rather than early; irregularity is very unfrequent early in cases of mitral obstruction.

DR. WALKER, of Philadelphia, regarded it as impossible to diagnosticate mitral stenosis from simple roughening of the valves. A presystolic murmur of low pitch and course tone, when unassociated with mitral regurgitation and pulmonary symptoms, and irregularity of the heart, is of little moment; it may be considered as due to deformity of the valves. If the murmur is due to a button-hole opening, it will be high-pitched.

LITHÆMIA.

DR. JAMES B. WALKER read a communication upon lithæmia, which he said was a term applied to a diathesis, in which there exists a tendency to the undue production of uric or lithic acid, which, being less soluble and less readily eliminated than urea, sometimes accumulates until it is present in the blood in sufficient quantity to produce toxic effects.

It gives rise to a characteristic circulatory disorder by stimulating the muscles of the arterioles and causing their contraction. It retards the egress of the blood from

the arterial system, and thus leads to arterial hyperæmia. This calls for increased force of the left ventricle in emptying itself, and, through both agencies, we have developed the most characteristic symptoms of the lithic toxæmia, viz., *a pulse of high arterial tension.* The increased arterial recoil thus occasioned, so long as the aortic orifice remains impervious in diastole, causes an *accentuation of the aortic second sound.*

The increased arterial tension also occasions increased urination, the urine being high-colored and of a low specific gravity.

These constitute the prominent symptoms of toxæmia. But to them may be added others due to functional or organic disturbance of any organ of the body.

If treated early, when only functional disturbances have been engendered, it promises speedy relief. If organic changes have resulted, the organism is to that extent permanently crippled.

The *treatment* consists in

1. *Lessening the amount of nitrogenous detritus* by diminishing the amount of animal food. Meat must be used sparingly, though milk may be given freely. Vegetables should constitute a large proportion of the diet.

2. Bringing about as complete a combustion of the tissue waste as is possible, by bodily exercise and fresh air, in order that the uric acid may be converted into urea.

3. *Rendering more soluble and more readily excreted the uric acid which remains.* Lithia and potassium form with uric acid its most soluble compounds. These may be given as citrates or acetates in sufficient quantity, and for a long period, without injurious effects.

4. *Antagonizing by physiological antidotes the more violent and severe symptoms.* For the nervous symptoms which are most frequently the cause of complaint, the bromide of potassium is perhaps the most serviceable. For the angina pectoris, which is due to general vaso-motor spasm, cardiac as well as systemic, and which constitutes, when present, a most alarming symptom, amyl nitrite is the remedy *par excellence.*

For the complex symptoms likely to arise, appropriate treatment is demanded; but the lithæmia must not be overlooked in any one.

Dr. E. T. Bruen, of Philadelphia, spoke of the possibility of impacted renal calculus in lithæmia as a cause of pain in the lumbar region, in cases where lithic acid has been found for a long time in the urine. There is no great alteration in the urine, and certainly no albumen to indicate it, but only the obscure pain to suggest it. It can only be diagnosticated from all other causes of pain in the back by exclusion. He referred to two such cases, seen with Dr. Tyson, and mentioned this merely to refer to a possible cause of pain in the back.

Dr. Wood, of Pittsburg, said that the vibratile pulse which occurs commonly in lithæmia, can be relieved by suppositories of extract of opium and belladonna.

In a paper on the

CLINICAL USE OF CONVALLARIA MAIALIS,

Dr. E. T. Bruen, of Philadelphia, reviewed the physiological action of the drug, and illustrated clinically the employment of the drug.

He said he had found convallaria serviceable in those cases of acute disease of the lungs in which irregularity of the heart is a symptom. In these cases, the action of convallaria is helped by its combination with digitalis, the latter drug having a principal influence as a tonic to the cardiac muscle, the convallaria apparently exercising a principal influence on the vagi, or at least it inhibits the cardiac rhythm.

In organic valvular disease convallaria is most useful in cases of mitral obstruction. In these, the action of the heart is likely to be irregular, because the volume of blood returned to the left heart through the left pulmonary circulation has not time enough to empty itself through the left auriculo-ventricular opening. Relief of pulmonary congestion is the most constant indication for treatment. This has been met by venesection, by cups, by rest, by digitalis, but since digitalis is more of a tonic to the cardiac muscle than a stimulant to the vagi, we often find its use unsatisfactory. The indication is to slow the rhythm of the heart, and thus permit the right heart and left ventricle to empty themselves into the left ventricle, *afterward* it becomes needful to administer cardiac stimulants.

Irregular heart, as a symptom of mitral regurgitation, has been less positively benefited, since in these cases cardiac irregularity is a symptom of cardiac fatty degeneration. In mitral obstruction irregularity is an initial symptom.

Convallaria loses its effectiveness in valvular heart disease in proportion to the amount of fatty degeneration of the heart. Assuming as proven that the vagi are stimulated by digitalis, and that the reduction in number of the cardiac pulsations when digitalis is exhibited is due to this stimulation, it has been commonly found that when there is advanced fatty change in the heart the inhibitory effects of digitalis are less perfect, since there is less muscle through which the vagi could assert their influence. Moreover, in fatty heart a more powerful cardiac stimulant, such as digitalis, is required, and not a regulator. In advanced valvular heart disease, or cardiac failure in the catarrhal nephritic forms of Bright's disease, convallaria has not proven more useful than digitalis.

The drug is, however, of great service in cases where palpitation and dyspnœa rather than deficient cardiac systole are the prominent features. Broadly speaking, cases of phthisis or asthma in which palpitation and dyspnœa are prominent symptoms before cardiac failure from advanced fatty change ensues, are much benefited by this drug.

Its effect is often brilliant in purely functional heart disorder, especially palpitation and irregular cardiac action dependent on general debility. Also in cases of anæmia or hysteria, and to remedy the irregular action of the heart caused by tobacco.

In conclusion, it is proper to state that the preparation employed has been the fluid extract (Parke, Davis, & Co.). The doses fifteen or twenty drops, given every three hours in adults until the desired effects have been produced. Smaller doses have proven entirely negative. The drug is by no means a substitute for digitalis, which combines the properties of a cardiac tonic and regulator to a greater degree than any one drug in our pharmacopœia.

Dr. Musser, of Philadelphia, said that he had used convallaria in thirty cases of organic and functional diseases of the heart; about two-thirds of the cases were benefited, one-third were not benefited. With regard to the question of dropsy, the diuretic action of the drug was especially noticed where this symptom was present, but in three cases no relief was noticed; in two of these digitalis had also failed to give relief. The drug gave most benefit in mitral regurgitation; it is of little use in mitral stenosis. In combined aortic and mitral disease, it had given satisfactory results after the failure of digitalis. In cases of functional disorder of the heart, its effect was less evident. In one case of cardiac asthma it gave decided benefit; the heart slowed and became more regular in a short time, the pulse became stronger and fuller. Although the cardiac symptoms were relieved, the dyspnœa was not, contrary to the usual representations about the drug. In no case had he noticed any relief from dyspnœa.

The usual dose was fifteen to thirty drops of fluid extract, where it failed the doses had been too large; smaller doses should be given at first. There is no instance of cumulative action; the only disagreeable symptoms noticed were headache and dimness of vision in one case. The long use of the drug did not seem to give rise to any worse consequences than these; it appears free from dangerous effects. It seems principally to regulate the rhythm of the heart, at the same time increasing arterial tension, and the fulness and strength of the pulse.

DR. LEFFMANN presented, on behalf of the Philadelphia County Medical Society, the following

AMENDMENT TO THE BY-LAWS:

Resolved, That no paper shall be read before this Society, unless the same shall have been read beforehand, either in full or abstract, before a county society.

The hour of eleven having arrived, the Association went on a tour of

INSPECTION OF THE INSANE ASYLUM NEAR NORRISTOWN.

Mr. May, on behalf of the Board of Trustees, welcomed the Society, and spoke of the prominent features of the hospital; these are (1) relieving the medical superintendent of all domestic and administrative cares, outside of the medical care of the patients; (2) having a female physician in charge of the women; (3) non-restraint.

AFTERNOON SESSION.

The PRESIDENT called the meeting to order at 2 o'clock, in the chapel of the hospital. He announced the appointment of the committees.

DR. M. LANDESBERG, of Philadelphia, read a paper entitled

STRETCHING THE OPTIC NERVE,

in which he stated that he had performed the operation twenty-one times in thirteen patients. Sixteen times it was performed in the following manner: The conjunctiva was incised at the insertion of the internal muscle, which was then secured by a silk ligature. He then dissected up the internal muscle, and loosened Tenon's capsule and the underlying tissue down to the optic nerve: he then grasped the latter with a strabismus-hook, and stretched it gently three or four times. He then reattached the internal muscle by sutures, and applied a compressive bandage for a couple of days.

In five instances, the operation was performed without tenotomy, by making a slit in the lower and outer part of the conjunctiva, near the corneal margin, and passing a strabismus-hook between the external and inferior muscles down to the optic nerve. No bad consequences followed in any instance.

DR. W. S. LITTLE read a paper on

THE POSSIBILITY OF ABNORMAL OCULAR CONDITIONS, THROUGH THE SYMPATHETIC SYSTEM IMPAIRING THE FUNCTION OF THE UTERUS.

He reviewed the influence which disease of the uterus and its appendages has upon the eye, beginning at puberty and continuing to the menopause; both in the non-pregnant and pregnant state, as has been described by Prof. Förster, of Breslau, under the head of "Hysteria Kopiopia," and been fully corroborated by many observers, and more recently mentioned in Dr. Long Fox's Bradshaw Lecture, in which he related the influence of irritation from the hypogastric flexure, affords the most striking illustration, producing widespread and distant effects.

He next spoke of the influence of the eye, when the seat of irritation from unnecessary effort in seeing, upon the nervous system and some organs of the body, to which attention was called some years since by Drs. S. Weir Mitchell, and Wm. Thomson.

Dr. Little then traced the possibility of reflex irritation, as produced from a marked optical defect, differing in each eye, extending as far as the uterus, and impairing its function; regions more approximate, and other organs near the eye being markedly affected as well.

In the case in question, a married lady, thirty-four years of age, was seen in February, 1881, suffering from severe headache, pain in eyes, pain down region of neck, gastric disturbance, and marked hysteria. Examination of her eyes revealed a difference of refraction in each, one being hypermetropic, with hypermetropic astigmatism, and the other having hypermetropic astigmatism.

Relief from nearly all the symptoms rapidly followed the correction of the optical defect. At the time of treatment, no recognition was made of uterine trouble, or impaired function.

It was not till a year and a half afterward, she being in the mean time well, that I learned she had given birth to a female child, twelve years having elapsed since previous pregnancy, and the present being the second. There had been no miscarriages. The fact of this pregnancy having occurred so soon after the relief of her other troubles, which had persisted so long, and been relieved by correction of her optical defect, has drawn my attention to the influence that had existed, and reacted as far as the uterus and impaired its function.

In a paper on the

HYGIENIC MANAGEMENT OF CONSUMPTION,

DR. J. M. ANDERS, of Philadelphia, spoke very highly of the usefulness of house-plants and flowers in the sick-room, and as having positive therapeutic value in consumption. His researches had established the following facts:

1. That plants exhale aqueous vapor with great rapidity, at a rate of one and a quarter ounce by weight per square foot of leaf surface for twelve diurnal hours.

2. Through this process of transpiration they have the power to increase the humidity of the atmosphere of an apartment to any degree desired, by simply regulating the amount of leaf surface.

3. That the vapor emitted by plants is charged with some organic matter in passing through the plant, which may have peculiar sanitary value.

4. Recent experiments by the writer render it highly probable that flowering plants have the power of generating and emitting ozone.

A number of cases tending to show the value of plants as preventive and remedial agents in phthisis, are referred to, and other suggestive facts were communicated which render it strongly probable that the atmosphere of a room may be decidedly changed for the better for consumptives by the cultivation of house-plants with extensive leaf surface.

DR. ULRICH offered the following:

Resolved, That the Medical Society of the State of Pennsylvania desires to express its hearty appreciation of the kind hospitality and the reception extended to it by the Managers and the Medical Staff of the Norristown Hospital for the Insane.

Resolved, That the appointments of the Institution and admirable order prevailing, and absolute attention to cleanliness apparent in every department, have impressed us most favorably.

Resolved, That in the preparation for pathological and laboratory work, we see a promise of future scien-

tific work, which cannot but throw light upon the difficult subject of cerebral disease.

These resolutions were carried unanimously.

DR. LEE offered the following, which were likewise adopted.

Resolved, That this Society having listened to the numerous able papers upon the proper care of the insane which have been read during the present session, in which this important question has been discussed from every possible stand-point with the utmost freedom of expression, and in a truly scientific spirit, considers the following conclusions justifiable:

1. The problems connected with this subject, which in so intricate a manner interweave themselves on the one hand with the most sacred social and domestic interests of life, and on the other hand call for executive ability of the highest order, and scientific attainments of no mean value, that only those who have made them the subject of careful and conscientious study are competent to attempt their solution or to criticise those who are endeavoring to work them out.

2. That the attempt to create an impression that the incarceration of sane persons in institutions for the insane from improper motives is one of the dangers of the day, and an unworthy aspersion upon our profession, and should be frowned down by all reasonable persons, whether lay or professional, as utterly unsupported by evidence.

3. That in the medical superintendents of our insane hospitals and their assistants, physicians of both sexes, we recognize a body of workers second to none in our profession in unselfish devotion to the interests of humanity in elevation of motive, and high standard of personal character and general attainments.

4. That it is evident that in order to place such institutions throughout our country in a position to properly fulfil their functions as hospitals, in the treatment and care of diseases of the brain, our State Legislature must be made to feel an interest in making such appropriations as shall greatly increase their medical staff, and furnish them with all the necessary appliances for the investigation of disease.

The President announced the following appointments of readers of

ADDRESSES IN 1884:

Medicine.—DR. W. H. DALY, of Pittsburg.

Surgery.—DR. JOHN B. ROBERTS, of Philadelphia.

Obstetrics.—DR. JACOB PRICE, of West Chester.

Hygiene and State Medicine.—DR. JOHN G. LEE, of Philadelphia.

Mental Disorders.—DR. ALICE BENNETT, of Norristown.

Ophthalmology in its Relation to General Medicine.—DR. WM. S. LITTLE, of Philadelphia.

A cordial note of thanks to the Montgomery County Medical Society and to the citizens of Norristown, for their hospitality, was adopted.

Drs. Gallaher and Pursell, were appointed a committee to conduct the newly elected President, Dr. Henry H. Smith, of Philadelphia, to the Chair.

The President-elect then made a brief address of thanks for the unexpected honor conferred upon him by the Society.

A vote of thanks was given to the retiring President, Dr. Varian, and the Society then adjourned.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, April 24, 1883.

THE PRESIDENT, T. M. MARKOE, M.D., IN THE CHAIR.

LYMPHANGIOMA OF THE SKIN.

DR. F. LANGE presented a patient, a girl, thirteen years of age, whom he first saw about three months ago. When three years old, the mother first noticed in the axillary region a spot about the size of a silver quarter of a dollar, which had a reddish color. Since that time the spot has slowly but gradually increased in size, and during the last year it has grown quite rapidly. When Dr. Lange first saw the patient, there was quite an extensive growth in the axilla, consisting of an elevation of tissue somewhat the shape of a horseshoe, with some irregular attachments, and on the whole presenting an appearance not unlike condylomata. The excrescence-like growth occupied a space about five or six inches in length, varying from half an inch to an inch in width, and from a half to three-quarters of an inch in height. Besides this more massy growth, there were quite a number of small whitish vesicles spread over the skin in the neighborhood, apparently containing fluid; and when the entire growth was examined very carefully, it was evident that the more prominent parts were made up of an agglomeration of these small vesicles, forming an apparently papillary growth, and between these, numerous large bloodvessels could be seen. Dr. Lange excised the upper part of this tumor, leaving behind, however, a number of these disseminated, small, whitish vesicles, because he thought that the wound would be too large if all the skin on which these vesicles were situated was removed. Besides, he hoped to obliterate these isolated points by some other method of treatment. The operation was performed eleven weeks ago. A wound almost the size of the hand was left, but it had healed comparatively smooth, suppuration occurring only in a few places. About four weeks ago he noticed that in the scar these little whitish vesicles had reappeared, and they could be distinctly seen on close inspection, and when punctured with a needle a clear fluid could be pressed out. The actual cautery had been applied once upon the disseminated vesicles, but in the scars vesicles had reappeared. At present, he advised the local application of the strong tincture of iodine. The growth was located exclusively in the cutis. In the deeper parts of the skin there was at one point a thick mass which looked not unlike elephantiasis. The bloodvessels were so much developed that it was necessary to apply quite a number of ligatures at the time of the operation.

He had noticed that Caposi, in his recent work, mentioned only one case that he had seen. Dr. Lange thought that the vesicles were due to distention of the lymphatic spaces, and believed that the vesicles on the cicatrix were due to the same change. He had operated in one other case, that of a small child, who had a similar growth upon the side of the thorax. In that case, the subcutaneous tissue was somewhat involved. He had also seen another case, which was operated upon by Professor Esmarch. In both of these cases, however, the skin was not involved to such an extent, and complete extirpation in healthy parts could be performed with lasting success.

ABSORPTION OF ZINC FROM THE LOCAL USE OF A SOLUTION OF CHLORIDE OF ZINC IN THE TREATMENT OF A BURN; NEPHRITIS.

DR. L. A. STIMSON presented mounted microscopic specimens of the kidney, which, together with the history, were furnished by Dr. W. L. Wardwell, House Surgeon at Bellevue Hospital. Robert W., aged four years, a quadroon, of feeble constitution, was admitted to Ward I., Bellevue Hospital, January 2, 1883, suffering from a scald of the back and side, which included the left side of the back to within one inch of the median line, extending from the third dorsal vertebra above to the second lumbar below, the left side of the chest, and the left anterior surface of the abdomen, the left axilla, and the lateral abdominal region below

it; it extended down upon the anterior surface of the left thigh for three inches, and over the left acromion and lower part of the posterior surface of the neck. The scald differed in severity in its several localities upon the thigh and over the shoulder, and for the space of two inches at its edges only the epidermis was injured; in the axilla, just below it, and over the back, at the same level, the entire thickness of the integument was compromised.

Patient suffered at the time of the injury from shock, from which he reacted. The burns were dressed with carbolized vaseline spread upon strips of sheet lint; this being surrounded with cotton, and the whole secured by a bandage. The injured tissues sloughed extensively. The dressings were changed as often as necessary, and the patient's general condition carefully attended to. His temperature during this period fluctuated from 99° in the morning to 102° in the evening. On January 28, 1883, it was normal for the first time, it remained so for a few days; after that he rarely passed a day without an evening exacerbation of from one to two degrees. At the end of five weeks the sloughs had entirely separated, and the ulcer resulting was covered with small healthy granulations. During the following month the edges of the ulcer healed in very rapidly, and upon March 2d, two months after the injury, the original ulcer had diminished its dimensions one-half. During the next week the reparative forces appeared to be at a standstill, and during the two weeks following the newly formed cicatricial tissue broke down extensively, the ulcer regaining nearly its original dimensions. The patient complained of pain, and seemed to be relieved by frequent dressings. At these dressings the ulcer was sprinkled with a thin layer of iodoform, and then covered, as before, with sheet-lint spread with carbolized vaseline. About this time the urine was examined, as it had been when the patient first entered the hospital; no albumen or casts were found. Under this form of treatment no improvement took place, the appearance of the ulcer betokened a sluggish action; its edges were sloping and adherent, the lower portion was dotted with small islands of cicatrization, which had persisted while the surrounding tissue had broken down, the granulations were bluish in color, flabby, and did not bleed readily.

Upon April 4, 1883, the patient was etherized, the ulcer was washed with ℥iv of a five per cent. solution of chloride of zinc; there was no cavity or pocket in which any of the fluid could be retained. A dressing was applied consisting of three pads of *dry* carbolized gauze, each composed of six thicknesses of the gauze, these covered the ulcer only; over these was placed eight layers of gauge and one layer of mackintosh completely surrounding the body; the entire dressing was kept in place by numerous turns of a carbolized bandage. The patient vomited several times before the administration of the anæsthetic; this was attributed to some error in diet.

While reacting from the anæsthetic, patient vomited several times during the afternoon and evening. During April 5th, patient was either drowsy or sleeping most of the day; he appeared to be completely free from pain, and upon being questioned, replied that he felt well. His pulse was as good as before the dressing, and his changed behavior, which had been exceedingly irritable, and freedom from pain were subjects of congratulation, and were attributed to the good effects of the dressing; patient seemed to be easily nauseated and vomited several times. He was placed upon a milk diet, and bismuth was administered to check the vomiting. His temperature was, 10 A.M., 97½°; 10 P.M., 99°.

During April 6th, patient's general condition was much the same; his nausea persisted, but to a less extent. His temperature was, at 9 A.M., 97½°; 9 P.M., 99°. In the evening, the nurse reported, that patient had passed no urine for twelve hours; a poultice was placed over the abdomen, and pieces of ice put in the rectum; two hours later, he passed ℥iv of urine. This specimen was analyzed the following day, as follows: color, greenish-black; whitish sediment; specific grav. 1020; decidedly acid; albumen, one-third of bulk. Mr. Rice, the chemist at Bellevue Hospital, examined it chemically, and found that it contained *zinc* in a considerable amount. It was not tested for carbolic acid. During the twenty-four hours of April 7th, patient passed ℥iij of urine, of the same characteristics as that passed upon the 6th; a microscopical examination showed the presence of a few epithelial casts. Patient was placed upon the infusion of digitalis, and the region of the kidneys and bladder was poulticed. The pupils were not contracted. Temperature, 9 A.M., 98¼°; 6 P.M., 97½°; patient did not vomit but once; retained milk, ℥xvi, and a small amount of rice and milk.

April 8.—Patient passed ℥vss of urine, lighter in color than that passed before, but still decidedly greenish and containing a large number of casts of all varieties; he vomited several times during the day—otherwise his general condition was much the same—temperature, 9 A.M., 90°; 1 P.M., 101°; 5 P.M., 100°.

9th.—Patient complained that his back hurt him, and as the discharge had come through the dressing at several points, a new dressing was applied. As a result of the stimulation by the chloride of zinc, the character of the granulations had changed: they were decidedly more healthy and firm in appearance; the edges of the ulcer were making an effort at repair. At this dressing the surface of the ulcer was not disturbed by washing, and the *dry* pads of carbolized gauze were applied directly to its surface as before. After the dressing, patient was more comfortable. Temperature, 9 A.M., 98°; 5 P.M., 98°. He vomited several times during the twenty-four hours; he passed during the same period seven ounces of urine.

10th.—At 6.30 A.M., the house surgeon was called by the nurse, who reported that patient's temperature was 95⅕°. Patient was visited immediately. He was quiet; answered rationally; pulse rather more feeble than usual. He was surrounded with hot bottles, and given whiskey ℥j, with orders to the nurse to repeat the whiskey in fifteen minutes, and report in one-half hour if the temperature did not rise. Half an hour later the nurse reported that P. was still cold, and screaming with pain. The house surgeon immediately went to the ward, but, before reaching it, P. had died. The seven ounces of urine which P. had passed during April 9 were examined chemically for the presence of zinc: none was found. The color, which was darker than on the two days preceding, was found to be due to the presence of carbolic acid. Albumen was present in large amount, and casts of all varieties were more abundant than in any of the specimens previously examined. At no time during the course of the disease did P. show any signs of œdema, nor was he attacked by convulsions. A complete autopsy was not permitted. One kidney was obtained; weight, 4½ ounces. Capsule non-adherent; light in color; cortex swollen; stripings not distinct. Microscopically, the glomeruli are smaller than normal, either from pressure or contraction. Between them and the capsule there are decided spaces, which, in some instances, contain large cells, nucleated, suggestive of a glomerulo-nephritis. The cells lining the capsule are swollen and thickened, and, to a certain extent, desquamated. The capsules are thickened, probably the result of an œdema of the stroma. The convoluted

tubes are in many situations enormously dilated, showing probable fatty changes in the epithelium, and desquamation of the latter. A number of the tubes contain hyaline, epithelial and blood-casts, and some few pus-cells; but these are by no means frequent. Some of the tubes contain a detritus, which is suggestive of a preëxisting hæmoglobinuria, but this was not discovered during life. There are several foci of small-cell infiltration especially well marked in the vicinity of the bloodvessels.

Dr. L. A. Stimson presented a specimen which illustrated

BONE LESIONS OCCURRING AT A DISTANCE FROM A JOINT, BUT APPARENTLY PRODUCED BY ARTICULAR INFLAMMATION.

The specimen consisted of the lower portion of the femur and the upper portion of the tibia, removed by amputation from a man, who entered Bellevue Hospital on the 9th of April, 1883. He was thirty-two years of age, and stated that in October, 1881, he received a charge of buckshot just above the left knee; that five or six of the shot perforated the thigh from without inward, that two passed through the bone, four passed through the soft parts, and all but one made a complete passage through the limb; the sixth shot was cut out. He had been treated in various hospitals, and had undergone several operations, under ether, in some of which, so far as could be ascertained, bone was removed from the lower end of the femur; and the evidence remained of an incision having been made on the inner and outer sides of the thigh. Three weeks before admission to Bellevue Hospital, while in a city hospital, a phlegmon developed over the upper and inner portion of the tibia, on the same side. It was cut into by a straight incision, and the periosteum was found thickened, and exit was given to a small quantity of pus which was between the periosteum and the bone. At that time the man desired amputation, but it was not performed, and he left that hospital and came to Bellevue, and asked that his limb should be taken off. There were two openings, one on the outer and the other on the inner side of the thigh at its lower part, and a third opening made by the operation three weeks ago, over the upper part of the tibia. The probe could be passed completely through the thigh at its lower portion, but no bare bone was detected; bare bone, however, could be detected through the opening made over the tibia. Amputation was decided upon, and was performed by Dr. Wardwell, at a point about four inches above the joint. After the soft parts had been removed from the limb, the bones were sawn longitudinally, and presented the following appearances: The femur above the condyles was enlarged by subperiosteal thickening; about an inch and a half above the joint there was an opening in the bone which passed completely through from one side to the other, and its surfaces were covered with granulations to such an extent that bare bone could not be detected at any point; the knee-joint was completely obliterated by fibrous adhesions between the opposing articular surfaces, so that there was only a very slight amount of motion in it; the tibia at about an inch and a half below the articular surface showed a central abscess, situated immediately beneath the incision which was made in the periosteum three weeks previously, and before admission to Bellevue Hospital; it was separated from the external surface by an intact layer of compact bone. Two days before the operation the patient complained of soreness in this region, and the limb presented the signs of phlegmonous inflammation at a point corresponding to the tubercle of the tibia where the extensor muscles are attached, and here a small opening in the bone was found, leading into the abscess. In the head of the tibia there were two hemorrhagic foci, neither of which had suppurated. There was a third hemorrhagic focus below the abscess first mentioned. The patient, thus far, was doing well.

NEWS ITEMS.

NEW ORLEANS.

(*From our Special Correspondent.*)

The Smallpox Mortality for the week ending May 5th has fallen from forty-five in the preceding week, to thirty-four—fourteen white and twenty colored.

MONTREAL.

(*From our Special Correspondent.*)

Laval Question.—There are no further developments in the Laval question; whether or not, the old French school can maintain its independence, is still doubtful. There are rumors of an affiliation with St. Joseph's, a Catholic university in Ottawa. Though the decree from Rome has been accepted without discussion, we hear that the murmurs, though not loud, are deep, and that a very strong feeling exists against the interference of the clergy in matters pertaining to medical education. But in this province, with the church, means success; against it, ruin.

BERLIN.

(*From our Special Correspondent.*)

Prof. v. Bergmann.—There is a very lively period now in our medical world. To begin with surgery, we have to congratulate ourselves on the new acquisition made by the appointment of Professor v. Bergmann from Würzburg, as a teacher of clinical surgery in the University of Berlin. Born in the Russian Baltic provinces, and working many years as a professor at Dorpat, whence he made his name well known by his publications on "Sepsine," he reached the summit of his celebrity during the late Turko-Russian War, demonstrating then, for the first time, the applicability and the excellent results of Listerism in field practice, and saving the lives of many Russian soldiers with complicated fractures of the leg, or gunshot wounds of the knee-joint, by treating them antiseptically from the first moment. Since then, his reputation has rapidly grown. The University of Würzburg had enjoyed the benefit of his talents for but a few years, when the Berlin medical faculty offered him the chair made vacant by v. Langenbeck's resignation—a chair rendered illustrious not only by the names of v. Graefe (the uncle of the celebrated occulist) and Dieffenbach, but also by that of its last occupant.

Several recent publications of Prof. Bergmann—the last one on resection and suture of the intestines for the cure of artificial anus—give evidence that he does not intend to rest upon his laurels. Nor has he forgotten his former occupation as a field surgeon. In his capacity as surgeon-general of the Bavarian army, he has become an active member of the "Berliner militärärztliche Gesellschaft," where he delivered some lectures of great interest last winter. In the most important one, concerning the mechanism of gunshot fractures of the skull, Bergmann was able to show (by means of many preparations brought from the battle-fields near Plevna) that the influence of hydraulic pressure, although undeniable, has been highly overrated by some modern authors, the vast destruction of bone and brain being occasioned to a great extent by the particular shape of our modern musket-balls, which makes them liable to become deflected, thus causing

fractures of the bone and lesions of the brain in directions quite different from the original.

Hirsch's Historisch-Geographische Pathologie.—Prof. Hirsch has just finished the second volume of the new edition of his "*Historisch-geographische Pathologie.*" Here is an abstract of the table of contents: "Chronic infectious diseases (lepra arab., venereal diseases, yaws, button scurvy, verruga peruviana, endemic goitre, and cretinism); intoxications (ergotism, pellagra, pelade, milk-sickness, endemic colic); parasitic diseases (animal and vegetable parasites); infectious wound diseases (erysipelas, puerperal fever, hospital gangrene); chronic troubles of assimilation (chlorosis, anæmia intertropica, anæmia montana, scurvy, Beriberi, scrofulosis, diabetes, gout). A third volume will follow next year.

The New Code Controversy.—The Advisory Council of Physicians who support the New Code of Medical Ethics of the New York State Medical Society, met last Tuesday, at the residence of Dr. A. C. Post. Dr. Post presided. Drs. C. R. Agnew, D. B. St. John Roosa, F. R. Sturgis, H. G. Piffard, Joseph W. Howe, A. L. Loomis, F. A. Castle, and F. R. S. Drake, and Drs. Bailey and Snow, of Albany, were among the thirty physicians present.

The Committee on Canvassing reported a considerable accession of subscribers to the New Code.

Dr. Roosa presented a proposition from G. P. Putnam's Sons, for the publication of a book setting forth the main points in favor of the New Code, to counteract the influence of Dr. Austin Flint, Sr.'s, book in favor of the National Code, lately published. The proposition was accepted, and Dr. Roosa and the Committee on Intelligence were directed to prepare the volume.

The question then came up of the propriety of publishing some letters from some homœopathic physicians, designed to prove that certain prominent physicians of New York City, who are now earnest supporters of the National Code, have consulted with irregular practitioners. It was decided to publish them as campaign documents, with corroborative evidence.

Dr. J. W. Howe moved that a new canvass of the doctors of the State be made in order to ascertain their standing on the Code question. He said that many had pledged themselves for the National Code without due consideration, and many who had signed had since been converted to the New Code. It was decided to make a new canvass in the autumn.

Connecticut Medical Society.—The ninety-second annual convention of this Society, will be held in the City Hall, Hartford, next Wednesday and Thursday, under the presidency of Dr. Wm. G. Brownson.

Winnipeg Medico-chirurgical Society.—The physicians of Winnipeg have formed a medico-chirurgical society, with the following officers:

President.—Dr. Lynch.

Vice-Presidents.—Dr. Whitefield, Dr. Codd.

Secretary and Treasurer.—Dr. Covernton.

Commencement of College of Physicians and Surgeons.—The sixty-seventh annual commencement of the College of Physicians and Surgeons, of New York City, was held on May 15. Diplomas were awarded to 125 graduates. President Porter, of Yale College, delivered the address to the graduates. The Cartwright alumni prize ($500), was awarded to Dr. Walter Mendelson.

New Medical Journal.—The National Association for the Protection of the Insane and Prevention of Insanity has commenced the issue of a quarterly journal, which will be its official organ, under the title of *The American Psychological Journal.* It is edited by Joseph Parrish, M.D., of Burlington, N. J., and published by Messrs. P. Blakiston, Son & Co., of Philadelphia. The April number, Vol. i., No. 1, contains the papers read at the last meeting of the Association, held in Philadelphia, on January 25 and 26, 1883.

A New Edition of the British Pharmacopœia.—The General Medical Council have arranged for a new edition of the British Pharmacopœia, to be prepared under its direction by Profs. Redwood, Bentley, and Attfield, at a compensation of £800, this sum to include the cost of any experiments requiring to be made. The pharmacopœia committee recommend considerable changes in chemical nomenclature, in symbol notation, and in the method of representing the quantities of ingredients to be used in the preparation of medicines. They advise the addition of twenty-nine articles, and the omission of three.

Spanish Economy.—A Spanish magistrate, in view of the increasing adulteration of articles of diet, has issued the following proclamation: "All articles, in the shape of wines, groceries, and provisions, which, upon examination and analysis, are proved to be injurious to health, will be confiscated forthwith, and distributed to the different charitable institutions."

The Frontal Electric Photophore.—MM. Paul Helot and G. Trouvé, have completed an apparatus to be attached to the forehead, which furnishes a light derived from a pile of supersaturated bichromate of potash. It can be used for several hours at a time. The light is very intense, and can be used in operations about the mouth, ear, vagina, etc.

Pasteur's Pension.—The *Gazette Médicale* states "that it is expected that the Minister of Public Instruction will shortly lay before the Chambers a bill having for its object the increase of the annual pension voted by the Assembly to M. Pasteur from 12,000 fr. to 25,000 fr. This pension is to be reversible on the wife and children of the distinguished chemist. Without participating in all the opinions of M. Pasteur, and even while controverting some of them, no one will refuse his homage to the services which he has rendered to science, industry, and the public wealth; and everywhere, whether within Parliament or beyond its doors, approval will certainly be accorded to the expression of national gratitude which has led to this proposition."

Burial after Death from Contagious Diseases in Boston, Mass.—The Board of Health of the city of Boston, in pursuance of an Act recently passed relating to "The removal and transportation of certain bodies for burial," has issued a regulation, April 17, requiring that the bodies of all persons dying from smallpox, diphtheria, scarlet fever, typhus fever, or typhoid fever be immediately after death wrapped in a sheet saturated with a ten per cent. solution of chloride of zinc, and placed in a coffin, which must be made absolutely tight, and which must not be reopened. Undertakers and others having charge of the burial of bodies are instructed to comply with the regulation, and notify the Board of the compliance, whereupon will be issued the certificate which the law requires previous to the removal of the body.

HEALTH OF NEW HAVEN, CONN.—Dr. C. A. Lindsley, Health Officer of New Haven, in his report for the year 1882 to the Board of Health, gives the mortality for the year at 1343, which, estimating the population at 72,000, is equivalent to a death-rate of 18.65 per 1000. The average death-rate for the last fifteen years has been 19.06 per 1000 of the population. The rate has varied in different years from 16.73 to 21.90. In six of the fifteen years the death-rate was less than in 1882. Dr. Lindsley, commenting on these facts, suggests that captious critics might contend that the labors of the Board of Health have been fruitless, since the mortality of the past year differs so little from the average of so many years before. But, he insists, such criticism would be unjust to the Board. New Haven is not yet a large city, but it has for years been presenting with more and more distinctness the sanitary evils of class gradation in the social scale. It has more poor, and a steadily increasing number of the very poor. It does not present many illustrations of the squalid misery and wretchedness of a New York tenement-house, but it has too many and too close approximations to it. Nevertheless, the death-rate has not increased; and it is no insignificant achievement to prevent an increase of mortality in a large community undergoing the transition from the wholesome conditions of a rural town to the many unwholesome conditions of a city.

Dr. Lindsley argues that with the present knowledge of the laws of hygiene it is within the limits of reasonable demands that the City of New Haven should be put under such sanitary rule as would insure a reduction of the death-rate to 13 or 14 per 1000 yearly. To effect this the city must get rid of the vast amount of filth which is stored in the many thousands of cesspools and privy vaults honey-combing its site, and must prohibit its further accumulation. Authoritative control of the methods of house-drainage, including official supervision of all sewer connections is also needful. Nor is it considered too soon to provide legal restrictions respecting the erection of tenements in too close proximity, to dictate by law as to light and ventilation, to prohibit over-crowding, and the occupation of low, damp, and unhealthy basements, and to provide that the halls, staircases, hydrants, water-closets, privies, and such needful domestic arrangements, when designed for common use by many persons shall not be too limited in reference to the numbers using them; and that every precaution be taken for their constant care and cleanliness.

Efficient vaccination has protected the city from smallpox for several years back. There have been but fifteen deaths from this disease since, and including, the year 1873. The mortality from epidemic and contagious diseases during the year was exceedingly light; thus, there were but eleven deaths from scarlet fever, ten from measles, seventeen from whooping-cough, and twenty-four from typhoid fever. Croup and diphtheria occasioned sixty deaths, which number is slightly below the average for the previous ten years.

PROPOSED SEWERAGE FOR WILMINGTON, DELAWARE.—The Board of Health of this city (Dr. L. P. Bush, President), in its report for the year 1882, urges the disuse of the privy-pits and boxes which every year contribute more and more to the pollution of the whole substratum on which the city is built. For the disposal of sewage, the separate system is advocated, on the ground that it isolates all its contents from the general atmosphere; does not contaminate the soil; can be flushed and cleansed by properly adjusted, self-acting tanks, and, by proper plumbing, can be secured from the danger of infecting the dwellings of the people. The Delaware River is suggested as the outlet. Financial considerations are discussed thus: "There are 48,000 inhabitants in our city, which would give 9,000 families. A tax per annum of three dollars on each would amount to $27,000. The interest on $250,000 (the sum considered needful to cover the cost of construction) at four per cent. is $10,000, which would leave a balance of $17,000. Take $5 000 a year for repairs and supervision, and there would be $12,000 annually, which, applied to the reduction of the principal, would liquidate it in twenty years. after which a trifling sum would be sufficient to pay the expenses of the sewerage." The Board of Health called the attention of the City Council to the subject, and urges the propriety of memorializing the Legislature at its next session.

PLAGUE IN PERSIA.—The Sanitary Administration of the Ottoman Empire has received advices from Suleimania and Bagdad, dated April 14th, which state that one hundred and seventy deaths are reported as having been caused by the contagious epidemic which prevails in the villages of Zeitan and Bekir-beg, on the Persian frontier near the former city. It is characterized in every case by axillary and inguinal swellings. Quarantine measures are rigorously observed at the frontier and at Suleimania.

YELLOW FEVER IN RIO DE JANEIRO.—An epidemic has been prevailing in this city since the middle of March. During January, a few deaths were reported, but no apprehension was felt that the disease would spread as in 1880. In February, cases became more frequent. During the weeks ending February 3, 10, 17, and 24, the deaths reported numbered 5, 4, 5, and 13. In March, the advance of the disease became more rapid. During the weeks ending March 3, 10, 17, 24, and 31, the deaths were 24, 28, 41, 52, and 73. In the first week of April, 114 persons died, and in the second week 119, the total mortality from all causes during this week being 371. The shipping has remained comparatively free from the infection. One death was reported among the sailors on March 24, and another on April 14.

The figures given above do not include the deaths from the disease in the Santa Isabel Hospital; the reports from this hospital extend only to March 31.

	January.	February.	March.	Total.
Admitted,	7	96	365	468
Recovered,	...	15	182	197
Died,	6	43	122	171
Remaining,	1	39	100	100

FREEDOM OF THE BLACK RACE FROM DIPHTHERIA.—In summarizing the mortality statistics of Wilmington, Del., for the year 1882, Dr. L. P. Bush, President of the Board of Health, comments upon the facts that while thirteen deaths occurred from diphtheria among the white people, no fatal cases were recorded among the colored population. "This still further confirms the opinion of the freedom of the black race from diphtheria. This resistance of that class of people to the cause of this disease has been observed and recorded in the statistics of Wilmington since the disease made its first appearance among us in 1860."

We had the curiosity to look up the statistics of some of our Southern cities on this point, and found that during the year 1881 the District of Columbia lost 102 persons by diphtheria, 78 of whom were white and 24 colored people. The District, at that time, reported a population of 120,000 white and 60,000 colored. Norfolk, Va., with a population of 11,993 white and 10,033 colored, had 28 deaths among the former and 14 among the latter from the disease in question. Charleston, S. C., with a white population of 22,712

and a colored population of 27,287, had 15 and 10 deaths respectively. New Orleans had 69 deaths among its 158,379 whites and 11 among its 57,761 colored people. Memphis reported 21 deaths among its 18,622 whites, and 14 among its 14,971 colored population. Summing these figures, we find 211 deaths from diphtheria among 331,706 white, people and 73 deaths from the disease among 170,022 colored people. If the latter had suffered equally with the white race there should have been 109 deaths instead of 73. Although these figures show a greater mortality among the whites, they can hardly be said to sustain the idea suggested by Dr. Bush's comment.

Board of Health, Bayonne, France.—A municipal Commission of Hygiene and Statistics has been organized in Bayonne. Its constitution and duties are similar to those of the City of Paris. Very precise rules are laid down with regard to the medical inspection of schools.

Vital Statistics of Paris.—During the year 1882, there were 21,411 marriages celebrated in Paris, as follows: Between young men and maids, 17,579; between young men and widows, 1,206; between widowers and maids, 1,710: between widowers and widows, 904; between divorced persons, 12.

The births numbered 62,581, there being 31,828 males and 30,753 females, or 103.5 masculine births per 100 feminine.

The deaths numbered 58,702, the males being to the females as 116.1 to 100. The births were to the deaths as 106.6 to 100. Of the total number of deaths, 17,411 were of children under five years of age. Epidemic diseases were the cause of 7,579 of the deaths, typhoid fever being credited with 3,352, smallpox with 661, measles with 1,018, scarlet fever with 158, and diphtheria with as many as 2,390. Consumption was the cause given in 10,342 cases. There were 767 cases of suicide, 612 of the individuals being males and 155 females. The still-births registered amounted to 5,170.

Recent Mortality in European Capitals.—M. Motteroz, of the Bureau of Statistics, Paris, France, gives some interesting comparisons, formed in reviewing the mortality returns of the capitals of Europe for the first quarter of the present year. London, with its population of nearly four millions of inhabitants, shows the smallest death-rate—22.1 per 1,000 annually—and this although three epidemic diseases—measles. scarlet fever, and whooping-cough—occasioned a very considerable number of deaths during the period. St. Petersburgh, on the other hand, gives the highest mortality-rate—40.6 per 1,000 of its inhabitants yearly. Typhoid fever and diphtheria prevailed in this city with great intensity. Berlin gives a mortality-rate equal to 24.3 per 1,000 per annum. During the three months under review, croup caused 663 deaths in its population of 1,200,000. The rate of Brussels was 25.7; of Paris, 27.3; of Stockholm, 27.8; of Vienna, 31.1; and of Madrid, 36.4. The mortality in this last capital is always high. Measles, alone, was the cause of 402 deaths during the quarter, and this is regarded as an enormous mortality for a population of 400,000 inhabitants.

The Practice of Medicine in Missouri.—The General Assembly of Missouri has just passed a new law regulating the practice of medicine and surgery in that State, which contains the following provisions:

Every person practising medicine, if a graduate of a legally chartered medical institution in good standing, of whatever school of medicine, shall present his diploma to the State Board of Health, and upon its verification the Board shall issue its certificate, which shall be a license to practice; if not a graduate, the person practising shall be examined directly by the Board, and if found properly qualified, it shall grant a certificate to practice.

The Board shall furnish to county clerks of the several counties a list of all persons receiving certificates. If the diploma submitted be found to be genuine, the applicant shall pay to the Secretary of the Board a fee of one dollar, but if it be found to be fraudulent, or not lawfully owned by the possessor, the Board shall be entitled to collect twenty dollars from the applicant. Graduates may present their diplomas and accompanying affidavits by letter or proxy.

Every person holding a certificate from the Board shall have it recorded in the office of the county clerk of the county in which he resides, and the county clerks shall keep a register of certificates so recorded, which shall be open to public inspection.

The State Board may refuse certificates to individuals guilty of unprofessional or dishonorable conduct, and it may revoke certificates for like causes, after giving the accused an opportunity to be heard in his defence.

Any itinerant vendor of any drug, nostrum, ointment, or appliance of any kind intended for the treatment of disease or injury, or who shall, by writing or printing, or any other method, publicly profess to cure or treat diseases, injuries, or deformities by any drug, nostrum, manipulation, or other expedient, shall pay to the State a license of $100 per month, to be collected as all other licenses are now collected, and any person violating these provisions shall be deemed guilty of a misdemeanor, and upon conviction shall be punished by a fine not to exceed five hundred dollars, or by imprisonment in the county jail not to exceed six months, or by both.

Any person practising medicine or surgery in this State without complying with the provisions of this Act shall be deemed guilty of a misdemeanor, and punished by a fine of not less than $50, nor more than $500, or by imprisonment in the county jail for a period of not less than 30 days nor more than 365 days, or by both, for each and every offence; and any person filing or attempting to file as his own, the diploma or certificate of another, or a forged affidavit or identification, shall be guilty of a felony, and upon conviction shall be subject to such fine and imprisonment as are provided by the statutes for the crime of forgery in the second degree, but the penalties shall not be enforced until a period of six months after the passage of this bill. Provided, that the provisions of this Act shall not apply to those that have been practising medicine five years in this State.

Louisiana State Medical Society.—The fifth annual meeting of the Louisana State Medical Society was held in Shreveport, April 4, 5, and 6, 1883, under the presidency of A. A. Lyon, M.D., of Shreveport. Twenty-seven new members were elected. The President, for the Society, telegraphed a greeting to the Kentucky State Medical Society, and a pledge to stand by it in upholding the National Code of Ethics. The Kentucky Society responded, and endorsed the sentiment of allegiance to the National Code, and devotion to the honor and dignity of American medicine. The following officers were elected for the ensuing year: *President*, Dr. J. P. Davidson; *Vice-Presidents*, Drs. D. R. Fox, J. C. Bickham, C. M. Smith, F. J. Allen, I. J. Newton, and R. H. Day; *Corresponding Secretary*, S. S. Herrick, New Orleans; *Recording Secretary*, P. B. McCutchon; *Treasurer*, F. M. Parham. The next meeting of the Society will be held in Baton Rouge, on the 22d of May, 1884.

THE ANNUAL COMMENCEMENT OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF LOUISIANA was held in New Orleans on Thursday, March 29th. Diplomas were conferred upon seventy-four candidates. The class valedictory was delivered by Dr. Stanhope Jones.

GARMENT FOR PROTECTION AGAINST CONTAGION.—The National Health Society, London, has introduced a garment made of macintosh, to be worn by persons compelled to enter the apartments of persons suffering from contagious diseases. Used in connection with a medicated cotton respirator, it is said to be a protection against contagion.

HEALTH IN MICHIGAN.—Reports to the State Board of Health for the week ending May 5, 1883, indicate that diarrhœa, dysentery, and measles have increased, and that neuralgia, rheumatism, influenza, and consumption have decreased in area of prevalence.

Compared with the average for the month of April in the preceding six years, measles was considerably more prevalent, and intermittent fever, remittent fever, and diphtheria were less prevalent during the month of April 1883.

Including reports by regular observers and by others, diphtheria was reported present during the week ending May 5, and since, at seven places, scarlet fever at nineteen places, and measles at twenty-five places.

NOTES AND QUERIES.

IPECACUANHA AS AN OXYTOCIC.

To the Editor of THE MEDICAL NEWS.

SIR: The short assertion of Dr. Pitkin in THE MEDICAL NEWS of Feb. 3d, from *Journ. de Med. de Paris*, that ipecacuanha is an oxytocic, induces me to communicate my experience of the past week. During a case of tedious labor, primipara, I determined to administer Squibbs' fluid extract of ergot; by mistake, I took from my saddle-bags a vial of Squibbs' fluid extract of ipecacuanha; poured a teaspoon two-thirds or three-fourths full, and, in small quantity of water, had my patient drink it. Shortly afterwards, I discovered the mistake I had made, but did not administer any ergot, and concluded to await results, preparing myself for free emesis—none occurred; and, in the usual length of time, the uterus seemingly responded as vigorously to the ipecacuanha as I have ever had it to do to ergot. No vomiting took place until four or five hours after, when, on account of delayed third stage, I administered about thirty or forty minims of Squibbs' fluid extract of ergot, which was ejected almost as soon as swallowed, and vomiting occurred several times after. I do not claim that the ipecac had any effect upon the uterus—merely give you the *facts* of the case. Readers can draw their own conclusions: *Post aut Propter*.

Yours respectfully,
J. W. CANNON, M.D.

JACKSON, MO., April 30, 1883.

POISONING BY CHLORATE OF POTASSIUM.

To the Editor of THE MEDICAL NEWS.

SIR: The editorial on "Poisoning by Chlorate of Potassium," which appeared in THE MEDICAL NEWS of March 10, seemed to me to be very important. Few, if any, medicines enter so largely and generally into domestic drug supplies as chlorate of potassium. It is sold even in our confectionery stores, groceries, book stores, etc., in the form of candy, and its use is so very general that the amount of harm done by this preparation would almost equal the injury caused by opium. Few seem to understand its poisonous action, even in the medical profession, and anything which can be done to stay its wholesale use or abuse would be of great benefit to all concerned. The reaction which is now taking place, reminds me of the reaction against carbolic acid, bromide of potassium, and other drugs.

In throat affections it is most often prescribed, and especially so in diphtheria where absolutely no limit seems to exist for its exhibition. I have repeatedly noticed its injurious effects, and in one fatal case of diphtheria I attribute the result to too large doses of chlorate of potassium too often repeated. The patient seemed to be gaining rapidly until the *stomach gave out*, and in spite of every effort to control the irritability, vomiting persisted until death, which occurred thirty-six hours after this distressing symptom set in. I believe that the chlorate of potassium destroyed the tone of the stomach, and poisoned the whole system of the patient, and I confess I have never dared to use this remedy in diphtheria since then. We have a preparation of potassium chloride, very much used in Germany, which I like very much, and which I believe will soon be used in this country with great success. I am in the habit of prescribing it as follows:

℞.—Kali chlorici, ... ℥iv.
Aquæ destil., ... ℥vj.
Syr. simpl., ... ℥vj.—M.
S.—A teaspoonful or dessertspoonful every hour.

Whatever can be done to aid in sifting the good medicines from the bad, and guarding the public against poisonous dosing, is worthy of the serious concern of the medical profession.

Very respectfully, yours,
W. THORNTON PARKER, M.D.,
Act. Asst. Surgeon, U. S. A.

FORT ELLIOT, TEXAS, April 29, 1883.

EFFECT OF BROMIDE OF POTASSIUM ON CEREBRAL CONGESTION.

To the Editor of THE MEDICAL NEWS.

SIR: I notice in THE MEDICAL NEWS of April 21st, an article from Dr. Alban Kite, concerning the effects of bromide of potassium upon cerebral congestion following a dose of quinine. I would respectfully call the attention of Dr. Kite to the fact that the plan of using bromide of potassium, to prevent the unpleasant effects of quinine, is by no means new. In this portion of the South, where we "live among the fevers," and hence use a great deal of quinine, we have been in the habit for several years of either combining the bromide with quinine, or giving the quinine in hydrobromic acid, which I think is a preferable plan. I can heartily join Dr. Kite in saying that the bromide does frequently relieve the intense cerebral congestion produced sometimes by quinine, and I think it particularly adapted to children, but with them I should give hydrobromic acid the precedence. My friend Dr. Thomas M. Calley first used the bromide of potassium with quinine in Palestine, Texas, some years ago, and since that time we have all used quinine and bromide together, with considerable satisfaction. The combination is an excellent one, especially if the patient be of a nervous temperament.

Very truly yours,
J. WEBB DOUGLAS, M.D.

PALESTINE, TEXAS, April 30, 1883.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 7 TO MAY 14, 1883.

BARTHOLF, JOHN H., *Captain and Assistant Surgeon.*—The extension of leave of absence granted April 3, 1883, further extended four months.—*Par. 8, S. O. 105, A. G. O., May 7*, 1883.

BILLINGS, JOHN S., *Major and Surgeon.*—By direction of the Secretary of War, to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to be held at Cleveland, Ohio, June 5, 1883.—*Par. 10, S. O. 105, A. G. O., May 7*, 1883.

FORWOOD, WM. H., *Major and Surgeon.*—By direction of the Secretary of War, to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to be held at Cleveland, Ohio, June 5, 1883.—*Par. 10, S. O. 105, A. G. O., May 7*, 1883.

SMITH, JOS. R., *Major and Surgeon.*—By direction of the Secretary of War, to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to be held at Cleveland, Ohio, June 5, 1883.—*Par. 10, S. O. 105, A. G. O., May 7*, 1883.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

VOL. XLII. SATURDAY, MAY 26, 1883. NO. 21.

ORIGINAL ARTICLES.

BOROGLYCERIDE IN THE TREATMENT OF DISEASES OF THE EYE AND EAR.

BY L. WEBSTER FOX, M.D.,

OPHTHALMIC AND AURAL SURGEON TO THE GERMANTOWN HOSPITAL, PHILADELPHIA.

BOROGLYCERIDE, which has drawn the attention of surgeons to its antiseptic and astringent properties, has been used by me in the ophthalmological and aural department of the Germantown Hospital for the last six months. The number of cases treated have been numerous enough to justify my recommending it as a very valuable agent in the treatment of certain ocular and aural troubles.

To Dr. Granville Faught, formerly Resident Physician, I am greatly indebted for the successful preparation of the drug, as well as to his careful attention to the patients treated, and notes made on each respective case. I refer the reader to Dr. Faught's article on boroglyceride, in the present number of this journal, not only as to the manner of its preparation, but also to his views on the drug as a therapeutic remedy. Boroglyceride, when applied to the healthy conjunctiva, produces a sharp, smarting pain, lasting several minutes, profuse lachrymation and congestion of the smaller veins and arteries, not only of the mucous surface of the lids, but of the conjunctiva covering the eyeball; this being followed by contraction of the vessels, the sclerotic becoming pearly, and cornea particularly brilliant.

It has an acrid taste, not unpleasant. Its astringent properties are made manifest by a decided puckering of the mucous lining of the mouth.

In certain chronic conditions of the conjunctiva, patients do not complain of the smarting pain at first, but after several days' use this becomes manifest.

The preparations used have contained ten per cent., twenty-five per cent., and fifty per cent. of the drug in glycerine. It is soluble in glycerine, cold and hot water.

In cases of acute conjunctivitis, with slight secretions, the following collyrium has been efficacious.

℞.—Boroglyceride, ... ʒj.
Camphor or rose water,
Distilled water, ... āā ʒj.

This can be applied either by a bit of cotton-wool or by the spray. After several applications, the congestion disappears, and the mucous surface is restored to its normal condition. In granular lids, with much thickening of the conjunctiva complicated with pannus of the cornea, a fifty per cent. solution was used. The slight purulent secretions were checked immediately; the thickened and congested condition of the conjunctiva was reduced, the vessels on the cornea disappeared rapidly, leaving it clear and transparent; but no change is observable in the hypertrophied condition of the papillæ, excepting to make them more pronounced in their outline. At this stage of the treatment, xerosis conjunctivæ is not unfrequently produced. The conjunctivæ are free from moisture, and the patient has sensations of heat and dryness in the eyes, which are distressing. The treatment should be discontinued, and a solution of nitrate of silver, five or ten grains to the ounce, substituted; one application daily should be made to the parts, until the normal secretions are restored; then the sulphate of copper, in substance, is to be applied once daily to the now reduced trachoma. Under this treatment the granulations disappear very rapidly, the lids become smooth, and, where there is pannus, the cornea regains and retains its transparency.

One case of membranous conjunctivitis (pseudo-membranous conjunctivitis of Tweedy, see *Lancet*, of January 7, 1882), in a child of ten months, was brought to me. The lids were swollen and œdematous, the membrane could be taken off in shreds, the conjunctiva ecchymosed, and corneæ of a decided opaline tint. The disease was—according to the history given by the mother—only of twenty-four hours' standing. Cold dressings, with an application of boroglyceride—fifty per cent. solution—fifteen to twenty drops between the lids, gently raising them to allow the fluid to permeate the parts, were ordered; the iced dressings to be kept on the lids constantly, and the boroglyceride applied once every hour. The acute condition was soon allayed, no membrane forming after the fifth application of the drug. At the beginning of the third day, the case was treated with a ten per cent. solution; and at the end of a week the patient was discharged, cured.

In all catarrhal affections of the eye the drug is valuable, particularly so in ophthalmia neonatorum. It arrests the secretions, reduces the congestion and swelling, also disinfecting the parts, thereby changing the character of the pus from a whitish-yellow or a greenish-yellow to a serous discharge. In several cases, where the treatment was omitted for twenty-four hours, the discharge became purulent again. One case which had been treated by such domestic remedies as mother's milk, tea leaves, etc., for two weeks was in a deplorable condition when placed under my care. The cornea of the left eye was gone, the right in a stage of ramolissement. The patient recovered, a slight nebula marking the place in the right eye where the cornea had commenced breaking down, the left globe shrinking to the size of a pea. My assistant, Dr. Alexis I. Smith, has kindly placed at my disposal the notes of one of his cases of ophthalmia neonatorum treated in private. As his results have been confirmed by several colleagues to whom the boroglyceride was given, I quote Dr. Smith's case in full.

"On the 20th of January I was called to see T., æt. five weeks, with the following history: The mother said that two days after birth she noticed a purulent discharge from the baby's eyes, with great swelling of the lids; she thought the child had caught cold from a draughty window, and would get well by itself. She was attended during her labor by a neighbor, and had no physician. She had no leucorrhœa at the time of her confinement, nor at any time previous was there any discharge to her knowledge. When I saw the baby the eyelids were enormously swollen and closed, the edges encrusted with dry pus, and when the eyes were opened pus escaped freely. It was impossible to see the condition of the cornea, owing to the extreme swelling and the restlessness of the child. The infant was exceedingly emaciated, bottle-fed, and very constipated. I ordered the mother to put one drop of a fifty per cent. solution of boroglyceride in glycerine in each eye every four hours, to bathe the eye freely every hour with warm water, and give minute doses of calomel every hour until bowels were moved. The next day the discharge was very much diminished and the swelling somewhat so, but not enough to allow an examination of the cornea. On the following day, however, I saw that the corneæ were bright and clear, the swelling very considerably reduced, and the discharge, which was altered in character, having become more serous. On the fifth day the discharge was almost entirely absent during the day, being noticed most in the morning. The lids were anointed night and morning with cold cream, and after the third day the boroglyceride was ordered three times daily.

"As the child seemed to be doing well, I did not see it again for four days, when I found that, owing to my directions having been neglected and the treatment not having been carried out, the discharge had returned almost as bad as when I first saw it; insisted on having the eyes washed every hour. I ordered boroglyceride every three hours during the day. Being prevented by sickness from seeing the child for a week, at the end of that time I found the disease cured."

My treatment in severe cases is to apply five to ten drops of a fifty per cent. solution of the drug every hour, bathing the eyes first with tepid water to cleanse them properly; after a cessation of the discharge a weaker solution is used, or the stronger is applied at longer intervals. The eyelids may be anointed with vaseline at night."

Ulcers of the cornea. It has been observed long ago that phlyctenular ophthalmia is one of the most troublesome and intractable diseases that the ophthalmic surgeon has to deal with. The principal cause of the extreme tediousness of this disease is the strumous diathesis. In cases where this condition existed the local affection was slow to respond to the boroglyceride; but when the general system was improved, the eyes recovered rapidly.

In deep central ulcers of the cornea, which are always slow to respond to the usual remedies, the boroglyceride has proved one of the best remedies in my hands.

In vascular keratitis we have associated an inflammation of the conjunctiva. The sulphate of atropia, by dilating the pupil and paralyzing the ciliary muscle, checks, to a degree, the blood supply, acting also in many cases as an irritant to the already inflamed conjunctiva, also aggravating the primary lesion. To correct this and retain the atropia, I have combined it (grs. iv. to ℥j) with a fifty per cent. solution of boroglyceride, applying this combination thrice daily. The bloodvessels on the cornea disappear rapidly, and the patient is relieved of the distressing symptoms.

As a dressing for wounds in ophthalmic surgery boroglyceride is valuable, acting as an astringent, antiseptic, and deodorizer, thereby allaying inflammation, checking discharges, and keeping wounds sweet.

Four cases of cataract wounds were dressed with a twenty-five per cent. solution of boroglyceride, to which had been added sulphate of atropia, grs. iv.–℥j. Three cases made a perfect recovery, no unfavorable symptoms arising at any stage of the healing process. In the fourth case the result was negative. This patient was operated upon two years ago for cataract in the right eye; panophthalmitis followed, and the eye was lost. A preliminary iridectomy was performed at this time in the left eye. On the 4th of December, 1882, a successful modified Græfe's extraction was performed. Fingers were counted immediately after the operation. On the evening of the fourth day after the extraction some pain was felt by the patient. Slight swelling of the conjunctiva was noticed by Drs. Müller and Radcliff, who had had charge of the case. On examining the eye the following morning, a faint yellowish reflex was noticed in the vitreous. The wound had closed perfectly. Antiphlogistic remedies used—negative results followed. In this case the vitreous was the primary seat of inflammation, for at no time was there any discharge.

In diseases of the ear, the drug was limited to the treatment of purulent discharges, both acute and chronic. The results obtained were very satisfactory, particularly so in odorous discharges, as the offensive smell was dispelled after three applications. A fifty per cent. solution in glycerine was applied in the following manner: The secretions thoroughly removed by dry cotton; the patient's head placed in a horizontal position—when pain was present a few drops of tinct. opii and belladonna, equal parts, applied first—the meatus filled with the boroglyceride, and the orifice closed with cotton; this process repeated every six hours in acute cases, in chronic troubles every twelve hours. Good results were obtained in six to twelve days.

I may mention that my friend, Dr. Faught, has been successful in making gelatine disks for ophthalmic purposes, containing ten, twenty-five, and fifty per cent. of boroglyceride. In certain discs he has also succeeded in combining a myotic, mydriatics, and several of the astringents with the same. They dissolve readily in the secretions of the conjunctiva.

The results of our investigation as to the therapeutic value of boroglyceride in ophthalmic and aural diseases may be briefly summed up as follows:

In conjunctivitis, catarrhal affections of all kinds,

ophthalmic neonatorum, ulcers of the cornea and conjunctiva, and wounds, it has proved more effective than the usual remedies applied.

In blepharitis, granular lids, pannus, nebulæ, pinguecula, pterygium, and episcleritis, it is an adjuvant of great value.

1306 Walnut Street.

BOROGLYCERIDE.

By G. GRANVILLE FAUGHT, M.D.
of Philadelphia.

Boroglyceride, lately patented both in this country and Great Britain under the name of "Barff's Preserving Compound," is deserving of some attention from the medical profession as an antiseptic, and also on account of its astringent properties. Its inventor designs it as a preservative for meats, milk, and other food products, for which, from repeated trials, it seems well adapted. In medicine its use is as yet in its infancy, the literature of the subject being confined to a few scattered writings in English and Continental journals.

The present article is designed to merely call attention to the substance, the method of its preparation, and some of the uses to which it is specially applicable.

As its name implies, boroglyceride is a combination of boric acid and glycerine, the proportion being that of their atomic weights, thus:

Boric acid.		Glycerine.		Boroglyceride.		Water.
BO_3H_3	+	$C_3H_5(OH_3)$	=	$BO_3C_3H_5$	+	$(H_2O)_3$
62		92		100		54

The mixture of acid and glycerine is to be heated until the three parts of water are driven off. Especial care is to be taken to maintain the proper temperature, for if heated too highly the glycerine will decompose, while pungent fumes of *acrolein* will be given off, and the resultant will be dark colored and possess irritant properties. It is better to expel the water by gentle and long-continued heat than by boiling it violently.

Boroglyceride is a light-amber colored, vitreous substance, without odor. It is soluble in glycerine in all proportions, sparingly so in hot water (about ten per cent.). The taste is warm and somewhat astringent. The form in which I have been accustomed to use it has been a fifty per cent. solution in glycerine; a very viscid preparation.

During the last six months I have used it largely, both in hospital and private practice, as a local antiseptic astringent. I have never given it internally myself, but it is claimed by its inventor to be innocuous.

As a surgical dressing boroglyceride holds an important position, serving to allay inflammation, check excessive discharge and sloughing; it is a decided antiseptic, and acts as a deodorizer. Added to poultices (fifty per cent. solution) it serves to keep them moist and sweet for a long time; those who have had charge of a surgical ward during the summer months will know how desirable these points are. Using the fifty per cent. solution, conjoined with sponge-grafting, I have succeeded in healing several ulcers that had defied every other method of treatment.

As a vaginal application for leucorrhœa and subinflammatory conditions of the cervix, I have used either the cotton suppository, or, what is much better, the oakum suppository of Emmet. A piece of oakum of sufficient size is spread out, and on this about half an ounce of the fifty per cent. solution is poured; the oakum is then folded around it, and a string attached which enables the patient to remove it herself. Such a suppository will remain in the vagina, perfectly sweet and clean, for twenty-four hours. In this class of cases I have also used gelatine pessaries containing twenty-five to seventy-five per cent. pure boroglyceride. These may be inserted by the patient herself. The results obtained by this method of treatment are surprising; in a large number of cases the discharge is stopped by one application.

In specific urethritis in the male, a limited trial has given good results. I used gelatine bougies containing twenty-five to fifty per cent. of pure boroglyceride. These bougies are conveniently made by using a druggist's pill-board; after *slightly* greasing the two sets of grooves with cosmoline, they are covered with the hot solution of gelatine and boroglyceride, and then put together; when cold, the rods are easily removed, and can be united to form any length by gently warming their ends with a spirit-lamp. A single length would be suitable for introduction into the uterine cavity.

Dr. W. A. Jamieson (*Edinburgh Med. Journ.*, Dec. 1882) reports very satisfactory results from the treatment of diphtheritic sore-throat with boroglyceride. In the treatment of pharyngitis and tonsillitis, I have found it very satisfactory.

My thanks for the gelatine preparations are due Mr. C. H. Gubbins, Pharmacist, N. E. cor. 15th and Race Streets.

142 N. 15th Street.

MEDICAL PROGRESS.

Caffeine in Cardiac Affections. — Huchard, after reporting an interesting case of asystole cured by caffeine, gives a series of conclusions deduced from cases which he has studied. 1. In certain cases caffeine is superior to digitalis, on account of its rapid action, diuresis being almost produced in twelve or twenty-four hours. 2. If caffeine diuresis comes on rapidly, it rarely attains the proportion of digitaline diuresis, and does not exceed three or four quarts per diem. 3. Caffeine is superior to digitalis on account of its innocuous action, which results from its easy and rapid elimination. Cumulative and toxic effects are rare, as is gastric intolerance. 4. Caffeine only produces gastric intolerance when the liver is diseased, as in cirrhosis. 5. If digitalis produces bad effects, or is powerless in cases of fatty degeneration of the heart, caffeine will often be of great benefit. 6. It appears to be of no service in albuminuria of non-cardiac origin. 7. As a rule, caffeine is not given in sufficiently large doses; grs. iv–viij should be given at the beginning of the treatment, gradually increasing to grs. xij, and up to grs. xv, xxx, or even xlv. It should be taken three or four times during the day.

8. Though it has been used subcutaneously, it is doubtful if it is so efficacious when given in this manner as by the stomach.—*Revue des Sciences Méd.*, April, 1883.

A RAPID METHOD OF DEMONSTRATING THE TUBERCLE BACILLUS WITHOUT THE USE OF NITRIC ACID.—DR. HENEAGE GIBBES, in a paper on this subject, says: The following method, which I have used for some time with great success, will, I think, prove useful to those requiring the demonstration of the tubercle bacillus for diagnostic purposes in a rapid manner. The great advantage consists in doing away with the use of nitric acid. The stain is made as follows: Take of rosanilin hydrochloride two grammes, methyl blue one gramme; rub them up in a glass mortar. Then dissolve anilin oil 3 c.c. in rectified spirit 15 c.c.; add the spirit slowly to the stains until all is dissolved, then slowly add distilled water 15 c.c.; keep in a stoppered bottle. To use the stain: The sputum having been dried on the cover-glass in the usual manner, a few drops of the stain are poured into a test-tube and warmed; as soon as steam rises pour into a watch-glass, and place the cover-glass on the stain. Allow it to remain for four or five minutes, then wash in methylated spirit until no more color comes away; drain thoroughly and dry, either in the air or over a spirit-lamp. Mount in Canada balsam. The whole process, after the sputum is dried, need not take more than six or seven minutes. This process is also valuable for sections of tissue containing bacilli, as they can be doubly stained without the least trouble. I have not tried to do this against time, but have merely placed the sections in the stain and allowed them to remain for some hours, and then transferred them to methylated spirit, where they have been left as long as the color came out. In this way beautiful specimens have been made, without the shrinking which always occurs in the nitric acid process.—*Lancet*, May 5, 1883.

SUBCUTANEOUS INJECTIONS OF RESORCIN IN ERYSIPELAS.—BOGUSCH has employed resorcin hypodermatically in four cases of erysipelas, in the form of an aqueous solution, five per cent. The injections were made along the erysipelatous line at distances of about one-half inch apart, the needle being directed toward the diseased structures. In the four cases, 29, 36, 67, and 70 injections were made, no other agent being used. The results were a rapid fall of temperature and arrest of the disease.—*Revue des Sciences Médicales*, April, 1883.

RESECTION OF THE TARSUS.—DR. LAUENSTEIN, of Hamburg, exhibited a patient before the Twelfth Congress of the German Surgical Society, whose whole tarsus, with the exception of the astragalus and a portion of the calcaneum, he had resected. Two incisions were made, one on each side of the foot. The result was far better than could have been expected; the foot was a little less than one-half inch shorter and slightly smaller in circumference than the other. The limp in his gait was scarcely perceptible, and he could easily walk for one-half an hour. There was good reproduction of bone.—*Berliner klin. Wochenschr.*, April 23, 1883.

ADONIDINE.—This new product has been recently obtained by CERVELLO from the *Adonis vernalis*, a plant of the ranunculaceæ family. Cervello succeeded in extracting a glucoside from the plant containing the whole active principle, and to which he has given the name *Adonidine*. Adonidine, which is most easily obtained pure from the tannate of adonidine, is an amorphous, colorless, odorless mass, very bitter, very soluble in alcohol, less so in ether and water. It is precipitated from its solution by tannic acid, but redissolves on the addition of an acid. Brought in contact with an acid, a substance is produced which is soluble in ether. The physiological effects of adonidine are in all respects similar to those of digitaline, but much more energetic, gr. $\frac{1}{250}$ being sufficient to arrest the heart of a frog. From experiments on dogs, rabbits, and frogs, Cervello concludes that adonidine has no cumulative effects, and on this account is preferable, as a therapeutic agent, to digitaline.—*Revue des Sciences Méd.*, April, 1883.

THE CAUSE OF HYSTERICAL TYMPANITES.—EBSTEIN regards the tympanites which develops so rapidly in an hysterical attack, as due to an incontinence of the pyloric sphincter, and when air is swallowed during an attack it passes through the stomach directly into the intestines. He experimented upon two cases by giving an effervescing mixture, and found that the phenomenon was markedly increased immediately after it was swallowed. He regards this as a pathological condition; Küssmaul, however, asserts that when the stomach is empty, relaxation of the pylorus is the normal state.—*Centralbl. f. klin. Medicine*, March 31, 1883.

INJECTIONS OF IODINE IN MALIGNANT PUSTULE.—PROF. RICHET recommends the subcutaneous injection of tincture of iodine in malignant pustule. He has used as much as 100 to 120 drops at one injection, and insists that they do not produce bad effects in the patients, and have a powerful influence over the disease.—*Revue des Sciences*, April 21, 1883.

BLOOD-GLOBULES IN PURULENT PLEURISY. — The observations of GASEL confirm, in a measure, the existence of leucocytosis in cases of suppuration. He thinks that an enumeration of the globules is a valuable diagnostic sign in empyema. He takes, as a term of comparison, the results given by Graucher, that in the normal state the number of red globules is between five and six million per cubic centimetre; of the white, between three and nine thousand—the relation being $\frac{1}{1200}$ or $\frac{1}{1500}$. In four cases of empyema, the relation was $\frac{1}{309}$; $\frac{1}{390}$; $\frac{1}{264}$; and $\frac{1}{320}$.—*Revue des Sciences Méd.*, April, 1883.

NITROUS OXIDE AS AN ANÆSTHETIC.—M. PAUL BERT has recently read a note before the Academie des Sciences of Paris on the anæsthetic properties of nitrous oxide. The difficulties attending the production of anæsthesia with a mixture of nitrous oxide and air under certain barometric pressure, are well known. The pure gas anæsthetizes, but tends to produce asphyxia if prolonged for a certain time; mixed with oxygen it does not asphyxiate, but neither does it anæsthetize. In spite of the danger of asphyxia, there has been a ratio of only three or four accidents per thousand cases in which it has been used by dentists. It cannot, then, be considered as a dangerous substance. It should not be employed intermittingly, as has been done in America. Instead of using first pure nitrous oxide and then pure air, M. Bert uses a mixture of oxygen and nitrous oxide in proportions very similar to those of the air which we breathe. The experiments were made on dogs. The animal first respired pure nitrous oxide for a minute, then the mixture for five or six minutes, and so on until complete anæsthesia occurred, which was prolonged for half an hour without bad effects. He thinks that further experiments are needed before it should be used on man, though it would seem that the results would not be less satisfactory.—*Revue des Sciences*, May 5, 1883.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address, HENRY C. LEA'S SON & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA, PA.

SATURDAY, MAY 26, 1883.

SENILE GANGRENE.

SENILE gangrene is one of the most painful occasional accompaniments of advanced life. It is almost equally painful to the patient, his friends, and the doctor—the one a most acute sufferer, the others with their deepest sympathies aroused, the last compelled to be a spectator of ravages he can neither avert nor combat, but only alleviate. Fortunately for all, it is not a very common disorder.

By far its most frequent cause is calcification or other similar changes in the arteries, whereby their calibre is diminished and their walls roughened,—conditions of themselves most favorable to the formation of thrombi, which extend often over a very wide territory; and when to these are added the natural enfeeblement of the heart from old age, the wonder rather is not that it ever should occur, but that so many of the aged escape.

Two peculiar forms exist, distinguished sharply by their etiology from the typical variety; the one a complication of diabetes mellitus, and the other a result of ergotism. The pathology of the former is obscure. It certainly does not arise from any such arterial changes as those already alluded to, and though the pulse is enfeebled, yet the heart is but slightly altered, if at all, and apoplexy, so frequently seen in Bright's disease with its arterial lesions, is rare in diabetes. Most probably the blood itself is at fault. Either it is impoverished to an extent incompatible with proper nutrition, especially on the outskirts of the vascular system, or from loss of water and other changes its coagulability is increased to such a degree as to favor spontaneous thrombi. Both of these causes would be still more potent if the heart be weakened even in a small degree, and very probably all these causes combine in not a few cases. Certain it is that the chilliness of the surface, the dryness of the skin, the frequent boils and carbuncles, and the diminished cutaneous sensibility, all point to such natural and plausible explanations.

The other form—that which follows ergotism—is due, undoubtedly, to vascular spasm by contraction of the muscular coat of the arteries, for it is upon the involuntary muscular fibres whether in the uterus, the intestine, or the arteries, that ergot expends its force. This form of gangrene has swept off its victims by thousands where it has arisen from eating the diseased rye as bread. Then both from the quantity eaten and the continuous use of the fungus, the amount of ergot ingested must be very large indeed—vastly in excess of any probable, and almost of any possible, amount given medicinally. Fortunately in this country, both from the general well-being of the people and the very general use of wheat for bread, this is, we believe, an unknown disease.

But the question often arises in the minds of physicians as to the possibility of ergotism and its resulting gangrene, following the medicinal use of the drug. This is more a theoretical possibility than a practical fact. It is doubtful, indeed, whether there have been any cases of gangrene following the medicinal use of ergot. We have used Squibb's solution hypodermatically (a filtered solution in water of the inspissated fluid extract and six times the strength of the crude drug) in forty-minim doses on alternate days, for from three to five months; Dr. D. H. Kitchen recommends its use in epilepsy for months; and Dr. H. C. Wood, in congestion of the spinal cord, gives an ounce of the fluid extract three times a day, all without evil results. The prodromic symptoms are sufficiently clear to warn us if by any possibility evil should be threatened. Marked chilliness, formication, and pain in one or both feet or the fingers, pain in the back, muscular cramps, nausea, giddiness, weak pulse, dilated pupils, and disturbance of the uterine functions announce the danger, and the remedy should be instantly discontinued and heat and stimulants be used. Indeed, fortunately, the diseases for which its continued use is demanded are such, that an occasional intermission of a week or a month in its use, is not only feasible, but wise. The fact that the gangrene begins in the deeper tissues and works out to the skin may mask the trouble, but other symptoms will probably exist to put us on our guard.

It must not be forgotten that ergot has been one of our most valuable remedies in diabetes. Gangrene, if it follow either the disease or the remedy,

is of course even more possibly a sequel if the two conditions coexist. Usually diabetic gangrene differs in its course from the ergotic form, and begins with a small ulcer, from which it spreads phagedenically, or it may follow a blister or a boil. But the cases of gangrene, in which these two possible causes have been combined, are so few that the character of the local manifestations and the possibility of differentiating the two causes have been as yet insufficiently studied. We should, therefore, welcome the report of every such case as a valuable contribution to our knowledge. Indeed, it is only a score of years since attention was drawn to the coexistence of gangrene and diabetes, and it is, therefore, no wonder that it has not yet received all the attention it deserves.

The question of operative interference in senile gangrene is as yet unsettled. The condition of the arteries, or of the blood, makes the prognosis unfavorable, for the causes of the gangrene are not local but general. Hence, if amputation be done the disease is apt to return in the stump. But in those cases in which a distinct, well-defined, and stationary line of demarcation forms the prospect is more hopeful. Several cases have been reported of late years, in which the result has been a happy one, and in this our personal experience coincides. But sufficient time should be given to ensure the fact that the natural limitations of the gangrene have been reached.

THE SOCIETY FOR THE PROMOTION OF HUMAN SUFFERING.

SUCH it is, and such it ought to be called. The humane but misguided women and men who have lately organized the American Anti-Vivisection Society in this city are the victims of a sentiment, laudable in itself and when restricted to its proper limits, but which has so far led them astray that, unconsciously and unintentionally, if they succeed, they will actually promote human suffering, and shorten many human lives. And not only will humanity suffer, but the very brute creation of which they are the supposed champions. The splendid and beneficent researches of Pasteur, by which the lives of thousands of animals are saved every year, could not have been made but for vivisection; and the possibilities of incalculable good to the human race in the future prevention or cure of scarlet fever, diphtheria, measles, and other such zymotic diseases, and even of consumption, that are suggested by the researches of Pasteur, Koch, and others would have no existence. The hopes which these investigations have aroused, it is true, may prove delusive, but, on the contrary, they may be realized. We seem to be at least on the right road, thanks to vivisection.

These earnest but mistaken people are not of the kind to hide their light under a bushel. They "mean business." They are active, energetic, liberal; and, undaunted by former defeats, they mean to succeed—if they can. They are using every means at their command. Public meetings furnish a ready method for disseminating ideas to many people at once, not only to the audience of the evening, but also to the entire community through the newspapers. Pamphlets are being distributed broadcast asking for money and influence, and telling most dreadful tales of the cruelties of the vivisectionists; and even during the late session of the Pennsylvania State Medical Society, a communication from the Anti-Vivisection Society was presented. Its tone was respectful, and very properly it was referred to a committee to report upon it at the next meeting. We trust that the report will be an able, calm, and careful presentation of the facts, and will show unmistakably the advantages of the scientific and exact methods of research by experiments on animals as applied to surgery, physiology, pathology, therapeutics, etc. As undoubtedly the Society will extend its operations to other State societies, let this report be a solid foundation upon which they may build.

We regret especially to see among the pamphlets so freely distributed by the Society, one by Mr. Lawson Tait. Unlike the Society here, which masks its ultimate purpose of abolition under the present movement for regulation only, Mr. Tait boldly says it ought to be put an end to "without any kind of reserve whatever." The paper is well written, as is all that Mr. Tait publishes, but not only does he assume that he alone is right in matters really still unsettled, but he astonishes us by some of his statements. He claims that evolution, if it be admitted, clothes the lower animals with *equal* rights with man; that vivisection "can be discussed by an educated layman, as well, perhaps better than by medical men;" that Harvey is claimed as the discoverer of the circulation only by reason of "insular pride;" that such "wholesome scepticism concerning drugs has been introduced by the medical schism of homœopathy; that he looks upon all new drugs with great suspicion;" whereupon he declares that chloral and carbolic acid have done more harm than good, and physostigma is of no practical service; that vivisection has done nothing of value in the surgery of the arteries; that Syme and Ollier, in their subperiosteal surgery, "were only attempting to establish what had long been proved;" he throws grave doubts on the value of vaccination, denies the value of Pasteur's researches, and approves of Taylor's condemnation of all experiments as to poisons, and "particularly those which are directed towards the discovery of an antidote to snake-bite." He had

better read Weir Mitchell and Reichert's recent researches. His ideas on these subjects are enough to prove to "Dr. Bowditch of New York," whom he cites, or to any other intelligent *medical* man, the want of confidence that must attach to all his other statements. His new-born zeal has warped his judgment. He has always been apt to jump at conclusions, and his general unreliability is in this instance conspicuous.

One of the strongest arguments (as distinguished from sentiment) that influences the general public, is the moral one—that the Creator cannot so have organized His government as to allow one of his creatures to derive benefit from the torture (as they are pleased to call it) of another. Yet they would unhesitatingly ride a horse to death to get a surgeon in case of serious hemorrhage; or in shipwreck, "torture" animals by tossing them overboard to drown unpitied, if by so doing they could save their own lives. And what is a just war, but the most terrible example of such vicarious suffering in man himself? It is passing strange that those who use such an argument forget that, excluding vivisection, the only other means of progress in medicine is by the lessons we learn from the prolonged torture of human beings by disease; the only method available by which to study the action of drugs by experiments on these poor sick folk. Surely if we can substitute a few of the lower animals for many men in such a case, we ought to do so; and if Mr. Lawson Tait and a few more on the one side say we cannot do so, and ten thousand better men on the other say we can, any judicial mind in balancing testimony must yield to the greater weight of authority.

And what saith the Scripture, if its authority be desired? "Thou madest him to have dominion over the works of thy hand; thou hast put all things under his feet; all sheep and oxen; yea, and the beasts of the field, the fowl of the air, and the fish of the sea, and whatsoever passeth through the paths of the seas."

TANNATE OF CANNABINE.

THIS product of Indian hemp has been lately used by FRONMULLER, with distinct advantage as a hypnotic. Although most of our readers are doubtless familiar with this fact, it may be useful to lay before them some recent contributions to our knowledge of the subject.

The tannate of cannabine is a yellowish-brown powder, insoluble in water and in ether, but soluble in alcohol; it has but little taste, somewhat like tannin, and no odor. Fronmüller reports having used it 57 times in hospital and 6 times in private parctice, in 21 men and 42 women. Of these subjects, 40 suffered from pulmonary tuberculosis, 4 from abdominal tumor, 3 from chronic bronchitis, 2 from lead colic, 1 from acute pneumonia, 1 from psychical troubles, 3 from alcoholism, 4 from mercurialismus, 2 from asthma, 1 from perimetritis, and 1 from abdominal neuralgia. All of these had taken more or less morphia subcutaneously. Without entering into details, it will suffice to give the results, which are the more satisfactory since the remedy was used in so many morbid states.

Fronmüller concludes that the tannate of cannabine is a hypnotic of the first importance, and is free from disagreeable effects, not causing intoxication or inducing constipation. The doses given ranged from one to fifteen grains.

THE NEW YORK CITY HEALTH BOARD.

MAYOR EDSON, of New York City, has nominated Professor Charles F. Chandler, of Columbia College, as Health Commissioner and President of the City Board of Health, and this nomination has been rejected by the Board of Aldermen by a vote of thirteen to ten, those voting for its rejection being eleven Tammany Hall Democrats and two Republicans.

The cause of the rejection was solely due to the desire of the Tammany managers to secure the office for one of their own men, and not to any special hostility to Prof. Chandler. As the appointment is for six years, at a salary of $5,000 per year, and as the holder can control a number of subordinate appointments, it will be seen that, from a politician's point of view, it is worth fighting for.

The rejection of Prof. Chandler, who has held this office for ten years, and done much good work in it, has given rise to great dissatisfaction among the leading business men and property owners of the city, and a petition, signed by about three thousand such gentlemen, requesting Prof. Chandler's confirmation, has been presented to the aldermen through the Mayor, but with no effect. Thus far, the Mayor has not sent in any other name, and until he does so, we believe that Prof. Chandler continues to hold the office.

When the magnitude of the interests involved in this appointment is considered, in connection with the fact that unusually great discretionary powers have been conferred upon the New York City Board of Health because of the confidence felt by leading citizens in the knowledge and honesty of its members, and more especially of its President, and when, on the other hand, the contemptuous indifference displayed by the aldermen to the recommendations and wishes of the best men in the city is noted, it is enough to discourage the most enthusiastic advocate of municipal sanitation.

It is to be hoped, however, that the Mayor will remain firm, and prevent the effort which is being made to subordinate the health interests of a great city to the pecuniary needs of half a dozen politicians.

PROVING ONE'S OWN TESTAMENTARY CAPACITY.

THE new law of Michigan seems based on marvellously good common-sense, and will avoid a deal of annoying *post-mortem* litigation over wills by establishing, *ante mortem*, the testamentary capacity of the testator.

It provides that the testator may go into court, giving notice to all concerned, and have his own will probated. Any doubt as to his sanity must be settled then and there. Nor will the opinion of any supposed heir be warped by a question as to his personal interest, for the contents of the will need not be divulged. The only question is whether the testator is mentally fit to make a will. What flaws our legal friends may find in the method, we do not know, but it certainly commends itself to the common mind as a most excellent way of avoiding trouble and unseemly conflicts in expert testimony.

THE Governor of New York, notwithstanding the protests of the New York County Medical Society and of the advisory council of physicians who support the New Code, has signed the bill which decides the legality of the incorporation of the United States Medical College. The State Supreme Court recently rendered a decision adverse to the charter; but this bill, which has now become a law, settles the question also of the legality of all the diplomas which have hitherto been granted by the College, and its M.D.'s become "legally qualified practitioners" within the meaning of the New York Code, and as such are entitled to be met in consultation by its supporters. It will be interesting to watch the effect of this professional recognition upon the business of duly chartered diploma mills.

THE Fifth Annual Congress of the American Laryngological Association which has just closed, and a full report of the proceedings of which will be found in another column, marks an era in the history of laryngology in this country. The papers read covered a wide range of subjects. They were of unusual interest, and elicited general and very instructive discussions. The meeting was well attended by members from all sections of the country, and much of the credit of its success is due to the admirable manner in which all the details of the meeting were elaborated by the executive management. It is therefore not surprising that it was determined to meet next year again in New York.

SOCIETY PROCEEDINGS.

MICHIGAN STATE MEDICAL SOCIETY.

Eighteenth Annual Meeting, held at Kalamazoo, May 9 and 10, 1883.

(Specially reported for THE MEDICAL NEWS.)

THE Eighteenth Annual Session of the Michigan State Medical Society convened in Kalamazoo, at 10 A.M., May 9, 1883. The attendance was larger than at any previous session.

MAY 9TH.—FIRST DAY.

The *President*, DR. GEO. W. TOPPING, of De Witt, called the meeting to order.

HON. E. W. DE YOE, President of the Village, then extended a cordial welcome to the members of the Society.

THE EXECUTIVE COMMITTEE

reported through DR. FOSTER PRATT, *Chairman*, that invitations had been received from Superintendent Palmer, of the Michigan Asylum, for the Society to visit the institution on Thursday; and from the village authorities to visit the municipal establishments of the place.

The *Secretary*, DR. RANNEY, then read his report.

DR. SMART, the *Treasurer*, then rendered his report, showing an unexpended balance of $438.26.

DR. WM. BRODIE, of Detroit, read a paper on

ANEURISMAL TUMORS OF THE SCALP,

describing a case occurring in a woman, æt. 47, who fell upon the walk striking the back part of her head, and in a few hours felt a small lump on the left side of the upper portion of the occipital bone, which gave her some uneasiness, and which she ascribed to the fall. The swelling increased to the size of a goose egg, and was painful. Other small tumors appeared on the left side of the head, the largest on the upper and posterior portion of the parietal bone. On exploring with a trocar the largest tumor, it was found to contain arterial blood. A distinct bruit could be heard, synchronous with that of the heart, and the small tumors developed the same sounds.

A bistoury was passed into the tumor, when the blood poured out *per saltum*, as though an artery had been opened. This confirmed the diagnosis for this tumor as well as the rest. The wound was then closed. On the second day a violent attack of erysipelas took place, so severe that for a few days her life was despaired of, as the inflammation extended over the whole scalp and face. She, however, recovered from the erysipelas, but without any beneficial change in the character of the tumors, as hoped for from the inflammation and suppuration.

Dr. Kaiser was with him in the case, and they discussed the propriety of either ligating the occipital, the temporal, or the external carotid arteries, but in view of the free anastomosis of these arteries and their branches, also the character of the arterial structure as evinced by the peculiarity of the heart's action, and of the anastomosing arteries of the scalp, as manifested in the formation of smaller tumors, not directly caused by the primary injury, besides the immediate danger of both carotids being ligated at the same time, ligation was deemed inadvisable. Pressure was considered, but was dismissed as impracticable in the case of the large tumor. Electrolysis was suggested, but the patient declined, for the present, any further interference. No pulsation could be felt in any of the tumors. The authorities which they had been able to consult

gave them but little information as to the proper treatment of the case.

The SECRETARY announced the names of sixty-six new

APPLICANTS FOR MEMBERSHIP.

The PRESIDENT referred the applications to the Committee on Admission, and requested the applicants to personally appear before the Committee.

AFTERNOON SESSION.

President TOPPING called Vice-President S. S. French to the chair, and then delivered

THE ANNUAL ADDRESS.

He spoke of the supernaturalistic ideas prevailing, now in one form, and again in another, which have clung to the science of medicine. Men who in every other respect are men of learning and good judgment, here, of all other places, seem to lose their commonsense. The more of mystery about a man, or a drug, or a mode of treatment, the more does it develop this latent superstition, and hence it is that so many find it to their interest to violate our Code of Ethics, and to indulge in the myriad deceptions of quackery.

He then referred to the important work which had been accomplished by the State Board of Health in giving to the public their circulars and other documents in reference to the causes of disease, and how to prevent them. There could be little doubt that the ravages of scarlet fever, smallpox, and diphtheria had, by these means, been greatly diminished.

DR. TOPPING then called attention to the overstocking of the profession. He said: "Of the 585 people which an equal distribution would allot to each physician, only a very small percentage, are very likely to become paying patients to him, even if they should be so unfortunate as to need to employ him; therefore, many physicians will necessarily have to seek other employment for support; after having spent their time and means in acquiring a profession by which they had hoped to make a living. The cheapening of a professional education through State support allures many young men into the profession of medicine, who would otherwise have entered into some other avocation more beneficial both to themselves and the public. It must be evident to all, that this country is already overstocked with physicians, therefore it cannot be necessary to tax the people to produce a more redundant supply. Our State medical schools are among the most active agents in producing this oversupply of physicians. Yea, more, by means of the hospitals under their charge and State support, they are enabled to offer cheaper medical and surgical treatment than can be proffered by the general practitioner, who cannot resort to taxation to make good his exhausted finances. The State Medical School is a materfamilias who gives the world a numerous progeny, and then does her best to cut off and destroy their means of support. The University Hospital is filled with patients who go there through economic considerations, many of them being abundantly able to fee a physician at home, and would do so were not cheaper terms offered them at Ann Arbor. These hospitals are extensively advertised at public expense, and individuals from far and near are induced to abandon their home physicians for the more advantageous terms, which hospitals under State support are enabled to offer them."

The President then referred to the relations existing between the profession and the medical department of the University of Michigan. That there are evils existing in the medical department of the University, which need correction, he believed to be evident to all fair-minded impartial men. To the end that something may be done to correct these evils, and to bring the medical school of the University in proper and profitable harmony with the medical profession, he ventured to offer certain suggestions for consideration.

The address elicited an animated discussion, and objections were made to having that portion of it relating to the University referred to the publication committee. On motion of DR. PRATT, this portion was referred to a special committee, consisting of Drs. Andrews, J. H. Jerome, and F. M. Oakley.

DR. J. C. LUNDY, of Detroit, read some

CLINICAL NOTES ON ERRORS OF REFRACTION.

He said it was a fact well known to many practitioners that errors of refraction may, and often do, produce a variety of eye troubles as well as other disturbances more or less serious in their nature. He had seen patients to whom powders, pills, and potions had been administered *ad nauseam* for headaches, vertigo, so-called bilious attacks, etc., without one iota of relief, and who were quickly cured of their maladies by the proper adjustment of spectacles. Such patients, of course, had some error of refraction, but the disturbing influence of this condition was not understood by the physician.

While headaches of a general or frontal character occur commonly enough as the result of eye-strain, there was a particular form of headache to which he desired to call attention in this connection. In a word, it resembled very closely the headaches due to congestion or inflammation of the fundus uteri. He was satisfied that pain of a dull, throbbing character, with a sense of weight and fulness, and confined to the vertex, with or without pain at the nape of the neck, was due, in many instances, to straining of the eyes. To illustrate this point, notes of several cases were given. In some of these cases, the patients had been previously treated for imaginary uterine disease; others were treated for so-called bilous attacks, etc., but without benefit. In every case, complete relief was afforded by spectacles, which corrected existing errors of refraction.

Numerous cases were reported, showing the influence which eye-strain exerts in producing disease of that organ, and the difficulty of curing such cases unless the error of refraction was first corrected.

DR. CONNOR mentioned two cases which had come under his observation. In one, a physician, astigmatism had so excited the brain as to produce insanity, which disappeared after wearing glasses. In the other, after correcting errors of refraction, epileptic attacks had grown less severe.

On motion, the

COMMITTEE ON ADMISSIONS

was ordered to report the next morning at the beginning of the session.

MAY 10TH.—SECOND DAY.

MORNING SESSION.

The Society was called to order at 9.30 A.M. by the President, and the roll called by the Secretary.

THE COMMITTEE ON ADMISSIONS

then rendered their report, recommending quite a large number of applicants, and stated that, for want of time, a large number of applications had not been sufficiently considered, and asked for more time. The application of Dr. George A. Hendricks, of Ann Arbor, was reported on adversely, and his case was referred to the Judicial Council.

DR. TYLER, *Chairman* of the

COMMITTEE ON NOMINATIONS,

reported the nominations for all officers below president, the president being chosen by ballot.

PROF. VAUGHAN, of the University, offered as a substitute a full set of nominations. The Committee's nominations, after discussion, were adopted by a large majority.

BALLOTING FOR PRESIDENT

ensued. DR. A. F. WHELAN was nominated by Dr. Smart, and supported by Drs. Hitchcock and French.

PROF. MACLEAN then rose, and said that though his friends had proposed to nominate him for president, he would move to have the ballot of the Society cast unanimously for Dr. Whelan.

On motion of DR. TUPPER, moved that the Secretary be instructed to cast the vote of the Society for Dr. A. F. Whelan, which was done, and Dr. Whelan declared unanimously elected President.

The following were recommended and elected

OFFICERS FOR THE ENSUING YEAR:

President.—A. F. WHELAN, M.D., of Hillsdale.

Vice-Presidents.—DRS. HORACE TUPPER, of Bay City; J. S. HAMILTON, of Tecumseh; H. B. BARNES, of Ionia; AUGUSTUS KAISER, of Detroit.

Secretary.—DR. GEORGE E. RANNEY, of Lansing.

Treasurer.—DR. A. R. SMART, of Hudson.

Judicial Council (to serve for three years).—DRS. FOSTER PRATT, H. B. SHANK, and S. P. DUFFIELD.

Delegates to the American Medical Association.—Drs. H. C. Wyman, J. B. Book, Wm. Brodie, L. Connor, H. O. Walker, and E. L. Shurley, of Detroit; E. S. Dunster, A. B. Palmer, and W. F. Breakey, Ann Arbor; Foster Pratt, Kalamazoo; A. R. Smart, Hudson; J. H. Bennett, Coldwater; J. Andrews, Paw Paw; S. S. French, Battle Creek; C. H. Lewis, Jackson; F. K. Owen, Ypsilanti; Jas. Munson, Pontiac; Hugh McColl, Lapeer; A. F. Hagadorn, Bay City; J. H. Jerome and L. W. Bliss, Saginaw; W. N. Smart, Grand Haven; Geo. E. Ranney, Lansing; I. R. Shephard and C. V. Beebe, Manistee; W. E. Dockery, Pentwater; W. L. Dickinson, East Saginaw.

DR. POST, of Lansing, presented a paper on

WATER AND ITS RELATION TO HEALTH AND DISEASE.

The paper was practical, and gave most of the tests used in water analyses, the method of preparing the reagents, and the deductions drawn from the presence of many impurities. He related his experience in examining ice which gave a bad taste to the water in which it was placed, and an interesting account of two cases of bad-tasting water—one of which was traced to a fresh-water sponge which gave the water a cucumber taste and smell; the second case was traced to a fungus which was found to grow upon fish, killing the fish, but no trace of the fungus could be found in the water.

Of chlorine, he said that no single indication is of so great importance, and that the purity or impurity depends quite largely on its presence or absence. How salt, which is considered harmless of itself, can become a signal of danger in water, is easily understood. No mineral substance is so widely diffused as common salt; it exists in the air and in the earth, it is washed out of the soil, and is found in all well and spring water, though often in minute quantities, and is carried by our rivers down to the sea. It is difficult to determine what is the normal amount of salt in pure water, but it cannot be large. Should it reach four or five grains per gallon, it should certainly be looked upon with suspicion. Sewage always contains salt, either from the house-drain or water-closet; and if water is found to contain chlorine, it is undoubtedly contaminated from one of these sources.

DR. H. J. REYNOLDS, of Orion, read a paper on the

ETIOLOGY OF URETHRAL INFLAMMATION.

He thought that we should be very careful of our diagnosis of urethral troubles, as they often involved the happiness and welfare of others besides the patients. He classed the inflammation as simple and specific, and gave something of the recent history of these cases. He thought that very often the inflammation was caused by some irritation applied to the parts. He seemed to think that we resorted too often to severe remedies, and that milder remedies, with time and patience, brought about better results in most cases.

AFTERNOON SESSION.

DR. T. N. REYNOLDS, of Detroit, read a paper on

TIMELY CATHARSIS.

He recommended the use of cathartics in the early stages of labor and pneumonia. He had aborted an attack of rheumatism by free catharsis; the same result had been reached in one case of trifacial neuralgia, and in the delirium following cranial injuries. He recommended three drops of croton oil, in water. He used the same for puerperal mania, violent hysteria, and uræmia. He did not discuss the abuse of cathartics. For mild action, he recommended a glass of warm water, or a cup of coffee, in the morning.

In the discussion following, attention was called to the fact that free catharsis did not necessarily imply that the bowels had been emptied. DR. SMART mentioned one case where about a peck of fecal matter had been removed after apparently free catharsis.

DR. H. O. WALKER, of Detroit, presented a paper upon the use of

PLASTER OF PARIS AS A SURGICAL DRESSING.

He briefly referred to its first introduction and history up to the present time, followed by a description of the mode of preparing and applying, together with numerous illustrations of a variety of cases to which it is applicable, both in the treatment of fractures, diseased joints, and deformities.

DR. A. R. SMART, of Hudson, read a paper giving a

HISTORY OF A DISEASED EAR,

which had afflicted the patient about thirty years. The patient suffered much pain in the diseased ear and an almost constant offensive discharge. On examination with a probe, he thought he discovered necrosed bone. Grasping the substance with his forceps, he withdrew what proved to be a glove-button. This button had caused much suffering, and nearly destroyed the hearing in that ear. The pain and discharge almost immediately ceased on removal of the foreign body.

REPORT OF COMMITTEE ON THE PRESIDENT'S ADDRESS.

The special committee to whom was referred that portion of the President's address, which caused so much controversy, reported that the address contains the following points or propositions, briefly stated, which he suggests for the consideration of the Society:

1. The best means of securing a higher standard and attainment in the profession.

Your committee can see no reason why the Society, if time permitted, might not profitably consider and discuss the above proposition.

2. The possibility and desirableness of combined action between the Board of Regents and the State Medical Society in securing such legislation as is now generally needed to protect the people against the increasing number of irresponsible and unqualified medical practitioners.

With regard to the above, your committee believe that the only portion liable to suffer from its discussion would be that class of practitioners to which it alludes.

3. The manifest injustice of giving gratuitous treatment at the University Hospital to patients able to pay for medical services, and for whom such treatment was not originally intended.

As a large portion of the profession of the State have complained of such gratuitous treatment, and on apparently good and reasonable grounds, your committee can see no reason why the Society might not profitably consider and discuss this proposition.

4. As to the propriety and justice of some of the professors in the University, treating patients in hospital wards attended by hospital nurses, and exacting pay for such treatment for their own personal emolument.

While at first thought it might seem that this Society had no interest in this matter, other than in common with other taxpayers of the State, still your committee believe that the manifest injustice of this practice (if it exists) to the profession at large might be properly discussed by the Society.

5. As to the propriety of the practice of extolling the qualifications of the medical and surgical staff of the hospital or belittling those of the profession at large, to the great injury of the latter, in advertisements scattered broadcast throughout the State.

Your committee believe that there may be some just ground of complaint on the part of the profession at large, and see no reason why this statement (if true) may not be properly discussed by those most interested.

As the foregoing questions were simply suggested by the President as proper subjects for consideration by the Society, your committee see no impropriety on the part of the President in suggesting, or in that of the Society in calmly and dispassionately considering and discussing such questions.

The report called forth quite an animated discussion.

Prof. Palmer, of the University, spoke at length. He made a specific denial of each charge against the Medical Department and Hospital, and was heartily endorsed by Prof. Maclean, who covered the same grounds, and added that he thought if members would visit the hospital, laboratory, etc., they would go away with different impressions.

Dr. Hitchcock also spoke for the University.

Dr. Brodie said that the impression had gone about through the State (and even existed in Washtenaw County), in which Ann Arbor is situated, that the public property of the State at Ann Arbor was being used for private purposes.

On motion of Dr. Pratt, the report of the Committee and the remarks of Drs. Palmer, Maclean, Hitchcock, and Brodie, together with the President's address, were referred to the Publication Committee.

Dr. Henry B. Baker read a short paper on the subject of the most common

CAUSATION OF DIPHTHERIA,

asking attention to the mode of studying the subject by means of statistics of deaths during long series of years in many cities, States, and countries. He presented a table of such statistics showing the number of deaths in each year, the table having the years of maximum mortality marked to show what he called the "crests of epidemic waves," which seem to recur with considerable regularity. "About twenty instances in cities and thickly-settled countries, where means of contact are greatest, show an average period of between five and six years. In sparsely-settled country districts, four instances show an average period of about fourteen years"—between the crests of the waves. He stated the age of greatest liability to death from diphtheria to be the ages under ten years, particularly the ages of three, four, and five years. He thought the statistical evidence strongly favors the view that the most common and the most general cause of diphtheria is contact with something derived from a previous case of diphtheria; and that, "besides the comparative insusceptibility of communities in which many children have died with or recently had diphtheria, the comparative extent and complexity of the modes of intercourse in city and in country districts is an important factor in determining the length of the period between epidemic waves of diphtheria."

Dr. E. B. Ward, of Laingsburg, read a facetious poem, which created much merriment.

NEXT PLACE OF MEETING.

The invitation extended to the Society by the physicians of Grand Rapids to hold its next annual session at that place was accepted, and the Society then adjourned.

MISSOURI STATE MEDICAL ASSOCIATION.

Twenty-sixth Annual Session, held at Jefferson City, May 15, 16, and 17, 1883.

(Specially reported for The Medical News.)

First Day. May 16.

The Annual Meeting of the Missouri State Medical Association took place at Jefferson City, May 15, 16, and 17, 1883. The President, Dr. A. E. Gore, of Paris, in the chair. An

ADDRESS OF WELCOME

was given by Governor Crittenden, who took occasion, in the course of his remarks, to criticise severely, the National Code of Ethics, and to prophesy the speedy downfall of the code and the destruction of walls of separation between the schools of medicine. In closing, he paid a merited tribute to the memory of Dr. John T. Hodgen.

The President responded in behalf of the Association, and entered a vigorous protest against the position suggested by the Governor; and declared emphatically his own position on the side of supporting the Code of Ethics.

The enthusiastic applause which followed, proved that he had well voiced the sentiment of the Association in thus defending the Code of Ethics.

Dr. Halley, of Kansas City, introduced a series of resolutions urging upon Congress the appropriation of $250,000 to erect a suitable fire-proof building for the preservation of the

ARMY MEDICAL MUSEUM AND THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE.

Also urging the appropriation of $10,000 per annum for the maintenance of the library, and of such sums as may be necessary to secure the completion of the *Index Catalogue*.

Dr. G. M. Dewey, of Keytesville, read a paper entitled

A FEW REMARKS WITH REFERENCE TO THE CODE.

Some of the points made were well taken, and were heartily approved by the Association. He deprecated the establishment of a State Board of Health in which the different schools of medicine should be represented.

In the discussion following this paper, Dr. Halley, of Kansas City, called attention to the admirable working of a Board of Health and Board of Examiners in the Dominion of Canada.

Dr. King, of Sedalia, gave some account of the history of the legislation in this State which has resulted in the passage of laws establishing a Board of Health and to regulate the practice of medicine and surgery. He remarked that the legislation thus far secured is only a commencement, and that future legislation will be influenced very largely by the recommendations of the Board of Health now provided for.

DR. ALLEN, who had taken an active part in the matter of securing the legislation referred to, gave some fuller account of it, and called attention to the fact that the aim and object of all this legislation was to secure the safety and promote the interests of the citizen, not to advance the interests of the medical profession.

DR. C. A. TODD, of St. Louis, introduced a resolution repudiating the use of the term

ALLOPATH

with reference to the members of the regular profession. This was unanimously adopted.

EVENING SESSION.

Greetings were ordered to be sent to the Associations of Kansas and Illinois.

DR. FORD, of St. Louis, presented a long and exhaustive

REPORT ON PROGRESS IN GENITO-URINARY SURGERY.

He discussed some of the difficulties of genito-urinary, noting the dangers from hemorrhage, influence of urine passing over the wound, deep site of operation. He discussed at length the influence of stricture of small and large calibre, and the modern operation of lithotrity or litholapaxy. The reading of the first half of the paper having occupied more than an hour, the remainder of the paper was referred, without reading, to the Committee on Publication.

DR. TRADER, of Sedalia, read a brief paper upon the use of the

ELASTIC LIGATURE IN SURGERY,

showing its advantages and the limitations of its usefulness.

DR. ALLEN presented an oral report from the

COMMITTEE ON MEDICAL LEGISLATION,

giving account of the work done and the results accomplished in the direction of medical legislation.

A resolution was then adopted tendering the thanks of the Association especially to the members of the medical profession and others, who were most active in securing this legislation and to the General Assembly for the enactment of those laws at the late session of that body.

SECOND DAY, MAY 16.—MORNING SESSION.

The first order of the day was the report of the commitee on the

PROGRESS OF MEDICINE,

presented by DR. LESTER, of Kansas City, in which he treated particularly of the bacillus tuberculosis, treatment of typhoid fever, and treatment of rheumatism by the salicyl compounds.

DR. KING, of Sedalia, spoke emphatically in favor of the cooling bath in typhoid fever.

DR. TODD, of Kansas City, did not believe that the direct abstraction of heat is of advantage in itself, and thinks that the view of those who advocate the cold baths is pathologically erroneous.

DR. DEWEY, of Keytesville, spoke in condemnation of the use of large doses of quinine in typhoid fever.

DR. ALLEN said that he had of late used tincture of digitalis with decided advantage in the later stages of typhoid fever when there is a tendency to failure of the heart.

COMMUNICATIONS FROM THE TRI-STATE MEDICAL SOCIETY

were then presented, inviting the appointment of delegates to the meeting of that Society, to be held at Indianapolis; also from the

KANSAS STATE MEDICAL SOCIETY,

inviting appointment of delegates from each society to the other.

DR. J. W. BRENT, of Tipton, read a paper on

FORCE,

which, not being specially medical in its scope, elicited no discussion.

DR. S. POLLAK, of St. Louis, read a paper on

JEQUIRITY IN OPHTHALMIA,

reciting his personal experience in the use of this new remedy, and fully endorsing the favorable reports that have been published with reference to that drug.

DR. HALLEY, of Kansas City, read an abstract of a more extended paper, discussing the *Nature and Classification of Tumors.*

The paper of DR. E. J. WARTH, of Nevada, on *Spontaneous Evolution*, was read by title.

DR. B. F. WILSON, of Salisbury, read a paper on *Bacteria, their Nature and Influence*, which Drs. Allen, Hart, Hughes, Porter, Potter, Campbell, and Johnson discussed at some length.

AFTERNOON SESSION.

THE ADDRESS OF THE PRESIDENT

was the first order of business.

THE PRESIDENT, DR. GORE, showed some of the changes that have taken place in the course of medical practice during the years since his student-days, and pointed out how limited is the progress that has been made, and how great is the need of additional progress. He also referred to the defects of medical education with regard to practical points.

DR. T. J. NORRIS, of Macon, presented a report of

THE COMMITTEE ON MEDICAL EDUCATION,

containing extracts from letters received from a number of prominent physicians in this State and elsewhere in response to letters of inquiry regarding their views on medical education.

A motion was passed to

AMEND THE BY-LAWS

by limiting the reports of standing committees to thirty minutes in length, and other papers to twenty-five minutes in length.

EVENING SESSION.

A biographical notice was read by DR. E. M. NELSON, of St. Louis, in memoriam of

DR. JNO. T. HODGEN,

whose death occurred so shortly before the last meeting of this Association that no opportunity was afforded for the preparation of a sketch.

DR. P. V. SCHENCK, of St. Louis, then read a very able and thoroughly prepared paper, in which he discussed the

VITAL AND HEALTH STATISTICS OF THE SEXES,

showing that female lives are in truth better risks for life insurance than are male risks, contrary to the view generally held by insurance actuaries heretofore.

A lady representative of the Sons of Temperance was granted permission to address the Association for five minutes on the subject of temperance, which she did.

DR. ALLEN, on behalf of a special committee, made a motion that the

TIME OF THE ANNUAL MEETING

be changed from the third to the second Tuesday in May, to allow the attendance of delegates from this

Association upon the meetings of the Kansas and Illinois Associations, both of which met on the third Tuesday of May. A motion was also passed, providing for the appointment of delegates to these Associations.

DR. N. W. HARRIS read a paper on

GLAUCOMA,

giving experience of the disease in his own case.

DR. F. B. TIFFANY, of Kansas City, read a paper on the same subject, discussing the pathology and treatment of the disease.

THIRD DAY, MAY, 17.—MORNING SESSION.

The first paper of the morning was the special

REPORT ON ALCOHOL,

by DR. J. M. ALLEN, of Liberty. In accordance with the suggestion of the paper a committee of three was appointed to report at the next meeting on the relations between spirit-drinking, insanity, and crime.

The following papers were read by title and referred to the Committee on Publication, the authors not being present to read them in full:

Injuries to the Head, by DR. R. F. BROOKS, of Carthage.

Case of Congenital Encephaloma, by DR. J. H. DUNCAN, of Columbia.

ELECTION OF OFFICERS

being the special order of the day, DR. E. H. GREGORY, of St. Louis, was nominated as *President*, and the PRESIDENT was requested to cast the vote of the Association for Dr. Gregory. The other officers as nominated by the Committee on Nominations, and so elected by the Society, were as follows:

Vice-Presidents.—DRS. O. A. WILLIAMS, of Morgan Co.; J. D. GRIFFITH, of Jackson Co.; JNO. H. DUNCAN, of Boone Co.; T. J. NORRIS, Macon Co.; C. H. HUGHES, of St. Louis.

Recording Secretaries.—DRS. A. H. OHMANN-DUSMENIL, of St. Louis; and D. V. WALL, of Jasper Co.

Corresponding Secretary.—DR. N. F. ESSIG, of Clinton Co.

Treasurer.—DR. C. A. THOMPSON, of Cole Co.

Sedalia was chosen as the *next place of meeting* of the Association.

A resolution was passed approving the record of

THE NATIONAL BOARD OF HEALTH,

and urging upon Congress the appropriation of sufficient funds for the efficient work of this Board.

DR. T. F. PREWITT, of St. Louis, gave a verbal report of a *Case of Rhinoplasty*, presenting photographs of the patient.

DR. N. M. BASKET, of Moberly, read a paper entitled *Some Suggestions on Sanitation.*

DR. W. A. HARDAWAY read a paper entitled *Electricity in Dermatology*, giving the result of ten years' experience in the use of this agent.

DR. T. E. POTTER read a paper reporting the results of use of *Ergot, Ergotin, and Sclerotic Acid in the Reduction of Enlarged Spleen and in Fibroids of the Uterus.*

DR. C. A. TODD, of St. Louis, read an abstract of a paper entitled

ANTISEPTIC TREATMENT OF SUPPURATIVE OTITIS BY THE "DRY METHOD."

It consists in this: no syringing is permitted, no drops are instilled into the ear; but all the secretions are gently but thoroughly removed with absorbent cotton, and an antiseptic powder is then applied. This method corresponds with that followed in the treatment of wounds in general surgery. Dr. Todd was the first to publish this method of treatment, in 1880, in a paper read before this Association, after he had thoroughly tested and proved its value by use in his aural clinic at the Missouri Medical College. Dr. Burnett, of Philadelphia, states that the duration of treatment by the two methods as tested in his practice, gives an immense advantage to the dry method. Dr. Todd was the first to urge the use of the highly soluble borax as an antiseptic powder, the other antiseptics in vogue being apt to remain undissolved in the ear, and so to cause inconvenience or even positive danger.

The following papers were then read by title: *Report on Malarial Diseases in Children*, by J. P. KINGSLEY, M.D., of St. Louis; *Intestinal Obstruction*, by J. GEIGER, M.D., of St. Joseph; *Report on Railroad Injuries*, by F. M. JOHNSON, M.D., of Kansas City.

The usual votes of thanks were passed.

The *President-elect*, DR. GREGORY, having been called away by a telegram, the *First Vice-President*, DR. WILLIAMS, was escorted to the Chair, and was welcomed in appropriate words by DR. GORE, the *retiring President;* and the Association then adjourned.

MEDICAL SOCIETY OF THE STATE OF WEST VIRGINIA.

Sixteenth Annual Session, held at Grafton, May 16 and 17, 1883.

(Specially reported for THE MEDICAL NEWS.)

FIRST DAY, MAY 16TH.

THE Medical Society of West Virginia convened in sixteenth annual session in the Court House in Grafton at 2 o'clock, the *President*, DR. B. W. ALLEN, of Morgantown, presiding.

DR. W. L. GRANT, *Chairman of the Committee on Arrangements*, made an address of welcome on behalf of the Committee, and Hon. John W. Mason, on behalf of the Mayor and citizens of the city, welcomed the Society to Grafton.

The following gentlemen presented credentials as

FRATERNAL DELEGATES

from the societies named: Drs. H. G. Landis and J. F. Baldwin, of Columbus, from the *Central Ohio Medical Association;* Dr. R. B. Stover, of Richmond, from the *Virginia State Medical Society;* and Dr. David Little, of Lebanon, O., from the *Ohio State Medical Society.*

The first *Vice-President*, DR. GRANT, of Grafton, was called to the chair, and DR. ALLEN then delivered

THE PRESIDENT'S ADDRESS,

in which he discussed the Code of Ethics, and the advisability of establishing a medical department in the State University.

The following gentlemen were elected

NEW MEMBERS:

Drs. Reed M. Baird, C. M. Frissell, J. H. Silbey, I. P. Birney, of Wheeling; T. F. Lanham, Newbery; J. L. Nixon, Flemington; C. O. Henry, Shinnston; J. C. Lawson, Bridgeport; Geo. L. Bomberger, Iron Dale; and J. I Warder.

THE SECRETARY'S REPORT

showed the Society to be in a flourishing condition, and increasing in membership, which now numbers one hundred and seventeen.

THE REPORT OF THE TREASURER

showed the Society out of debt, and a balance of over one hundred dollars in the Treasury.

From the

COMMITTEE ON CLIMATOLOGY AND EPIDEMICS,

DR. R. W. HALL, Chairman, presented a report, briefly reciting facts in regard to the prevalence, in

different parts of the State during the year, of pneumonia, influenza, parotitis, diphtheria, scarlet fever, typhoid fever, variola, and other diseases. Of *variola*, the report says: "It made its appearance in Berkely County, but owing to the prompt action of the State Board of Health, assisted by the Mayor of Martinsburg, the County Court, together with the intelligent aid of the physicians of the county, the disease was effectively quarantined, and only five cases occurred. Thus were the people saved, by these guardians of the public health, from an epidemic of smallpox that would doubtless have cost the State more in treasure alone than the maintenance of a health board for years." . . . "An epidemic of this disease is now raging in Mercer and adjoining counties. A tramp, infected with the disease, was the means of originating the first case. This was supposed to be varicella by the physician, who had never seen a case of smallpox. No attempt at isolation was made. The attending physician contracted the disease. The patient died, and the funeral was public and largely attended. Thus the disease was spread, and ten deaths had occurred at last report. The State and local Boards of Health are using every effort for the suppression of the disease, but not much progress has thus far been made."

He also spoke of *Typhoid Fever Epidemic in Marion County*. There were about two hundred cases, with a mortality of twelve per cent. The history of the disease as it occurred in one family deserves mention. Dr. McIntire was called to see a child in a family of thirteen, living at the head of a ravine, in a log house with but one room. The Dr. promptly notified the local board of health, and asked for instructions. The removal of all the children was directed, and the direction given that no one should use the well water, as the well was found to be in a condition to receive all the surface drainage at and above the house. These directions were unheeded. One after another of the family was stricken down, until every child and the father had contracted the disease. Four deaths occurred.

TYPHOID FEVER.

DR. REEVES thought that typhoid fever may arise *de novo*, under favorable conditions. He held that it is decidedly contagious, and cited cases in his own experience to prove the correctness of this position. He gave his recent experience with ergot in its treatment; he had now used it for about three years, and felt quite sure that under this treatment the cases pursued a milder course. High temperature was not so common, nor were hemorrhages so often met with.

DR. STOVER, of Virginia, advocated the use of ergot in this disease, and also in pneumonia. Believes it acts as an antiseptic more rapidly than any other drug. He gives one drachm of Squibb's fluid extract every three or four hours, and has never met with any unpleasant result.

DR. LANDIS, of Ohio, could not accept the theory that typhoid fever is contagious.

DR. JEPSON remarked that three interesting points are presented for discussion. First, may typhoid fever arise *de novo?* From the investigations of the Massachusetts State Board of Health, he was led to conclude that it may, under exceptional circumstances. Second, is it contagious? In a year's experience, through a severe epidemic, in a large general hospital, where fever patients were not isolated, not a physician, nurse, or patient with other disease, contracted typhoid. This is a common observation. We seldom see two cases in same family. When we do, we always have other means of accounting for the existence of second or third cases. All use the same water, all subject to same emanations from decomposing discharges. He believed that the excreta became poisonous by decomposition, and if a suitable nidus is found for the poison it may again enter the system. He accepts the theory that the disease should be classified as miasmatic-contagious. Third, as to the ergot treatment, so highly lauded, he would say that a very large experience only could determine the value of any remedy. In four years (1878–1882) he had not lost a single patient from typhoid fever. He began to think that he had found a good way to treat this disease. In the next few months, however, he had lost five cases, when he concluded he did not know any more about its treatment than other physicians.

DR. LAZZELL, who has had an unusually large experience in this disease, believed it to be at least communicable; he did not care whether you call it contagious or not. He cited some interesting facts observed during an epidemic in the country, where, he stated, every individual who had visited a certain house where typhoid existed, contracted the disease, and nobody had it who remained away, unless they came in contact with other patients.

DR. BALDWIN, of Ohio, advocated the possible *de novo* origin of the disease. He believed that the previous existence of a case was not necessary, as a man may contract gonorrhœa from a menstruating woman, and afterwards communicate virulent gonorrhœa to another woman. So, he thought, may typhoid fever arise *de novo*, and afterward be communicated by contaminated drinking water. He did not believe the disease ordinarily contagious, but was not quite prepared to say that very malignant cases did not sometimes prove so. As to treatment, he knew many cases would recover without treatment, or with any plan of treatment, or even in spite of treatment.

He was not in the habit of giving much medicine, but proper feeding and nursing were the main elements in the management of this disease. We often speak of "curing" our cases, but he preferred to use the term in its original sense of taking care of, and not in the sense of *making well*. With the former meaning we doubtless do cure many of our cases.

DR. CARPENTER emphatically protested against these "do-nothing doctrines" in the treatment of disease. We have many positive remedial agents, and they may be used with decided benefit in the treatment of the disease under consideration. The prevailing opinion seemed to be that the disease may arise *de novo;* that it is not contagious in the common acceptation of that term; that many cases recover with but little treatment except the most careful nursing and attention, but that bad symptoms may be often successfully combated with proper medicines.

DR. J. E. REEVES then introduced the following resolutions regarding

THE ARMY MEDICAL MUSEUM AND LIBRARY:

Whereas, The collections known as the Army Medical Museum and the Library of the Surgeon-General's office, located in Washington, D. C., are recognized as among the most complete and valuable of their kind in the world; and as their practical usefulness has been abundantly demonstrated by the interest with which they are regarded by the medical profession, both at home and abroad; and

Whereas, By reason of the insecurity and unsuitability of the building in which they are now placed, they are in constant danger of damage or destruction, from which would ensue irreparable loss; therefore

Resolved, That in the opinion of the Medical Society of the State of West Virginia, the inestimable value of these collections demands from Congress such fair consideration of the merits involved, as will secure an appropriation of sufficient amount to provide a fire-proof building of adequate size and suitable construction,

for the present and future uses of the Museum and Library.

Resolved, That the Army Medical Museum and Library of the Surgeon-General's Office, are inseparable in object and interest, and only capable of the greatest usefulness when under one control and management; that this Society views with regret and disfavor, any attempt to separate the two. Dismemberment must result in injury to both.

Resolved, That Congress would meet the wishes of the medical profession of the United States, by appropriating suitable sums of money for the support, care, and increase of these collections; viz., not less than ten thousand dollars annually for the library, and five thousand dollars for the museum.

Resolved, That the work now in progress under the direction of the Surgeon-General of the Army, entitled "An Index Catalogue of the Library of the Surgeon-General's Office," is also one in which the medical profession of the United States is greatly interested, and should receive the substantial aid and encouragement of Congress, with a view to its speedy and certain completion.

Resolved, That a copy of these preambles and resolutions be forwarded to each senator and representative of our State, requesting his special aid and coöperation in the matters herein specified.

These resolutions were unanimously adopted.

SECOND DAY, MAY 17TH.—MORNING SESSION.

DR. D. PORTER MORGAN presented a preamble and the following resolution:

Resolved, That this Society elect annually three members, who shall constitute a COMMITTEE ON PUBLICATION, whose duty it shall be to associate with themselves an editor. This Committee and editor shall publish a quarterly medical journal, under the auspices of this Society (and, if practicable, in conjunction with the State Board of Health), to be styled ———. This Committee and editor, in addition to publishing through the different numbers of the year the approved papers read before this Society, may insert original articles, selections, etc.

After a brief discussion, not altogether favorable, on motion of DR. JEPSON, the preamble and resolution were referred to the Committee on Publication, with instructions to report on the subject at the next annual meeting.

DR. A. F. STIFEL, on behalf of the

COMMITTEE ON THE BROCK PRIZE,

reported that no medical paper had been presented to the Committee.

DR. JOHN FRISSELL, of Wheeling, read the report of *A Lithotomy;* and also read a paper entitled

HEALTH: HOW TO BE ACQUIRED, AND HOW TO BE PRESERVED.

A large part of the paper consisted of a treatise on tobacco, its history, properties, and evil effects on those using it habitually. As the paper contained many facts that might be of use to the people, it was, on motion of Dr. Wilson, referred to the State Board of Health, to be printed in their *Report*.

DR. VANKIRK, of Grafton, presented the following preamble and resolution regarding the

NATIONAL BOARD OF HEALTH,

which were adopted without discussion.

Whereas, The National Board of Health, by its efficiency and faithful discharge of official duty, has won the confidence and endorsement of the most expert sanitarians, both in this country and Europe, and of the medical profession generally in the United States; and

Whereas, This Society deems it of the greatest importance that the strong arm of the general government shall be exercised to prevent the introduction of contagious and infectious diseases into the United States from foreign ports, and their spread from State to State; to coöperate with and aid State and municipal boards when such domestic authorities are unable to control or stamp out epidemic diseases among the people; therefore,

Resolved, That this Society requests the senators and representatives in Congress from West Virginia to use their influence to accomplish such legislation as will secure the perpetuity and usefulness of the National Board of Health in preventing the importation of foreign pestilences and their spread among the people; to coöperate with and aid State and municipal boards of health when such boards are unable to control and suppress pestilences which are afflicting and killing the people; to encourage investigations concerning the sources or causes of diseases among the people; and insanity as a disease, and the duty of the medical profession of the State concerning its management. Clothe the central power and authority with a sufficient appropriation of money to enable it to discharge the important trusts committed to its care, and in a manner creditable alike to the general government and the medical profession of the United States.

DR. LAZZELL, of Fairmount, presented a brief report on *New Remedies*.

The following papers were read by title:

Cholera Infantum and its Sanitary Management, by DR. T. O. EDWARDS, of Wheeling.

Anomalous Cases of Labor, by DR. C. F. ULRICH, of Wheeling.

DR. R. W. HALL, of Manington, presented the

REPORT OF A CASE OF PERITONEAL HÆMATOCELE,

in which he drew off, by aspiration, ninety-six ounces of fluid, resembling prune-juice in color, and having quite an offensive odor. The patient expressed herself as greatly relieved. All the tenderness and pain that had previously existed vanished as if by magic. The patient, however, soon had general peritonitis, but finally recovered, and now enjoys good health.

A paper on the *Germ Theory of Disease*, by DR. E. C. MYERS, of Wheeling, was read by title.

DR. D. PORTER MORGAN read a paper on the

ABUSE OF ERGOT IN OBSTETRIC PRACTICE.

He urged that we should give ergot in labor cases: 1. Never till the uterus is thoroughly dilated or dilatable, the perineum thoroughly relaxed, and not unless the pelvis is of normal shape; and it is better not given even then.

2. Not until the head has passed the perineum, and continued inertia exists.

3. To secure contraction in post-partum hemorrhage, but then not until the uterus is emptied of placenta, coagula, etc., by other means. Even in such cases continued pressure of fundus after Credè for expelling placenta is better, and the intra-uterine injection of hot water is superior to ergot in controlling hemorrhage, and is not attended with the same unpleasant effects. Quinia and the abdominal bandage will overcome uterine atony in almost all cases much more certainly than ergot, and we possess in the hand a safe, rational, easy, ever-ready remedy to be used in the manner already mentioned.

Finally, it is very questionable whether the risks to both mother and child from the use of ergot do not more than counterbalance any advantages attending its use. It were probably better had it never been given in labor, at least before the uterus was emptied.

DR. LANDIS, Prof. of Obstetrics in Starling Medical College, was invited to speak on the subject. He said

he had at one time resolved to attend one hundred consecutive obstetrical cases without the use of ergot, carefully watching the results. Towards the completion of the series, two cases occurred, serving to show how often we may be mistaken as to what we suppose to be the action of ergot. In the first, arterial action was so imperfect, and he was so weary of the case, that he sent for ergot, resolving to break over his rule. Before the ergot arrived, however, active uterine pains set in, and continued so violent that the fœtus was at once expelled, and the labor terminated. Had the patient taken a single dose of the ergot, he would have been quite certain that the active contractions were the result of it. In the second case, where hemorrhage existed, and the usual means at hand failed to check it, he reasoned, "Now, if this patient dies, I will probably be criticised for not using ergot," and a dose of fluid extract was administered. He was confident it had not reached the bottom of the woman's stomach until she began to vomit, and, at the same time, active uterine contractions set in, which at once put an end to the hemorrhage. Now, he was quite sure that, in many cases, tonic contractions of the uterus come on during labor without any obvious cause, and sometimes after ergot has been given, but entirely independent of any so-called oxytocic effects of that drug. More frequently ergot excites uterine action by producing nausea, which all physicians are glad to see in atonic conditions of the uterus, because they know it is generally followed by active contractions. On this principle he had no doubt ipecac acts, this drug having recently been lauded as an oxytocic.

Remarks were added by Drs. Gregg, Morgan, and Stover, of Virginia, all discouraging the too frequent use of ergot.

DR. CARPENTER, of Moorefield, read a paper entitled

INSANITY AS A DISEASE, AND THE DUTY OF THE MEDICAL PROFESSION OF THE STATE AS TO ITS MANAGEMENT.

DR. BALDWIN, of Ohio, coincided largely in the views of the writer. Asylum statistics were very deceitful. Cases were reported as cured which found their way back, only to be reported cured again; thus adding to the number of "cured" in the statistics, no cure at all having been brought about. He did not believe much in the possibility of curing the insane, except such functional cases as depended upon some disease elsewhere than in the brain as puerperal insanity, etc. These may be cured, but not five per cent. of the cases of genuine insanity are in his opinion curable. He referred to Spitzka's criticism of asylum superintendents, and agreed with him that these men, while enjoying so many opportunities, had done almost no scientific work. Much more in this direction had been done by men having no connection with asylums than by the medical officers of those institutions.

Remarks were also made by Drs. Reeves, Howell, and Kunst, the latter formerly an officer of the State Asylum. He thought Dr. Carpenter had done the institution injustice in his statistics. During his connection with the institution, they had never included among the cured the same patient twice in the same year.

As a result of this discussion, the following resolution, offered by DR. HOWELL, was adopted:

Resolved, That a committee of seven, with Dr. Carpenter as chairman, be appointed by the President, whose duty it shall be to collect statistics and general information relating to the management of the insane, and report to this Society at its next annual meeting.

The following were appointed members of the Committee: Dr. G. H. Carpenter, of Moorefield, *Chairman;* Drs. A. Howell, of Clarksburg; G. B. Moffett, of Parkersburg; A. Gittings and A. H. Kunst, of Weston; A. F. Stifel and J. B. Reed, of Wheeling.

The following, offered as

AN ADDITIONAL BY-LAW,

by DR. JEPSON, was unanimously adopted:

No member shall occupy more than twenty minutes in the reading of a paper before this Society. If the paper prepared is too lengthy to be read within this limit, it may be read by abstract, the paper in full being referred.

Several other unimportant amendments were made in the Constitution and By-laws.

DR. MORGAN, of Clarksburg, presented the following resolutions regarding

THE NEW YORK CODE.

Whereas, The medical profession of West Virginia views with deep concern and regret the confusion and discord which have resulted in the State of New York from the action of the State Medical Society in renouncing its allegiance to the Code of Ethics of the American Medical Association, under which all State and other auxiliary societies have so long and harmoniously worked together for the common good; and

Whereas, Certain medical journals and specialists, under the specious pleas of "liberality," "humanity," and an advancing civilization (?), have used, and are still using every effort to bring about and maintain such a degree of opposition to the National Code as shall completely separate the said State Medical Society of New York from affiliation with all loyal organizations in other States, thus rendering it independent of, and antagonistic to, the American Medical Association; therefore be it

Resolved, That the Medical Society of the State of West Virginia again declares and reaffirms its willing allegiance to the time-honored National Code of Medical Ethics as the great common law, and the only safe and proper guide for the physician in the midst of the conflicting interests with which he is beset in daily practice, and in his intercourse with his Fellows.

Resolved, That the delegates from this Society to the American Medical Association, at its forthcoming meeting, be and they are hereby instructed to resist, by their votes and influence, all attempts which may be made to change or modify any of the provisions of the Code, or to in any other way compromise the dignity, high standing, and influence of the profession.

Resolved, That this Society recommends to the medical profession in West Virginia that they support by their subscriptions only such medical journals, recommend their patients only to such specialists, and direct their students only to such medical colleges, as have shown by their unequivocal attitude their appreciation of the demands of true humanity, their recognition of the pure and unselfish aspirations of our calling, and their loyalty to the high and noble interests of rational medicine.

Resolved, That a copy of these preambles and resolutions be forwarded to the permanent Secretary of the American Medical Association.

This resolution was unanimously adopted.

On motion of DR. LAZZELL, the Secretary was directed to purchase twenty-five copies of the Code of Ethics for the use of new members.

DR. S. L. JEPSON, of Wheeling, read a paper, entitled,

PUERPERAL FEVER, WITH SPECIAL REFERENCE TO ITS TREATMENT BY INTRA-UTERINE ANTISEPTIC IRRIGATION.

This was discussed by Prof. Landis and Dr. Morgan.

The Society then went into the

ELECTION OF OFFICERS,

which resulted in the choice of the following:

President.—DR. A. GERSTELL, of Keyser.

Vice-Presidents.—1st. DR. C. T. RICHARDSON, of Charlestown; 2d. DR. A. T. STIFEL, of Wheeling; 3d. DR. D. P. MORGAN, of Clarksburg.

Treasurer.—DR. J. A. CAMPBELL, of Wheeling.

Secretary.—DR. S. L. JEPSON, of Wheeling.

Board of Censors.—DRS. A. H. KUNST, G. B. MOFFETT, GEO. BAIRD, J. B. REED, J. E. REEVES, J. N. BROWNFIELD, A. H. THAYER.

Clarksburg was chosen as the next place of meeting.

The Society then adjourned.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Fifth Annual Congress, held in New York, May 21, 22, and 23, 1883.

(Specially reported for THE MEDICAL NEWS.)

MONDAY, MAY 21ST.—FIRST DAY.

MORNING SESSION.

THE Fifth Annual Congress of the American Laryngological Association was called to order in the Hall of the New York Academy of Medicine, at 10 o'clock, by GEORGE M. LEFFERTS, M.D., PRESIDENT of the Association.

THE SECRETARY, DR. D. BRYSON DELAVAN, called

THE ROLL,

the following Fellows responding to their names:

Morris J. Asch, of New York; F. H. Bosworth, of New York; J. Solis Cohen, of Philadelphia; Wm. H. Daly, of Pittsburg; T. A. DeBlois, of Boston; D. B. Delavan, of New York; F. Donaldson, of Baltimore; J. H. Douglass, of New York; W. F. Duncan, of New York; L. Elsberg, of New York; T. R. French, of Brooklyn; U. G. Hitchcock, of New York; F. H. Hooper, of Boston; E. F. Ingals, of Chicago; F. L. Ives, of New York; W. C. Jarvis, of New York; S. Johnston, of Baltimore; R. H. Kealhofer, of St. Louis; F. I. Knight, of Boston; S. W. Langmaid, of Boston; G. M. Lefferts, of New York; R. P. Lincoln, of New York; G. W. Major, of Montreal; E. C. Morgan, of Washington; D. N. Rankin, of Allegheny; Beverley Robinson, of New York; J. O. Roe, of Rochester; Carl Seiler, of Philadelphia; A. H. Smith, of New York.

THE CHAIRMAN invited ex-Presidents of the Association to occupy seats upon the platform.

THE PRESIDENT then delivered his

ANNUAL ADDRESS.

After thanking the members for the honor conferred in his election as presiding officer, and bespeaking their assistance in the performance of his duties, he followed a duty sanctioned by custom by making some comments and offering a few suggestions. The status of the present Congress was the first subject of congratulation. Never before in the history of the Association had the annual gathering been so numerous. Never before had the number of essays been so large. At the first Congress they numbered fourteen, at the second eight, at the third fifteen, at the fourth eleven, and to-day they have swelled to the number of twenty-three—within one of fifty per cent. of the whole membership. Never before have the subjects chosen covered so wide and varied a ground, nor been of as great interest. Do not these facts speak for the vigor, for the vitality of our organization? Do they not show an increased and increasing interest in our work, and in each other? I hold so; and I congratulate you that it is so; and I congratulate myself, with a just and pardonable pride, that it has been under my leadership; that you have so well rallied about me, in my earnest aim to make the present a memorable occasion in our history.

Our constitutional limit of membership is fifty; to-day, after a short life of five years, that limit has been, or will be in a few moments, reached. Our ranks are full, our number to-day complete. Here, again, a subject for self-congratulation presents itself; success has crowned our efforts to make our young Association a living and lively power among American laryngologists; of its enviable reputation abroad I do not speak.

In order to provide for those who stand waiting for entrance, he deprecated increasing the constitutional limits of Fellowship, and suggested in its place a process of elimination, and substituting for a few drones in the hive able and active men, who are anxious and willing to assume these unprofitable Fellowships.

After referring to the annual volume of transactions, the visible sign of growth and importance of the Association, he referred to the incidental and social benefits, both personal and professional, derived from an annual gathering, as "a periodical taking stock of the gains of science in our department, of improved appliances, of more accurate means of diagnosis, and of more efficient means of treatment." He said, "We seek to assimilate to ourselves whatever is of value in the past or in the present, especially in the realms of our science and art."

"We are here then to-day, my colleagues, to spread the truths we know, and learn from others the truths they have to tell. We are here to give our knowledge freely, and to receive from others as freely the knowledge they have to bestow, and in the giving, as well as in the receiving, we shall increase our own store; *docendo discimus.*

"We are here to meet each other socially, to promote kindly feeling, to renew old friendships, and to lay the foundations of new, and, by personal intercommunion, to consolidate the bonds of that professional brotherhood of which we are all so justly proud.

"Gentlemen, fellow-workers, in promoting these good works, I bid you God-speed.

The CHAIRMAN called attention to a provision of the by-laws, limiting the time for papers to twenty-five minutes. He suggested the passage of a resolution, limiting the time devoted to discussion.

DR. W. F. DUNCAN offered the following resolution, which was adopted:

Resolved, That each gentleman taking part in the discussion shall limit himself to five minutes' time, and shall not speak again during the same discussion, except by universal consent of the members present.

THE FIRST VICE-PRESIDENT, DR. CARL SEILER, was called to the chair.

THE PRESIDENT, DR. GEORGE M. LEFFERTS read a paper entitled

NEW FACTS IN LARYNGOLOGY.

In using the term *new*, to characterize the facts to which Dr. Lefferts called the attention of the Congress, he was mindful of the aphorism, that there was "nothing new under the sun," and would perhaps, in the presence of an audience of experts, be obliged to substitute the term *fresh;* both adjectives would be appropriate, as far as he personally was concerned, for never until recently had he met with a case which presented the peculiar phenomena that he would attempt to describe; his study of the question likewise showed him that little concerning the matter existed in the literature of the day, and even that was indefinite; seven cases only were upon record. He believed the field opened

up then for the labor of the Congress in this special question alone, was large, fertile, and he thought richly worthy of cultivation.

A gentleman is sitting at his dinner-table surrounded by friends; suddenly he ceases his conversation, endeavors to check a short cough, and the next instant falls from his chair to the floor unconscious, cutting his forehead as he plunges head-foremost upon the latter; almost immediately he arises, resumes his seat, and the conversation at the point where it was broken off.

Can any possible relation be traced, Dr. Lefferts now asked, between so slight a cause as the cough and so marked an effect as the fall? This was the question of the paper.

The patient was a young, strong man, free from any abnormality of either heart, lungs, or kidney. The attack here described was not the first that he has had. Several have occurred during the past eight years; he now lives in dread of a sudden fall. Very frequently, attacks of partial unconsciousness, always preceded by the same paroxysmal cough, have occurred; they last but a few seconds, are preceded by a blurring of vision, with dizziness or vertigo, and pass away instantly, leaving him clear-headed and bright. He has an incomplete history of hereditary neurosis. There is no evidence of any convulsive movements during the attack. The latter are always ushered in by the tickling in the larynx and violent cough. The face becomes suffused. In the worst he falls without cry, but rises immediately without confusion of ideas, and without remembrance of what has taken place during the brief unconscious interval. The less serious varieties of the attacks were then described by the writer of the paper.

An examination of the patient's throat showed little that was abnormal.

Dr. Lefferts had seen one other instance of the same affection, and the two constituted his experience of it. The second case resembled the first in all its main features, but was less severe, and had lasted a shorter time. The details were given.

After summing up the literature of the affection, and showing that Sommerbrodt was the first, in 1876, to describe a somewhat similar instance, dependent, in his case, probably upon the presence of an intra-laryngeal tumor, Dr. Lefferts reached the question of whether the series of phenomena that he had described would allow of his classing his cases as ones of "laryngeal vertigo," such as were described by Charcot. The question was then raised whether the name given to them by Charcot correctly described and explained the phenomena. Charcot holds that the curious symptoms take their origin in a peculiar irritation of the centripetal laryngeal nerves; that the "laryngeal vertigo" is, in many respects, to be compared with the vertigo met with in "Ménière's disease."

But does it not differ essentially from this affection in being attended by attacks of complete unconsciousness? asked the lecturer. How account for the convulsive movements that have been present in some of the reported cases? How reconcile the experience gained by the experiments of Féréol in the study of the laryngeal symptoms of locomotor ataxia with Charcot's hypothesis. Organic irritation of the laryngeal nerves *may* cause violent, powerful, paroxysmal cough, but the cases are not necessarily attended by loss of consciousness. Even direct violence to a nerve needs to be *excessive* in order to produce the latter condition.

Dr. Lefferts was therefore inclined to accept the theory of Dr. Grey, as laid down in his recent valuable essay, to which he was indebted for much information, that the disease in question was a form of epilepsy—using the term in its most catholic sense. The personal or hereditary, neurotic or epileptic history—complete or incomplete—obtainable in the majority of the reported instances, was a strong argument in favor of this view. But it was fair to state that it differed from the real disease in more than one important particular; notably in being readily amenable to treatment.

After a few further remarks, the question was submitted to the Congress for discussion, Dr. Lefferts requesting that the latter might more especially be directed to the matter of etiology.

DR. L. ELSBERG said that he scarcely felt able to take part in the discussion, and would merely refer to one point. He did not quite agree either with Charcot, in regarding the disease as vertigo, or with Grey, in considering it as an epilepsy. He considered it simply as a form of adductor spasm, a peculiar spasm of the intrinsic muscles of the larynx. At the last meeting of this Association, he called attention to several cases of this kind which Hack had reported; in one or two of which there were some symptoms which Charcot had alluded to, with loss of consciousness, vertigo, etc. He simply rose to make this statement, that he regarded these cases as instances of adductor spasm.

DR. KNIGHT suggested that the theory that the phenomena were due simply to the disturbance of the respiratory function, or as supported by the fact, well known, that temporary unconsciousness may be produced by rapid respirations, as in the practice of auscultation; in fact, anæsthesia for operation was sometimes so produced before the days of chloroform and ether.

DR. MAJOR remarked that though not prepared to discuss so abstruse a phenomenon as that propounded by Dr. Lefferts on purely scientific grounds, still on general principles he thought it well not to lose sight of the fact that such a condition might probably be considered an epileptic aura; such peripheral irritation occurred elsewhere, then why not in the larynx? At the same time, he did not seek to diminish the interest of the subject to the pure laryngologist.

DR. S. JOHNSTON thought the suggestion offered by Dr. Knight a good one, having personally experienced an attack of vertigo from rapid respiration.

DR. INGALS suggested that the brief and sudden loss of consciousness was similar to that of pseudo-apoplexy of fatty degeneration of the heart.

DR. LEFFERTS, in closing the discussion, remarked that it would seem from what has been said that the whole subject is, as he had said, involved in doubt and obscurity. Of course, it is very easy to construct theories to account for the phenomena presented by these patients. He was inclined to believe that it is one of the various auræ of epilepsy, commencing in the larynx. The subject is a comparatively new one in laryngology, and affords a wide field for future investigation and study, which he commended for the further consideration of the Association.

A COMMON FORM OF VOCAL DISABILITY RESULTING FROM PATHOLOGICAL PROCESSES.

S. W. LANGMAID, M. D., of Boston, called attention to a common form of vocal disability resulting from pathological processes, the phenomena being used to demonstrate the falsity of one system of voice training. He had observed a class of patients who are in the habit of making considerable use of their voice, who complain that at a certain point in singing the scale a break occurs in their voice; below this their normal tones are preserved. He attributed this condition to fatigue of the vocal apparatus, caused by fatigue following over-exertion. It not infrequently results from sudden cessation of singing after excessive use of the voice, and is more likely to occur in those filling a leading *rôle* than in the subordinate parts. It may be

gradual in its onset, or may come on suddenly while on the stage. On examination, in addition to some injection of the mucous membrane over the cords, there is a relaxation of the vocal cords, due to paresis of the sphincter muscles of the glottis, including the tensor of the cords. The laryngoscopic appearances are those of fatigue, so well described in Cohen's work. The only fact to which he directed special attention, is that in examining the vocal apparatus, and asking the patient to sing the scale from below upward, he had noticed that on reaching a certain point in the scale there was a sudden relaxation of the cords, accompanied by a lowering of the voice, in a soprano at the ninth of the scale or the key of C; and in low voices at the seventh. It is a peculiar fact that this is just where the so-called change in the register occurs. The practice of falsetto upon these notes will in time produce the same pathological changes in the larynx as we see in cases of fatigue of the vocal organs.

Dr. Wm. H. Daly said that two cases had come under his notice within the last three months, illustrating the condition so ably described by Dr. Langmaid. The first was a former patient of Dr. Langmaid, and was referred back to him for treatment. He was a leading member of an opera company. He had a well-developed larynx, and there was no abnormality of the nasal chambers, certainly no enlargement of the pharyngeal tonsil. He was a very conscientious singer and his *confrére* was a very lazy one, so that he was forced to make extra effort in order to sustain his part to the best of his ability, and sometimes to his own disadvantage. He was suffering very much when he came to Pittsburg, so much so that he was afraid to undertake his *rôle*, as his voice suddenly failed on reaching a certain pitch. After a very careful examination of the case with the laryngoscope, and of his general physical condition, an opinion very much like that of Dr. Langmaid was expressed—that he was suffering from fatigue of the laryngeal muscles. He was directed to rest his voice for a time; either withdrawing entirely from singing, or by practising the parts of his colleague.

The next case was that of Miss A., an eminent opera singer, whose voice suddenly failed her in Pittsburg. Upon examination, a patch of Pittsburg soot was seen upon the right vocal cord, covering about one-third of its surface. When this was removed, a hyperæmic patch was discovered. She had been singing for many nights and had been over-worked. After the foreign substance had been removed, there was observed a relaxation of the muscles which were called upon in the formation of the upper notes. She greatly improved under rest and tonics.

Cases of this character require more than local treatment—ergot, nux vomica, and other nerve stimulants will restore vital action and will assist, with rest, in re-establishing a healthy action.

Dr. George W. Major said that the last patient mentioned by Dr. Daly had also been under his care last spring. She had been very much over-worked, having sustained the part of her tenor, suffering a severe strain with complete shutting off of sound. A condition resembling paresis of the arytenoid muscle was discovered, with slight hyperæmia. Rest was advised, but the advice was not followed.

In closing, Dr. Langmaid said, in reply to Dr. Seiler, that it seems not unlikely that the occurrence of hypertrophied pharyngeal tonsils might easily help to produce such a disturbance in the production of tone as to lead the singer to adopt some unnatural method of singing which would be likely to produce fatigue of the vocal organ. He agreed that treatment by strychnia, galvanism, and other means is to be used in these cases. He has never used ergot in this condition.

Since reading the paper he had been informed by Dr. Elsberg that Mandl has written upon the subject treated in his paper. He was quite unaware of this, and should be glad to compare Dr. Mandl's observations with his own.

Afternoon Session.

A paper on the

destruction of nasal polypi by chromic acid

was read by Frank Donaldson, M.D., who said that the object of treatment in cases of mucous polypi is to remove the growth with as little discomfort as possible, and to prevent their return. Of the three methods in use—evulsion, abscission, and the electric cautery, each had its advocates and its advantages, and each its disadvantages. Evulsion causes pain, and is often inefficient to prevent their return; the removal by the snare or wire loop is open to the same objection, unless the origin of the growth is cauterized, or part of the underlying structure, including the bone, is removed, as recommended by Mackenzie. Of the caustics, in his experience, chromic acid deserved the preference. His manner of employing it is to protect the surrounding mucous membrane with a lead solution, and part of the paste is then taken up on a glass rod and buried in the polyp, which shortly afterward dries up, and is easily removed with the forceps or snare. With chromic acid we can touch the exact point of origin of the growth; and it is useful in both forms of polypi, in gelatinoid and adenomatous. In the fibrous polypi it is less efficient, because they extend frequently to the naso-pharyngeal cavity. It is not intended to substitute chromic acid for surgical procedures, but it is effective as an aid to them, facilitating their action by destroying the substance of the neoplasm, by making the operation less painful, less bloody, and by supplementing their action in destroying the insertion of the growth, and thus preventing their reformation.

Dr. Wm. C. Jarvis said that a case had come under his observation which offered an excellent opportunity for the study of gelatinoid polypi. In this patient a markedly deviated septum had closed the superior meatus of the left nostril, causing a severe hemicrania, worse in damp weather. Believing that the headache was dependent upon the malformation, he removed the deviated tissue and found the roof of the nose occupied by a number of bead-like polypi. These embryonic polypi account for the return of the growths after removal. He believed that his écraseur, by nipping off a piece of the mucous membrane, prevented the return of growths removed by this method.

The embryonic cluster of polypi will account for their reappearance by space being offered for their development. Chromic acid is desirable to shrivel up these young polypi, but the écraseur should be always used for the larger growths.

Dr. Seiler said that he had some remarks to make in regard to the pathology of polypi. He had examined a large number of growths microscopically, and had found them to consist of localized hypertrophies of the mucous membrane which had undergone myxomatous degeneration. He had therefore thought that recurrence was not due to regrowth from the pedicle, but due to new formation of polypoid growths caused by irritation, and that if all polypi were removed there would be no recurrence. He had found the wire snare of the Jarvis pattern to be superior to chemical escharotics, and had used the galvano-cautery, if necessary, to destroy the stump, as it was less painful and gave rise to less irritation when properly used than any other caustic he had ever used.

Dr. W. F. Duncan said that he had treated a large number of cases of nasal polypi, and very much to his

regret had noticed a regrowth or redevelopment of the polypi, under all forms of treatment, except where a part of the underlying turbinated bone had been removed. Chromic acid he had found useful to produce shrinkage of the growths, thus giving more room for the subsequent operation, and also in reducing the danger of bleeding after removal. The point which he especially wished to make is this, that after any operation, except the one mentioned, for the removal of gelatinoid polypi, they would be likely to return in the course of four or five years; he believed that they would return in eighty per cent. of the cases thus treated. He stated that the only method in which there is no recurrence is that advocated by Morell Mackenzie and Professor Gross, of removing a portion of the turbinated bone with the base of the polypi.

Dr. Daly inquired if the application of the chromic acid and removal of the growth were accomplished at one sitting.

Dr. Donaldson replied that they were.

Dr. Daly said that this would remove one objection to the treatment. He had no personal experience with the treatment as advocated by the lecturer; but it had always appeared to him that any treatment except that of prompt removal was a waste of time. He had used chromic acid, in fine crystals, applied with a copper curette or spoon to naso-pharyngeal growths, with much satisfaction. He had also used acid nitrate of mercury and glacial acetic acid, and had been much pleased with them. He did not think it made a great difference which form of caustic is applied, the effect is about the same.

Dr. Donaldson, in closing the discussion, said that he had used all the other caustics, but infinitely preferred the chromic acid; it acts more promptly, and is more efficient. Ordinarily, he asks the patients to report themselves once or twice afterward, so as to see that the growth had been entirely removed. He did not say that the pedicle of the growth cannot be removed with the snare, but merely that the chromic acid was more convenient to use than the snare.

Dr. F. I. Knight, of Boston, read a paper on

CHOREA LARYNGIS,

in which he recognized three classes of cases which had been reported under this head.

1. Those cases in which not only the adductors of the larynx, but also the expiratory muscles of the chest and abdomen are affected. This is the most common class, and includes most of the cases. The "barking" cough comes under this head.

2. Those cases in which the laryngeal muscles have been affected without any affection of the expiratory muscles. In this connection Dr. Knight reported an unique case of rhythmical chorea of the adductors, associated with rhythmical chorea of the levator palati.

3. Cases in which the expiratory muscles alone have been affected.

Dr. Knight considered that in our present knowledge of functional neuroses, instead of excluding cases which gave evidences of general chorea, or even of hysteria, we should look upon these manifestations as confirming our diagnosis; as all the functional resources seem closely allied, and that the present state of our knowledge would allow us to apply the term "chorea laryngis" to any involuntary clonic spasm which occurs in the larynx.

Dr. Langmaid said that by Dr. Knight's kindness he had had an opportunity of seeing this case; he was struck by the noiseless, rhythmic movements of the palate and laryngeal muscles. It would seem as though no remedies could be of service if medicine proved useless. In connection with Dr. Morgan's recital of his case, he said that in a similar one, which had already been reported in the proceedings of the Society for Medical Improvement in Boston, it was found that the explosion of sound was always preceded by a slight opening of the mouth. The patient was taught to close the mouth in time to prevent the explosion, and this proved to be completely curative.

Dr. Morgan stated that he had been particularly interested in Dr. Knight's paper, as he had an obstinate case of chorea laryngis associated with movements of expiratory muscle, occurring in a girl ten years of age. There was a barking or crowing cough every five or ten minutes, as also irregular movements of the arm. This cough was absent during sleep; articulation was perfect and general health good; the treatment employed, which has been partially successful, was Fowler's solution of arsenic; galvanism, tonics, etc., had failed to relieve.

Dr. Ingals said that he had, some years ago, seen a patient who presented some of the symptoms mentioned in the paper; there was no spasm of the vocal cords, but there was rhythmic contraction of the levator palati with synchronous clicking sounds, which appeared to be due in some way to the action of this muscle on the orifice of the Eustachian tube. The patient had been sent to him by Prof. E. L. Holmes, of Chicago, on account of the peculiar clicking sounds, and had returned to him for treatment. The result was unknown.

Dr. A. H. Smith referred to a case of spasmodic contraction of the diaphragm lasting several weeks, which he had referred to the same cause, although affecting a different set of nerves.

Dr. Knight inquired if any Fellow had seen a case reported elsewhere of spasmodic closure of the glottis, as he had not been able to find a similar case to his own in medical literature. He was very glad to hear of Dr. Ingal's case.

Dr. E. Fletcher Ingals, of Chicago, read a paper on

THE TREATMENT OF LARYNGEAL PHTHISIS,

in which he said he took up the subject more from a hope of eliciting a discussion than with an expectation of completing it. It appeared to him that there were three prominent indications to be met in the treatment: 1st. To relieve pain. 2d. If possible to cure the disease. 3d. Failing in this, so to modify the course of the affection as to prolong the patient's life. In meeting the indications, pain may be generally relieved by topical applications, even though internal medication is of little avail. The disease may sometimes be cured by combining topical and internal medication, and in some cases by either of these alone. But if cure is impossible, life may be prolonged in most cases, by relieving pain, and enabling the patient to swallow, when otherwise he would die from lack of nutrition.

The reader illustrated his points by six cases, in two of which the internal remedies consisted mainly of the chloride of lime with cod-liver oil, or maltine and alcoholics; but in one, the most important factor in the treatment was removal to the invigorating atmosphere of Colorado. Mildly astringent and antiseptic topical applications were used. The author has also used a combination of morphine, carbolic and tannic acids; the last seeming to prolong the sedative effects of the carbolic acid. This application causes considerable smarting, which, however, only lasts a few minutes, and the painful deglutition was almost entirely relieved. This sedative solution he has also followed by iodoform.

In one case a solution of nitrate of silver was applied to a laryngeal ulcer, followed by a powder of iodoform and boracic acid. A spray of a solution of carbolic acid and sulphate of zinc, āā gr. ij–℥j, was ordered for

home use, and bromide of potassium and tincture of belladonna internally. After two weeks' treatment, the cough was much relieved, but there was only slight, if any, improvement in the ulcers. Full doses of iodide of potassium were also given, with no better result. The patient was then put on grs. x of chloride of calcium in syrup of sarsaparilla after each meal, on which her general condition began to improve, though the ulcer was not perceptibly bettered. Eucalyptol was then applied to the ulcer, with the effect that, in two weeks, it was very markedly improved, and in continuance of this and the internal treatment, the patient made such favorable progress that at present she is doing fairly well. There was a single large ulcer, with no swelling of the ary-epiglottic folds, but the symptoms and history, with the absence of former scrofulous or syphilitic taint left no doubt as to the diagnosis.

Another case, with no bad history, and with extensive superficial ulceration of the ventricular bands, vocal cords and posterior commissure, was put on the chloride of calcium, tincture of iron, with cod-liver oil and alcoholics internally, and the solution of morphia, tannic and carbolic acids, followed by a powder of equal parts of iodoform and boracic acid applied to the larynx. Two weeks later a spray containing bichloride of mercury, gr. $\frac{1}{16}$–$\bar{3}$j, was ordered for home use; in six weeks there was decided improvement in general health, but the ulcers showed none. Eucalyptol was then applied, and under this treatment the ulcers began to improve, and the patient is still getting better. The reader did not hope for a cure either in this or the preceding case, but eucalyptol had given better results than any other topical application.

In conclusion, he thought it well established that: 1. We may meet the first indications for treatment better by topical applications than by any other means, and may expect to give the patients great relief for a considerable length of time. 2. A limited number of cases of laryngeal phthisis may be cured by local and general treatment. 3. In many, even of the fatal cases, life may be prolonged for several weeks by the topical application of remedies which obtund the sensibility of the part, so as to spare the patient the exhaustion incident to the pain and irritating cough, and at the same time allow the ingestion of food.

Dr. Wm. C. Jarvis, of New York, read a paper, entitled

THE HEALING OF ULCERS IN LARYNGEAL PHTHISIS.

He premised his remarks with a reference to the incredulity of the medical profession regarding the cure of laryngeal phthisis. This was in part due to fragmentary histories of cases reported, insufficient evidence, and claims for cure based upon peculiar methods of treatment. The history of a case was recited in which the phthisical ulcers had been entirely healed. The evidence of physicians and specialist from whence the case came, demonstrated conclusively advanced laryngeal phthisis. The lungs had been examined by experts, and coexisting pulmonary phthisis discovered. The treatment was explained in detail. It consisted locally in the frequent use of fine, unirritating sprays; atomized alkaline fluids were employed for cleansing; local sedation was practised, and iodoform freely used. Constitutional medication was considered of much importance to quiet cough and favor cicatrization, promote sleep, relieve restlessness, and to nurse and nourish the enfeebled body. Change of climate was also considered essential. By carefully combining these means, a patient threatened with death by starvation from painful deglutition, was restored to strength and comfort. One vocal cord had been almost entirely eaten away, firm cicatricial tissue forming the excavation.

He showed there was an analogy between certain forms of phthisical ulcers in the larynx and simple superficial ulcers in the mouth; that sores in the mouth were sometimes produced by the irritant action of perverted buccal secretions upon slight wounds. A pellicle of shellac varnish, or an eschar, afforded protection and facilitated healing. If the lesion happened upon a part in frequent motion, it was converted into a severe ulcer, producing a train of constitutional symptoms resembling in certain respects those of ulcerative laryngeal phthisis. He believed the incipient wound of phthisical ulcers could be caused by a violent cough; constant motion, and acrid discharges from the lungs, completed the analogy. Certain forms of phthisical ulcers, easily recognizable, could be cured. Far advanced phthisical ulcerations invariably proved fatal.

A new laryngeal powder-blower was exhibited, for the treatment of laryngeal phthisis.

The papers of Drs. Ingals and Jarvis being upon the same subject, were then discussed together.

Dr. S. Johnston remarked, regarding the cases of laryngeal phthisis, that the only one which had come under his observation where a cure had been effected, was that of a lady who had consulted him some years since, complaining of a chronic cough. Laryngoscopic examination revealed an infiltrated epiglottis with its under surface studded with punctæ, which subsequently coalesced, forming a round ulcer. Physical examination revealed no signs of phthisis. He used a spray of one grain of sulphate of zinc, and three grains of carbolic acid in solution; and internally a mixture of hypophosphite of lime and soda with glycerine and infusion of cascarilla; there was no application of powders or pigmentæ. In three weeks the ulcer was healed. The patient had recently died of diphtheria, and this disease manifested itself especially upon the surface which had been attacked some years before, and which had healed.

Dr. Donaldson stated that he thought persons suffering from laryngeal phthisis could be relieved by local treatment, astringents combined with sedative sprays, powders of iodoform, and antiseptic inhalations combined with the local treatment. In case deglutition is painful, the patient should be sustained by the injection of food through small œsophageal tubes. He spoke of a case where he had fed a patient daily in this manner for six weeks; the case apparently recovered, and two years afterward was alive, and was now living somewhere out west.

Dr. Bosworth said it seemed to him that in the whole question of the treatment of laryngeal phthisis, there is the element of doubt of the correctness of diagnosis. What constitutes laryngeal phthisis? Are not many cases of this disease reported which are nothing more than superficial erosions of the laryngeal membranes? He wished there was some way in which the matter could be decided. In his own view, there was but one morbid process in the larynx which constitutes this disease: this process manifests itself in every case in virtually the same way, and runs the same course. It is manifested in three stages: first, the stage of inflammatory thickening occurring in the large majority of cases in the arytenoid cartilages. It constitutes what is generally called the club-shaped arytenoids. This same inflammatory swelling may, however, make its appearance on the epiglottis, where, from its location, it becomes an exceedingly grave matter, constituting what is called the epiglottic form of the disease. In a certain proportion of cases, this swelling develops on the ventricular bands, but never,

he thought, on the vocal cords. In this state of the disease, tubercle is not present, as has been so conclusively shown by Dr. Cohen. In this state, then, he thought there should be no question as to the curability of the disease, for he certainly found in his own experience that a cure might almost be promised. The second stage is marked by the development in the swollen membrane of small, rounded, gray spots, apparently just beneath the surface, they are easily seen on inspection dotting over the surface. If tubercle is ever inspected by the naked eye, these spots are the tubercle. I have watched this process on the tongue, and have watched the evolution of these little masses, and have seen them break down and develop into small points of ulceration, which constitutes the third stage. These points extend their borders, and then develop the true tubercular ulcer. Now, this tubercular ulcer is unmistakable: it is a wasting process, superimposed upon an interstitial growth, so that we have the apparent incongruity of an ulcer resulting in a greater bulk than the original contour of the part. The surface of the ulcer is coated with ropy mucus, never with pus. The appearance is very light. All cases of this disease which have come under my notice conform to this course. As to the treatment, some years ago he had written on this affection, and had then insisted that no application should ever be made which gave pain; and secondly, the first indication of what would relieve pain, and promote the well-being of these cases, was to carry out the following: First cleanse the part with alkaline spray, then apply morphine to relieve pain, and, third, apply iodoform; by this plan he has seen a number of cases recover, he believed, as the result of treatment. The above plan should be carried out every day.

DR. J. SOLIS COHEN had reached the room so late as to have heard the last sentences only, and was, therefore, unfamiliar with the train of thought taken in the paper, and hardly prepared to join in its discussion. In reply to a direct question from the President, he stated that in his own experience cures were exceedingly rare, and these cases could not be recognized beforehand. His own experience was that so many cases of tuberculosis of the larynx indicated so many funerals.

DR. KNIGHT said that he regarded a laryngeal implication a very unfavorable complication of pulmonary phthisis. Although an arrest of the laryngeal disease and relief of the local symptoms may occur, the patient goes down hill from the manifestation of the disease in other organs. Mild treatment, principally cleansing the parts, undoubtedly did, oftentimes, great service in relief to the patient and in facilitating the arrest of the local disease.

DR. ASCH said that his results, unfortunately, had been the same as those of most of the speakers, and it would afford him great pleasure if there could be discovered a specific treatment for this most unfortunate disease; he feared it had not yet come to light. He had had some cases in which the ulcers were cured, but in each of these there had always been some specific trouble, hereditary, or acquired, which accounted for the ulcerations. In all these cases there had been extensive pulmonary trouble, but the disease of the larynx was due apparently to other complications.

DR. LINCOLN said he desired to make a suggestion in regard to the indications for the use of iodoform in cases of laryngeal phthisis, which may serve to explain the different opinions entertained as to its utility, and especially the discouraging opinion held by Dr. Ingals as to its advantages. Some ten years ago, he published a series of cases illustrating the utility of applications of iodoform in powder or spray (ethereal solution). He believed that he had here stated that in cases of laryngeal phthisis, iodoform was chiefly useful where there was a solution of continuity, *i. e.*, where there was ulceration, and not where there was hyperplasia with engorgement of the bloodvessels and dryness of the mucous membrane. He would further suggest as an addition to the mild and sedative spray of carbolic acid, tannin, or morpheous solution, the addition of a few drops of essence of peppermint (two to four drops to the ounce of solution). The constant and universal testimony of his patients as to the comfort derived from the use of this medicament is most gratifying, and leaves no doubt as to its usefulness.

DR. MAJOR stated that, in his opinion, if laryngeal phthisis be truly a local tubercular development, it is the result of a tubercular condition of the system; if an indolent ulceration occurring in the tubercular subject, it was the result of systemic depravity arising therefrom. It seemed reasonable to suppose that any circumstances whatever which would improve the general health and check the development of pulmonary phthisis would also have the same influence on the presence of tubercle occurring in the larynx. It was generally conceded that a certain pressure and moisture of atmosphere were necessary to develop tubercle. Now if the patient were removed to an atmosphere sufficiently dry and rare to hold in check pulmonary tuberculosis it would have a like good effect on a laryngeal condition.

DR. DUNCAN had seen many of the cases of laryngeal phthisis in which the laryngeal ulcers were healed by the prolonged, daily, mild applications mentioned by Dr. Bosworth, and he could bear testimony to the fact that the ulcers disappeared and the laryngeal symptoms were removed; this did not stop the advancement of the pulmonary phthisis, but removed the annoying and painful symptoms in the larynx.

DR. INGALS, in closing the discussion, said that he was much gratified in the debate which had been excited, and considered that the object of his paper had been accomplished. The question of diagnosis was raised by Dr. Bosworth, but he was not prepared to accept the dictum that the peculiar boggy swelling necessarily accompanied the disease. He thought that when the evidences of pulmonary phthisis were unquestionable he would not hesitate to pronounce coexisting laryngeal disease of the same character, even though the swelling did not appear; but when this swelling exists together with the pulmonary signs, the diagnosis is certain. He noticed, from what had been said, that prolonged mild treatment seemed the most satisfactory, and here the key-note had been struck, it was true. With Dr. Cohen, he believed that quite a large number of cases would get well if given time. His fear that iodoform is of little use in these cases, is due to the fact that patients in whom he had used it continuously for a long time had shown no local evidence of change until other remedies had been substituted.

The patient he referred to who was sent to Colorado, was sent there because of the pulmonary disease. He believed that the dry air is not desirable in most cases where the larynx is tuberculous.

DR. JARVIS said that the difference in appearance in the phthisical and syphilitic ulcer is distinctive and there was no excuse for confounding the red areola of the latter with the pale-grayish appearance of the former. The coexistence of the gray ulcer and the pyriform thickening over the arytenoid with the phthisical pulmonary signs, also tends to confirm the correctness of the diagnosis, inasmuch as inhalations have no curative effect upon the simple traumatic ulcer in the mouth. He failed to see what benefit could be derived from their use in the treatment of the ulcers of laryngeal phthisis. As iodoform so markedly benefited the simple buccal sores, so we might find it a valuable application in ulcerative laryngeal phthisis.

PARESIS OF THE CONSTRICTOR MUSCLES OF THE PHARYNX, SIMULATING SPASMODIC STRICTURE OF THE ŒSOPHAGUS, WITH REPORT OF CASES.

Dr. F. H. Bosworth reported some clinical observations made on five cases under his care which simulated spasmodic stricture of the œsophagus. He considered the condition as purely myopathic and not true paralysis, like that following diphtheria for instance, or that in glosso-pharyngeal palsy or other neurotic disease. They were in adults, two male and three female. The condition was associated with some hyperæsthesia, but to mechanical and electrical stimulation there was a decided loss of contractility. The treatment recommended was rest, the interdiction of solid food, strychnia, fresh air, and bathing, and in all but one case this had been successful.

Dr. Cohen had regarded such cases chiefly as hysterical, and the greatest success in treatment under his own care had followed moral treatment, enforced swallowing under the supervision of a competent nurse, himself being present at the earliest attempts.

Dr. Knight remarked that the loss of contractility of the muscles under electrical stimulus in the cases reported, made them distinct from those coming under his own observation. Most of the cases he had had were due to hyperæsthesia, and were overcome by passing bougies, and were relieved by administering sedatives and remedies calculated to relieve abnormal muscular action.

Dr. Langmaid said that if his cases had been similar to Dr. Bosworth's, he would say that he had always been satisfied with the results obtained by the repeated passage of graduated bougies.

Dr. Bosworth said that hysteria was excluded from the diagnosis by the fact that there was sluggishness of the muscle, not only in respect to electricity, but to mechanical stimulation. The hyperæsthesia had been suspected of causing the symptoms, but in some cases there was anæsthesia; in most of these, undoubtedly the mucous membrane was unduly sensitive, and with decided feebleness of the muscle.

Adjourned.

The Annual Dinner of the Association was given at Delmonico's, in the evening at 7 o'clock.

Tuesday, May 22d.—Second Day.

Morning Session.

Dr. T. R. French, of Brooklyn, read a paper on

PHOTOGRAPHING THE LARYNX.

He stated that, with the assistance of Mr. George B. Brainerd, an expert amateur photographer of Brooklyn, he had made during the past year numerous experiments with various forms of apparatus.

He demonstrated last year that the larynx could be photographed, but with that process the throat mirror and camera were in fixed position, and the head of the patient had to be drawn up to the mirror and arranged to suit its position. That of course necessitated a very tolerant throat in order to succeed. We realized that photographs taken in that way could have but a limited value in the study and demonstration of diseases of the larynx, and, therefore, our objects this year have been:

1. To simplify the procedure, and so convert that which before was only an interesting experiment, into an operation of practical utility.

2. To take a better photograph. In the fulfilment of both of these objects he believes that they have been successful, for as he showed further on, they have adopted a hand camera with which the larynx of persons having only fairly tolerant fauces, can in the majority of instances be photographed by any expert laryngoscopist; and presented a number of photographs taken with the stationary apparatus, which are an improvement upon last year's results.

The sources of illumination used in the experiments made this year were unaided sunlight, condensed sunlight, oxyhydrogen, magnesium, and electric light. The experiments with the electric light were made with one of Wood's 6000-candle power focussing lamps.

The best results were obtained from condensed sunlight with the plane reflector.

The stationary and hand cameras were then shown, and the procedures illustrated and explained. Many photographs of normal larynges taken with the stationary camera, and normal and diseased larynges taken with the hand camera, were exhibited. Those taken with the hand camera are so small, that unless enlarged, can only be satisfactorily seen with a magnifying glass.

Beside normal larynges, the photographs showed perichondritis of the arytenoid cartilage and swelling of the ventricular band in phthisis, growth in the larynx, and approximation of the ventricular bands during spasm. Also portions of the posterior nares showing hypertrophied membrane from catarrh.

The paper concluded as follows: The results of the experiments made this year may be summed up as follows:

1. Better photographs have been taken with the stationary apparatus than those of last year.

2. A camera has been so adapted that it can be held in the hand and be quickly placed in position. This makes it possible to photograph the larynx in patients whose fauces are only moderately tolerant.

3. The photographs are taken instantaneously by a drop-shutter, thus making it possible to photograph the larynx even if the parts are in motion.

4. The parts reflected in the mirror are alone exposed, thus avoiding the confusion which arises when the mouth and lips are included and out of focus.

5. As the apparatus is so small, and the exposure is made instantaneously, if desirable, photographs can be taken without the patient being aware of the object of the procedure.

6. Several diseased conditions of the larynx have been photographed. This is an important step in advance, for we believe that it is the first time that it has been accomplished.

7. Portions of the rhinoscopic image have been photographed.

The photographs show, among other things, hypertrophy of the mucous membrane covering the posterior portion of the nasal septum. So far as we are aware, this is the first time that any portion of the posterior nares has been photographed.

By request of the author, discussion on the paper was postponed until the end of the morning session, in order that Fellows might have an opportunity of examining the photographs presented.

In the absence of H. A. Johnston, M.D., of Chicago, the author of the paper, Dr. MacKenzie, of Baltimore, was appointed to read his communication on

FIVE CASES OF CONGENITAL TUMOR OF THE LARYNX.

Dr. H. A. Johnson, of Chicago, reported these cases, because the subject has not received the attention at the hands of laryngologists which it deserves. With the exception of the monograph of Causit, published in 1867, there has been but little attention given to this class of cases. It seems probable also that congenital troubles of this character escape detection. In the absence of articulate speech, the abnormal condition of the voice is not always recognized. It is also quite possible that cases of laryngeal tumor are occasionally taken for thymic asthma, and possibly for cardiac malformations.
